THE ENGINEERING RECORD.

Volume XLVI., Number 16.

TABLE OF LEADING ARTICLES.

The Compensation for Engineering Services...... 361
The Weston Aqueduct of the Metropolitan Water-Works, Boston.—I. (Illustrated)......... 362
A Four-Truss Double-Deck Railroad Bridge.—II. (Illustrated)..................... 364
The Use of Wood Pavements Under Heavy Traffic 366
An International Committee on Street Hygiene. 367
The Mechanical Plant of the Prudential Buildings, Newark, N. J. (Illustrated)............ 367
Report of the Chairman of the Committee on Sewerage and Sanitation..................... 372
The Scope and Purpose of the Irrigation Investigations of the Office of Experiment Stations. 374
Interurban Road Improvements................ 377
A Self-Contained Dryer (Illustrated)........... 377

The Engineering Record, conducted by Henry C. Meyer, is published every Saturday at 21 Park Row, New York. Its opinions on technical subjects are either prepared or revised by specialists.

Subscriptions are received and single copies supplied by the International News Company, Breams Building, Chancery Lane, London.

The subscription rate is $5 a year for the United States, Canada and Mexico, and $6 for other countries in the Postal Union. Remittances should be made by check, New York draft or money order in favor of The Engineering Record. No responsibility is assumed for payments made otherwise, except those for subscriptions to the International News Company.

The Compensation for Engineering Services.

Whenever all other subjects of engineering controversy, the proportions of concrete, the value of reheaters, and the like, are finally settled, there will remain for discussion the ancient topic anent the compensation for engineering services. It is ever-present and always pertinent—of interest to the chief as well as the rodman, and, of course, one which all engineers agree can only be settled properly by raising salaries and fees all around. The public, unfortunately, does not always think as it should, and some recent instances of its blindness to the money value of engineering are worth considering.

The first instance, strange to say, is from a Pennsylvania county where enough good engineering work has been done and paid for in the past to warrant some confidence in the existence of proper general knowledge on this important subject. Two bridges were needed, and the county commissioners were sufficiently intelligent to retain an eminent consulting specialist to make the necessary surveys and plans for them. No objection seems to have been raised to his work, but his bill of $1,907.20 for services rendered has apparently reduced the commission to nervous prostration. It is claimed by them in the local press that home talent would have done the work for $50 and that $150 for traveling expenses was the maximum additional charge that any one was warranted in making.

Of course $1,907.20 is somewhat larger than $50 plus $150, but it may not prove so much greater in the end. The Engineering Record formerly gave considerable space every month to obituary notices of county bridges of home design, but as these mortuary notes were not cheerful to anybody and seemed to have no particular influence in raising the standard of such work, their publication was stopped. The material for them is still received in a steady stream, however, and the reason for its ample amount is to be found in those $50 plans. A man who will design a $10,000 bridge for $50, and make the surveys, cannot furnish the practical experience and knowledge which will insure that the plans call for a structure strong enough for road rollers and electric cars as well as ordinary traffic, economical in material, and detailed so as to go through the shops and be erected at a minimum expense. Poor design may mean accidents, which are expensive, and high shop and erection charges, which sometimes run up in a surprising way when the home talent tries hard to be original in conception and bold in execution.

Another instance in consulting practice, but of an opposite nature, recently came up for discussion with The Engineering Record. One of the leading engineers in the country received a call from a stranger one Saturday evening, just after returning from a tiresome tour of inspection of work under his charge in a number of States. The stranger produced numerous blueprints and a voluminous report relating to an engineering project calling for an expenditure of three-quarters of a million. He proposed taking a half interest in the project and a leading Wall Street firm would take the other half if the engineer would report favorably on it. The answer was wanted at 2 o'clock the next day. Out of consideration for the financial house, the engineer gave up his needed rest, worked all through the night and the next morning, and then reported decisively against the undertaking. When he mentioned that his fee for thus saving the waste of $750,000 was the large sum of $100 The Engineering Record's feelings were not fit to express. That man ought to consider the famous advice of Rufus Choate to a young lawyer in a somewhat similar case: find out how much the client has been saved and then make the charge somewhat smaller.

The most interesting aspect of the subject has recently been brought up in a letter to the New York Rapid Transit Commission from Mr. William Barclay Parsons. It relates to the salaries of the principal assistant engineers and the assistant engineers of the highest grade. The younger men, who have opportunities for promotion and are without responsibility, are stated to be adequately paid, but the grades mentioned do not receive salaries equal to those of other city employes performing the same work and having far less responsibility. The four principal assistant engineers average $189 per month each and together have responsible charge of work amounting to $7,000,000. The twenty assistant engineers average $150 per month each, and are in responsible charge of work worth about $2,000,000. Mr. Parsons recommends strongly an increase in these salaries, and it is to be hoped the Commission will grant the request.

In making the recommendation, Mr. Parsons points out clearly the two conditions which govern the compensation of an engineer working on a salary; first, the responsibility put upon him, and, second, his opportunity for advancement. The work to be done fixes the salary, not the engineer's ability to do better work. The man who is merely a high-class skilled laborer in the field or drafting room should not expect the compensation of the man who has to be responsible for the work of others as well as himself. The American Society of Civil Engineers has very clearly indicated this in its requirements for admission to its two grades of active membership, which read as follows: "A member shall have been in the active practice of his profession for 10 years; he shall have had responsible charge of work for at least five years." "An associate member shall have been in the active practice of his profession for at least six years, and shall have had responsible charge of work as principal or assistant for at least one year." The second factor in fixing salaries is the opportunity for promotion offered in a position. So long as advancement is possible, the rate of compensation must necessarily be somewhat lower than that for similar work where there is no chance of promotion. That is a matter not always recognized, and it is surprising to notice the astonishment of some chief engineers whose good men leave them to accept the same or even lower salaries elsewhere. These chiefs forget that ambition is a great incentive to good work, and when ambition is killed it is possible to keep good men only by paying them well to give up their dreams of great things. Really good men live in the future while working in the present, and the failure to grasp this fact is one of the failings of the engineer as an employer. In fact, when all aspects of the matter of compensation are considered, it is probably safe to say that the older engineers are more responsible for the present low average rate than any other single influence.

The Proverbial Jersey Mosquito occupies an important position in the annual report of the Board of Health of Montclair, N. J. The following extract from this report may be of interest to householders: In the great majority of cases, houses breed their own mosquitoes, and the breeding places are usually pools, drains, empty tin cans, sagged gutters, and rain barrels on the premises. This is true because mosquitoes, with the exception of one variety, tend to abide near their breeding places.

The Water-Works Problem of New York is so serious that many citizens interested in public affairs are talking about the failure of the present administration to begin plans for the new-supply works which must inevitably be needed before they are completed. So much has been printed in The Engineering Record about the situation in New York that it is unnecessary to refer to it again, but some comment must certainly be made concerning a proposal by the City Comptroller that the Mayor should appoint a commission to consider means of increasing the supply. The proposal is to have the Water Commissioner act ex officio as chairman, Mr. John R. Freeman, M. Am. Soc. C. E., is to be a member, the Merchants' Association is to select another, and a third is to be chosen by those previously appointed. It is to be hoped nothing will come of this proposal for it is not well-considered. The work of Mr. Freeman and the engineers who conducted the investigation for the Merchants' Association a few years ago was so thorough that the design of a new system can be started as soon as the word is given by the Mayor, provided the law officers will first definitely decide whether it is safe to go to the Housatonic River basin for the supply. At present the situation is wholly a legal one. The Housatonic supply is the best, all things considered, but its availability is involved in complicated legal tangles; the second choice is the Hudson near Poughkeepsie, which will furnish water of good quality after filtration. Both projects have been so well studied that either can be developed in a year or so, provided one competent engineer is put in charge of the work. A commission will simply cause delay without any gain. The city now has a shrewd public-spirited Water Commissioner with good engineers to assist him in managing the existing works. The logical way to carry out the design of the new system, when the Mayor makes up his mind to begin the work, is for him to authorize the Commissioner to retain a consulting engineer for the purpose. Just what formalities must be adopted in executing this plan, it is safe to leave to Colonel Monroe, whose brief career as head of the New York water department indicates that he knows what to do and how to do it.

The Weston Aqueduct of the Metropolitan Water-Works, Boston.—I.

By Alfred D. Flinn, Engineer, Designing and Drafting Department.

In The Engineering Record for May 4, 1901, there was published a brief general description of the Weston Aqueduct, together with extracts from the specifications for earth embankments and tunnel work, and a few details were illustrated. This aqueduct has been designed for a capacity of 300,000,000 gallons per day and when completed will extend from the dam of the Sudbury Reservoir in Southborough to the bluff on the west bank of the Charles River, in Weston, at the westerly limit of the metropolitan water district, a distance of nearly 13½ miles. The construction of the aqueduct was begun in the spring of 1901 and substantially the whole work, excepting the superstructures of the controlling chambers, is now under contract. For the most important contract prices, the reader is referred to the contract news columns of The Engineering Record of September 7 and November 30, 1901, and March 15, May 10, June 21 and August 2, 1902.

The aqueduct comprises the head works at the Sudbury Dam, consisting of three lines of 60-inch cast-iron pipes, each about 480 feet long, with connecting chambers; 12,266 feet of masonry cut-and-cover construction and 5,879 feet in three concrete-lined tunnels, on a grade of 4 in 5,000; 130 feet of flat-arched, special steel and concrete construction under a railroad; 30,725 feet of masonry cut-and-cover construction and 5,686 feet in one concrete-lined tunnel, on a grade of 1 in 5,000; an open channel 1,366 feet long; an equalizing reservoir about 4,000 feet long; 5,125 feet of masonry cut-and-cover construction and 600 feet in one concrete-lined tunnel, on a level; and two inverted siphons of 90-inch riveted steel pipes, the first 3,603 feet long across the Sudbury River valley, and the second 1,123 feet long across Happy Hollow, two depressions which interrupt the grade of the 1:5,000 portion of the aqueduct. The masonry portions of the aqueduct, including the tunnels, have horse-shoe shaped cross-sections. Where the gradient is 4 in 5,000, the horizontal diameter is 10 feet and the vertical diameter 9 feet 3 inches; where the gradient is 1 in 5,000 and in the level portion, the horizontal diameter is 13 feet 2 inches and the vertical diameter 12 feet 2 inches.

For convenience during construction, the aqueduct was divided into fifteen sections and the reservoir into two. The department engineer's office was established at Saxonville, about the middle of the length of the line, and branch offices for the division engineers and the field parties located at other convenient places near the work. At the Saxonville office a complete cement-testing outfit was set up. Samples of cements are taken in small paper bags and brought to the office in baskets or boxes.

The contract for Section 1, the headworks, was awarded to T. H. Gill & Co., of Somerville, Mass., June 16; contracts for Sections 2, 3, 6 and 12, including tunnels Nos. 1, 2 and 3, were awarded, on May 9, 1901, to Shanahan, Casparis & Co., of Louisville, Ky., and Columbus, O.; Section 4 was let to P. McGovern, of Boston, and Section 5, including the crossing under the railroad, to Bruno, Salomone & Petitti, of East Boston, on May 6 and 8, 1901; Sections 7 and 9, the steel pipes, were let, on March 7, 1902, to Edward Kendall & Sons, of Cambridgeport, who sublet the earth and masonry work connected with the pipe lines to Winston & Co., of Clinton, Mass., with whom contracts for Sections 8, 10, 11 and 15, including tunnel No. 5, were made on August 28, 1901; Section 13, including tunnel No. 4, was let, May 8, 1901, to M. H. Keefe, of Yonkers, N. Y., but satisfactory progress not being made, the work was reorganized later and Mr. Keefe's interests assumed by the Columbus Construction Co.; and the contracts for Section 14, the open channel, and Sections 1 and 2 of the reservoir, were awarded to Nawn & Brock, of Boston, on November 26, 1901. Sections 2 to 4 inclusive are of the smaller cross-section. The work is now being actively prosecuted on all the sections and the contracts stipulate that all the work shall be completed before August 1, 1903. It is already necessary to be able to convey a larger supply of water into the metropolitan district.

The Weston Aqueduct has involved an unusual amount of interesting detail in its design, and descriptions of some of these details which may have value for the readers of The Engineering Record will be given in this article. The work will be in an interesting stage to visit at any time during this autumn and next summer.

The method of building foundation embankments for the aqueduct, where required by depressions in the ground, has proved very successful. It is substantially the same method as was employed in constructing the Wachusett Aqueduct and is fully described in a quotation from the specifications given in The Engineering Record of May 4, 1901. Embankments formed in this manner, even when the material was fine sand, have been found so solid that, after removing the few inches of surplus on top, which is unavoidably kept loose by the trampling of the horses' feet, a strong blow would not drive the point of a shovel more than an inch or two into the bank. No trouble whatever has been experienced from settlement of the masonry even on some high embankments. One of the illustrations shows the method of flooding the foundation embankments for the aqueduct, after they have been built. The careful selection of materials and thorough rolling in thin layers, however, are mainly depended upon for compacting the embankments, and the flooding is sometimes omitted.

Tunnels.—There are five tunnels, all of which are being driven from the portals only, without intermediate shafts. Tunnel No. 1, 704 feet long, is through very compact clay and gravel, known as hardpan, which will stand well without support for a short time after excavation. Two schemes for driving and lining the tunnel were proposed: first, to make the lining of three rings of brick on the sides and arch, the excavation being cut to just the right shape and size for the brickwork with a collar joint of mortar, and completed for a few feet at each shift, the masons to follow the excavators immediately; second, to drive the tunnel with three-stick timbering and lagging for the upper part, the sides being unsupported, making the hole somewhat larger than in the first scheme and afterwards placing a complete Portland cement concrete lining. In either scheme, the invert was to be of Portland cement concrete and placed last. The contractor's methods and organization have not been such as to make the first scheme successful and so a modification of the second is being employed.

Two of the remaining tunnels are of the smaller cross-section and all four were expected to be mainly through rock and to be lined completely with Portland cement concrete. The concrete arch will vary in theoretical thickness, in the tunnels of the smaller section, from 7 to 15 inches, and in the larger tunnels from 8 to 18 inches. The inner portions of the linings are to be of 1:2½:4½ concrete and the backing of 1:3:6, the concrete being filled against the sides of the rock excavation except that stone fragments will be allowed to some extent for filling large cavities over the arch.

Tunnel No. 4, however, developed unexpected conditions at its westerly portal. It had been anticipated, as the result of rod soundings, that this tunnel would be in solid rock, and so the portal cut was made and the tunnel excavation started where the depth over the arch was about 18 feet, although at this place the rock was only at the level of the springing-line and the upper part of the excavation was in stiff clay, the expectation being that the rock surface would soon rise, as the few soundings that had been made in this part of the line and other indications seemed to point to such a conclusion. Instead, however, the rock surface continued approximately level for a long way, and did not rise above the arch so as to bring the whole cross-section in rock until the tunnel had been driven about 915 feet. Timbering was used, of course, from the beginning, but in the expectation that the cut would soon be entirely in rock, much lighter sticks were put in than were adequate, a cap and two batter posts 8 inches square. These soon began to crush and sag, and so heavier pieces were used in the advance work, 10x10-inch and 10x12-inch hard pine caps and posts, with 3-inch lagging, and the earlier timbering was supplemented or replaced. Various methods of timbering and various sizes of timbers were used at different places in this part of the tunnel, according to the position of the rock and other conditions. Each frame of timbers is numbered and a record kept of it, levels being taken from time to time to detect settlement. Some of the caps have sunken as much as a foot, and some of the lighter ones first used have bent badly and a few have broken. About nine months were spent in excavating these first 915 feet. Once for a few feet along the tunnel, the rock dropped just below the elevation of the invert, and in two places for short distances it rose just above the crown of the arch. The rock is a seamy, broken granite, hard to work, and the clay is so hard as to require light blasting, but is so intersected with sand seams that it cannot be trusted to stand without substantial support. One sand pocket encountered in the side of the tunnel yielded water so freely and caused so much trouble that it took nearly a week to drive the bench 6 feet.

Through the clay and rock portion of the tunnel, the heading was usually kept about 40 feet in advance of the bench, but this distance varied from 20 to 120 feet. Two Ingersoll-Sergeant drills were used on the bench and one or two in the heading according to the position of the rock. The timber caps were set high enough to leave 6 inches to 1 foot clearance over an 18-inch arch.

At one time in the spring when the writer visited the west end of the tunnel, work was being carried on continuously by two 11-hour shifts of 22 men each. The average progress was about 30 feet per week, but some weeks the heading was driven over 40 feet. Since the section has been entirely in rock the average weekly progress has been about 36 feet and there have been no features of unusual interest connected with the excavation. At first materials were taken into and out of the tunnel by horses and mules drawing cars on 20-inch gauge tracks. A 3-foot gauge track was afterwards laid in the tunnel and on the dump. Mules are still used to haul the cars out to the point where the arch is being built, but an electric trolley motor moves the cars from this point on to the dump.

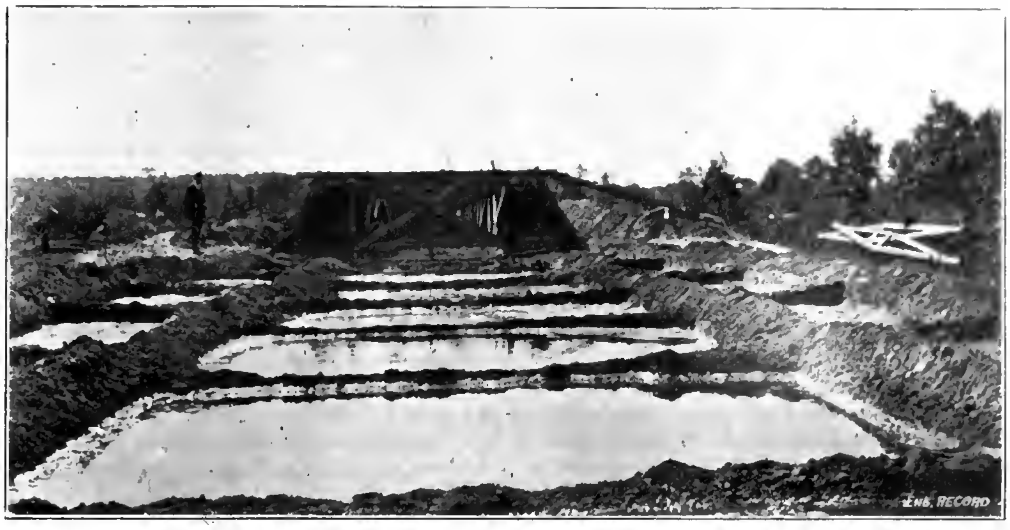
Compressed air is used for the drills and for the ejectors employed for draining the tunnel. The slope being toward the heading at this end pumping is necessary, and so sumps are dug and the water taken from them by the ejectors. A 10-inch galvanized ventilating pipe has been placed on one side of the tunnel about 6 or 7 feet above the invert. The tunnel is lighted by incandescent electric lamps. The power plant consists of two Ingersoll-Sergeant compressors of 657 cubic feet per minute capacity, two 60-horse-power and one 100-horse-power return tubular boilers, a 60-horse-power Westinghouse vertical engine and a 500-volt 70-kilowatt Thomson-Houston dynamo. The compressors are arranged to stop automatically whenever the pressure in the air mains reaches 100 pounds per square inch. The working steam pressure in the boilers is 100 pounds per square inch.

It was the original intention to have the placing of the concrete lining follow the excavating as soon as the tunnel should have been sufficiently well started to have the blasting at a safe distance, but the work was delayed. Finally, a beginning of the lining was made at the portal but the settling of the timbers and the nature of the materials so greatly increased the difficulties of this work that it was decided to uncover for about 75 feet farther and place the concrete in the open cut.

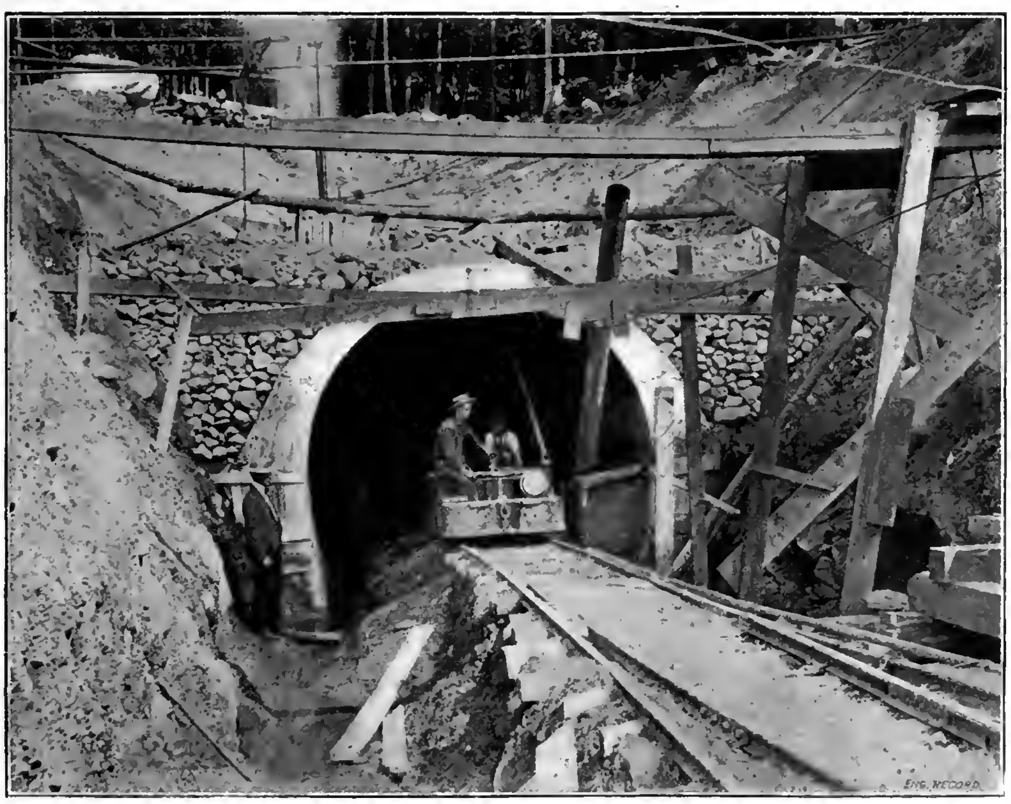
Stone bins, a stone crusher and concrete mixing boards have been set up near the portal. Selected stone from the excavation is dumped upon platforms near the crusher. The concrete is mixed outside the tunnel and brought in on the cars. For setting these forms for the lining, only the center line and the grade of the springing line of the finished arch are given. For the regular concrete tunnel lining, a traveler was used for a while, except in those places where the timbers had to be so placed as to prevent; but this was given up and various other means and methods have been employed from time to time. At two places where there was even more trouble than usual with the timbering, heavy brick lining was built for short distances.

The line and grade party consists of four men, who have also spent portions of their time on adjacent sections of the aqueduct. The conditions necessitated running the line, both over the hill and in the tunnel, on offsets. In the tunnel the line is marked mostly by horseshoe nails driven into the cross timbers, either caps or braces, as is most convenient in any case, but occasionally a chestnut hub is set well below grade in the bottom and covered with a stone. The nails have holes bored through their heads, through which a wire or string can be passed in order to suspend the plumb-bob. Stations are marked every hundred feet by white enameled tin labels about 4x6 inches in size, on which 3-inch black numbers are painted. These labels are prepared by the field party at odd times when in the office. They are tacked to the timbering about 7 feet above the bottom of the tunnel. The line is carried forward with a transit by reversing from a backsight. As thus projected with necessarily short sights, it has been checked by running in repeatedly from the base line outside with long sights, the first sight from the portal being 300 feet, the second 250 feet and the third 150 feet. The line was run twice and the instrument reversed six times at each instrument point. The target used is a piece of white celluloid upon which parallel black lines have been painted with the spaces increasing in width from the center of the target, similarly to the targets of some precise level rods. These targets were illuminated during use by the direct light of an acetylene bicycle lamp.

Tunnels Nos. 2, 3 and 5 have so far developed no unusual features. They are respectively 3,015 feet, 2,160 feet and 600 feet long. Tunnel No. 5 was completed late in the spring, having been driven entirely from the eastern portal.



Flooding Foundation Embankments for Aqueduct, for Final Settling, after Rolling in Thin Layers.

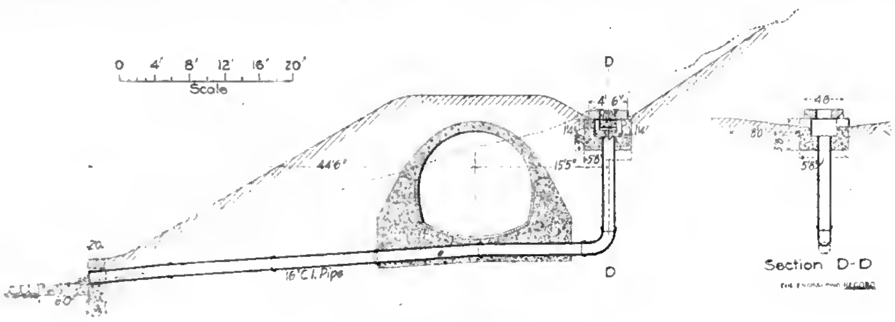


West Portal of Tunnel No. 4 Showing Cross-Section of Concrete Lining.

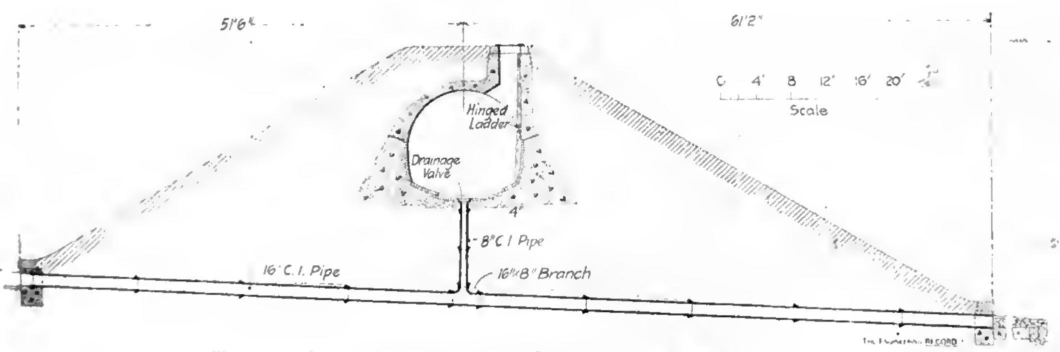
Culverts, Blow-offs and Manholes.—There are 39 culverts along the aqueduct, or somewhat more than an average of three per mile. Nine are siphon culverts, three are carried over the arch and twenty-seven are free draining beneath the aqueduct. Twelve are masonry and the others cast-iron pipes, the latter being used wherever a waterway less than two feet square was sufficient, or, in other cases, if more economical. Twelve inches was the minimum diameter used, with one or two unimportant exceptions. Pipe culverts have masonry head walls at inlet and outlet. Siphon culverts have masonry sand-catchers, or sumps, at their inlets, varying in area and depth according to the estimated needs of the situation, but always large enough for a man to clean them out with a shovel, the minimum size being 3x4 feet. Wherever the bottom of the sump would always be wet, it was made of 3-inch spruce planks; in other cases concrete was used for the bottoms as well as for the walls. Both inlet and outlet of each siphon culvert were provided with stop-plank grooves so that the culvert could be pumped out for cleaning and inspection.

In inconspicuous locations, the head walls of culverts were made either entirely of concrete or else with simply a granite coping stone; but wherever exposed to frequent view, as where near a highway, they were faced with a good quality of granite ashlar. Light dry rubble stone paving, averaging about 8 inches in thickness, was used at the inlets of most culverts to a moderate extent, while at the outlets, heavier paving laid on broken stone or coarse gravel, having frequently a total depth of 24 inches next to the head wall, was used to such an extent as to insure the impossibility of the end of the culvert being undermined by the water, the paving diminishing in thickness somewhat as the distance from the head wall increased. Masonry culverts were usually made wholly of Portland cement concrete, but in a few places where particularly exposed to freezing, the arches were made of brick. The arch, also, of one large culvert under a highway, where the earth cover was shallow and the loads would come upon it soon after construction, was built of brick. In two cases in which large brooks had to be taken under the aqueduct in siphon culverts, in order to avoid either a very wide flat arch or else an uncomfortable depth of digging in a wet place, twin passageways were constructed with a thin partition wall.

Pipe culverts were usually laid on a straight line from end to end, but wherever this was not feasible the change of direction was, with one or two exceptions, reduced to one vertical curve made by means of a standard special casting. In all cases the pipes were laid in trenches cut below the original surface of the earth. Where the aqueduct is in excavation this generally permitted the culvert to be placed very close to the bottom of the aqueduct and in many cases the pipe was partially or wholly included in the masonry of the aqueduct bottom. Where the aqueduct is on embankment the culvert is sometimes a considerable distance below the bottom of the aqueduct, and, if blow-offs occurred in such positions, the connection from the blow-off valve to the culvert was made with a vertical cast iron pipe composed of short lengths, with bell and spigot joints, arranged to allow for a slight settlement. In one place where the aqueduct is built partly in excavation and partly on embankment, along the side of a very steep hill, the inlet to a pipe culvert is a vertical pipe 13 feet high, the water dropping through this pipe to a nearly horizontal pipe passing beneath the aqueduct. Typical masonry culverts were illustrated in The Engineering Record for May 4, 1901; two of the accompanying drawings show the pipe culverts.



Special Pipe Culvert.



Typical Pipe Culvert, with Blow-off and Manhole.

At 13 free-draining culverts under the aqueduct, connecting with suitable water courses, blow-off valves were set in the bottom of the aqueduct to aid in draining out ground water during construction and removing dirty water during the periodic washings of the aqueduct after it shall have been put into service. In one part of the line where there was an unusually long distance between two culverts, a blow-off was provided although there was no water course into which it could discharge. Advantage was taken of a large gravel pit to turn the discharge into the permeable material, through which it could drain away, without detriment to anyone, reaching finally a lower and somewhat distant brook. Although several large brooks cross the line of the aqueduct, at only one or two of them will it be practicable to discharge such considerable quantities of water as would be of material assistance in emptying a portion of the aqueduct, and even then the water would have to be let out with great care in order not to flood or otherwise injure private property. These blow-off or drainage valves have a clear opening of 8 inches diameter, and consist of a pipe casting on the top of which is a bronze seat ring for the disk, which is raised about $2\frac{1}{2}$ inches, when the valve is opened, by a screw with a pilot point, operated by a wrench from above. Each valve is set in a small depression formed in the invert so that no part of the valve except the top of the screw projects above. At each blow-off is a manhole fitted with a hinged ladder, the lower part of which can be held in a horizontal position so as to serve as a platform from the end of which a man can reach the valve with a long wrench. The arrangement of manhole, valve and ladder is shown in one of the illustrations.

Where the first inverted siphon crosses the Sudbury River, however, it will be feasible to discharge large quantities of water, and so at this place two 16-inch blow-off pipes will be connected to the steel pipe now being laid and provision made for similar blow-offs from the other two pipes to be laid in the future. In the second, or Happy Hollow, siphon 10-inch blow-offs will be provided, but these will have to discharge through a pipe line 854 feet long and a ditch about 1,800 feet long, the water finally reaching the Sudbury River. The gradient of the lower portion of the aqueduct being so flat, the level of high water in the Weston Reservoir reaches nearly eight miles upstream from the channel chamber, or to a point 9,812 feet upstream from the Sudbury River siphon and just above the beginning of the 13-foot aqueduct at the railroad crossing. This condition of course complicates the problem of emptying the aqueduct.

The manholes mentioned above were placed not only at each blow-off, but also at such intermediate points as to make the distance between two manholes usually about a quarter of a mile. Each manhole has a granite coping and is provided with a steel cover locked down with one of the waterworks standard padlocks. The padlock is arranged to hang under the cover so as to be accessible to the man inside seeking to get out, but is fitted with a short chain so that it can be drawn up through a slot in the cover and unlocked from the outside. By this arrangement also the locks are less exposed. The ladder folds up out of the waterway when not in use. The lower, or hinged, part is provided with counterweights hung on "giant metal" chains, so as to move easily, and is so arranged that it can be reached and operated from either the inside or the outside.

At Station 17, on the 10-foot diameter aqueduct, and at Station 214, on the 13-foot 2-inch diameter aqueduct, are gauging manholes, to be covered with neat masonry superstructures and fitted with guide boards and other appliances for the convenient use of current meters, for making measurements of the flows in the aqueduct.

To aid in determining locations inside the aqueduct during inspection and cleaning, after the aqueduct is in service, white glazed tiles $2\frac{1}{4}$x4 inches and $\frac{1}{2}$ inch thick, with black figures and letters, are being placed in the side wall at the springing line, at every 100-foot station and wherever highways cross over or culverts are built under the aqueduct. Tiles of this description were set in the Wachusett Aqueduct and have been found satisfactory in four or five years of service.

(To be continued.)

A Four-Truss Double-Deck Railroad Bridge.—II.

The three western spans of bridge No. 1 of the Pittsburg, Fort Wayne & Chicago Railway across the Allegheny River between Pittsburg and Allegheny are duplicates, each 156 feet $\frac{1}{2}$ inch long from center to center of end pins. Each has four trusses and carries four tracks arranged the same as those of the 333-foot span which was described in The Engineering Record of October 11. The design of trusses, details of members and connections differ from those of the long span, but the floor system is the same and is continuous with that, and the specifications are the same. The loading assumed was the same except that the dead loads for the center and outside trusses were taken at 4,000 and 1,830 pounds per lineal foot respectively. The superstructure was made of open hearth steel, having a ductility so great that a punched hole $1\frac{1}{2}$ inches from the sheared edge of a plate could be drifted to a 50 per cent. greater diameter without cracking. Soft steel in the floor had an ultimate unit strength of 58,000 plus or minus 4,000 pounds. Medium steel for the rest of the superstructure had a unit strength of 66,000 plus or minus 4,000 pounds: rivet steel, 54,000 plus or minus 4,000 pounds. The minimum elastic limit was 55 per cent. of the ultimate strength. The percentage of elongation in 8 inches was required to be 1,500,000 ÷ ultimate strength. The percentage of reduction of area at the point of fracture was 2,800,000 ÷ ultimate strength. Full size test eyebars were required to break in the body; to stretch 12 per cent. in a gauged length of 10 feet; and to show a minimum ultimate strength of 62,000 pounds—9,000x(area ÷ perimeter).

All pins as well as eyebars and other forgings were annealed. Up to a diameter of 7 inches the pins were rolled and all pins were allowed 1/32-inch clearance and their holes were required to be bored within 1/32 inch of the required position. The end vertical connection flange angles for all stringers and floorbeams were fitted within 1/16 inch of exact position and then milled. All splice rivet holes in chord pieces were reamed while the pieces were bolted together in the shops in four or more sections.

The single intersection pin-connected Pratt trusses are 26 feet deep on centers and are divided into two end panels of varying lengths and five intermediate panels 22 feet $3\frac{1}{2}$ inches long. The two decks and the four trusses divide the cross section of the span into six panels, of which the upper right hand and the lower left hand ones are X-braced and the remaining ones are occupied by the tracks as in the long span, and are without transverse vertical bracing except what is afforded by the solid plate knee braces on the upper and lower sides of the ends of the upper deck floorbeams.

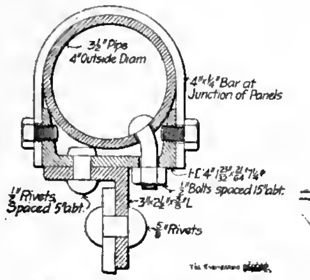
Owing to the arrangement of tracks and the clearance for trains the end elevation of the span necessarily corresponds almost precisely in general appearance with the cross section, and there are no portals or special end struts. The masonry coping is level in all cases and differences in size of expansion rockers and depth of shoes are made up by the use of grillages. In the center trusses the top chords and end posts are 40 inches wide and 26 inches deep, made with three webs throughout. The end posts have half-hole bearings on the chord pins and are locked to them with jaw plates on the outside webs. The hip joint is made on the pin center and is mitered with ½ inch clearance but all other top chord joints are made to butt and are covered, but not fully spliced, with riveted web and cover plates. In the end posts and in the other vertical posts the webs are connected at the foot and at the upper deck floorbeam by vertical transverse diaphragms. The end post has the inner flange, and the intermediate posts have both flanges, braced by intersecting lattice bars riveted together at points of contact. Horizontal connection plates are field-riveted to the feet of the intermediate posts to receive the bottom lateral diagonals.

The shoes are about 4½ feet high over all and have a 52x66-inch base plate and three webs, which give a combined length of 10 inches pin bearing. The main bearing plates have half holes, but the outside plates of the outside webs are only ½ inch thick and are extended to have full holes and lock the shoe to the similar full-hole jaw plates on the opposite sides of the corresponding webs of the end posts. The end floorbeams are riveted to the shoes through their end vertical web-stiffener angles and through the horizontal connection plates of the lower lateral diagonals which are field riveted to the bottom flanges of the floorbeams and base plates of the shoes. The expansion end shoes are seated on nests of segmental rollers with their end frames locked as described for the long span and the rollers are seated on a rack made of 13 1¼-inch thick transverse bars on a 52x1¼x78-inch base plate with a ⅛-inch sheet lead cushion between it and the cut stone pier coping.

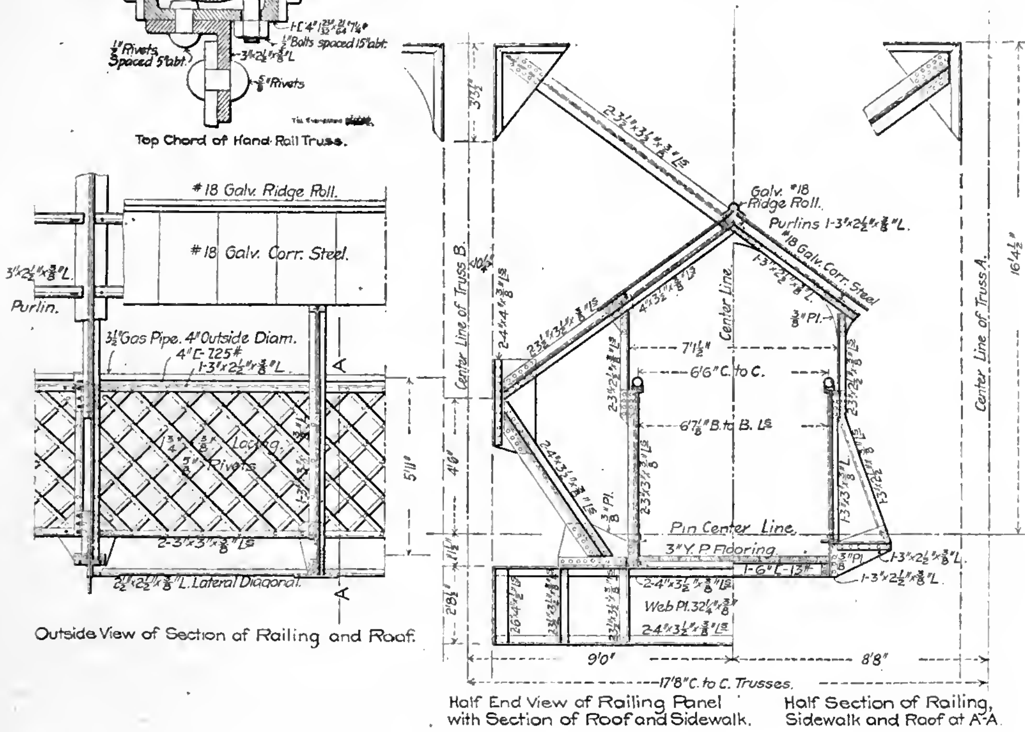
The top chord is made in three sections, the center one having a length of a little more than three panels to bring the splices beyond the pin reinforcement plates. The maximum cross section has one 40x7/16-inch cover plate, six 26x¾-inch webs, eight 6x4x¾-inch flange angles and two 5x¾-inch and one 9x¾-inch flange reinforcement plates. The hip pins are 9 inches, all the other top chord pins are 7½ inches and all the bottom chord pins are 8 inches in diameter.

The webs of the vertical posts are connected and stiffened at the floorbeam connections, by vertical diaphragms made with ⅝-inch plates and two pairs of 4x3½ and 5x3-inch angles at top and bottom respectively. The bottom diaphragm is only 33 inches long and receives the 38 field driven floorbeam connection rivets in four vertical rows. The top diaphragm is 9½ feet long and receives an equal number of floorbeam rivets and the rivets for the kneebrace brackets. All the intermediate vertical posts have two webs and four 4x4-inch angles, and have full pin holes at both ends. The main diagonals are 10-inch and the bottom chords are 8-inch eyebars, those in the end panels of the latter being stiffened by lattice bars on 3x2½-inch horizontal angles riveted to their inner faces. The trusses are cambered by making the top chord panel lengths ⅜ inch longer than the bottom chord panel lengths. The outside trusses correspond to the center ones, but are lighter and the maximum top chord section is one 32x⅝-inch cover plate, two 26x½-inch web plates, two 4x4x7/16-inch top flange and two 6x4x7/16-inch bottom flange angles and two 7x¾-inch bottom flange reinforcement flats.

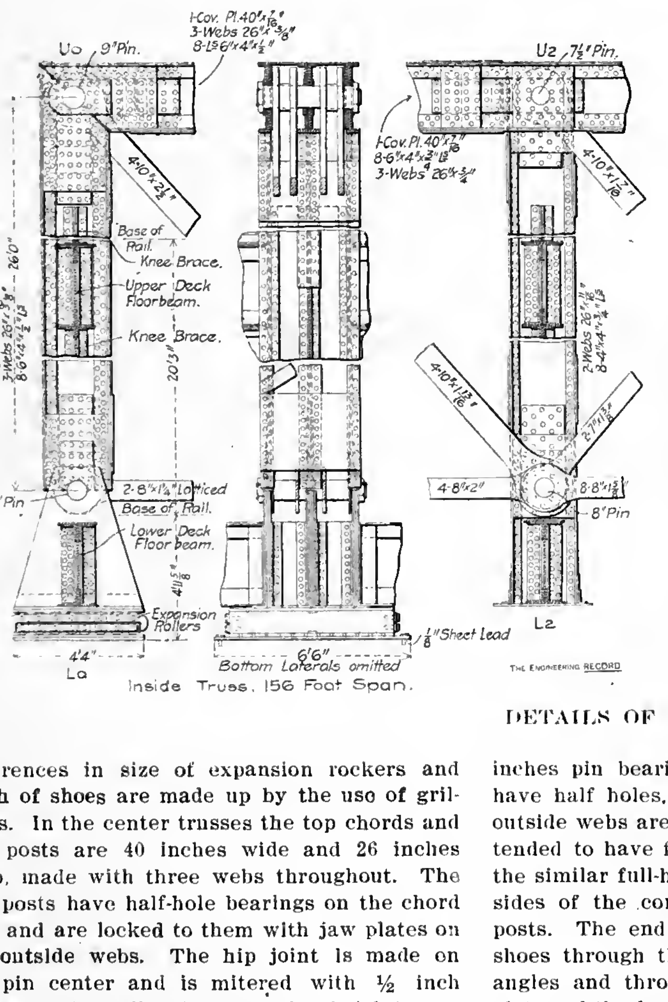
The top lateral diagonals are pairs of 3 and 4-inch flat bars with sleeve nut adjustments and eyebar heads which have 3-inch and 3½-inch vertical pins through connection plates riveted to the top flanges of the top chords and transverse lateral struts. The lower lateral diagonals are single 6x⅜-inch flat bars field-riveted to horizontal connection plates on the bottoms of the vertical posts and to the bottom flanges of the stringers at their intersections.



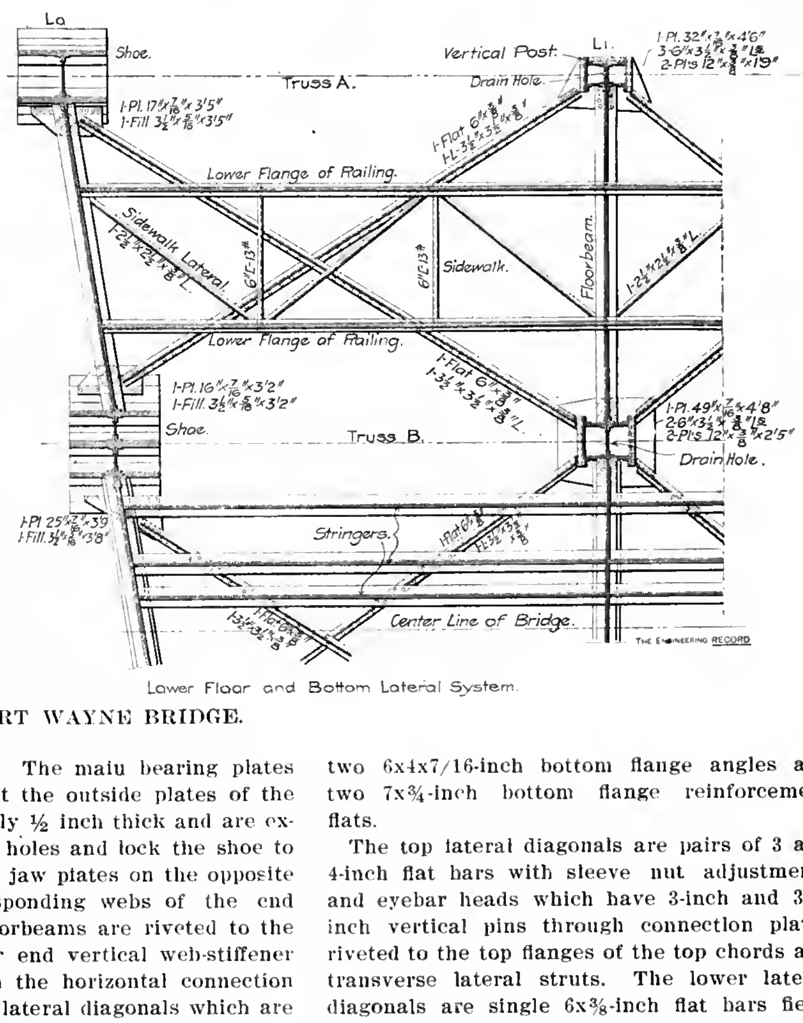
Top Chord of Hand-Rail Truss.



Foot Bridge and Shelter.



Inside Truss, 156 Foot Span.



Lower Floor and Bottom Lateral System.

DETAILS OF FORT WAYNE BRIDGE.

They are stiffened against flexure under their own weight by single 3½x3½x⅜-inch angles riveted to the upper side between stringers and at the ends, and they form three panels of X-bracing between every pair of floorbeams. At the ends of the span they are field riveted to horizontal connection plates shop-riveted to the base-plate of the shoe and field riveted to the floorbeam bottom flange.

As in the previously described 333-foot span of the same bridge the vertical transverse panels between trusses A and B, below the upper floorbeams and between trusses C and D above the upper floorbeams are occupied with sway brace diagonals. In both cases these are pairs of angles riveted together back to back to form Ts which have their wide flanges in the same plane and are riveted together at intersections. In both cases also they form simple X-braces, and above the upper deck their extremities extend to the ends of the transverse struts. Below the upper deck the bracing is modified by connecting the lower ends of the diagonals to the vertical posts at the tops of the kneebraces, about 6 feet above the top flanges of the floorbeams so as to raise the intersection of the diagonals and give clearance under their lower ends for a footwalk in the center of the panel. The footwalk is supplied with deep lattice-girder hand rails which carry its floor between panel points of the main truss, and it has a double pitched roof to protect it from drippings from the railroad track overhead. The top flange of the hand rail girder consists of a small channel, an angle and a 4-inch pipe fastened together as shown in the detail, the oval bottom heads of the bolts being inserted through slotted holes in the pipe and turned 90 degrees before their nuts were screwed up.

Each span weighs about 650 tons and was designed and constructed under direction of Mr. Thomas Rodd, chief engineer and Mr. J. C. Bland, engineer of bridges for the Pennsylvania Lines West of Pittsburg. The inspection was performed by the railroad company's force under Mr. C. P. Buchanan, inspector of bridges. It was built at the Keystone plant of the American Bridge Co., Mr. Richard Khuen, engineer. It was erected under direction of Mr. S. P. Mitchell, chief engineer, and Mr. H. A. Green, assistant engineer and superintendent of erection for the western district.

Cross-Section at Center of 156 Foot Span.

The Water-Works of the Louisiana Purchase Exposition, designed by Mr. Richard H. Phillips, will have 15½ miles of cast-iron pipe 4 to 24 inches in diameter, 19¾ miles of ¾ to 6-inch wrought-iron pipe, 375 hydrants and 843 gate valves. The pipes will be run along the roofs of many of the buildings as well as underground. A novel feature will be the deck turret revolving standpipes in the buildings on platforms about 30 feet above the floor. When the ordinary fire streams are insufficient, these turrets will throw 3-inch streams under 150 pounds pressure, the direction being controlled by tiller wheels. Of course these powerful streams will wreck the exhibits they strike, but they will only be employed when the loss of a few exhibitors is needed to ensure the safety of many. Water will be drawn from an 8,000,000-gallon impounding reservoir by nine pumps, and there will be an emergency connection with the city mains.

Gravel Roads in Grand Rapids, Mich., according to City Engineer L. W. Anderson, are constructed so as to reduce the voids to a minimum, by using a mixture of fine gravel when necessary. The clay used in the body of the gravel has been reduced by this means to the smallest permissible amount. When giving the final rolling, an additional sprinkle of clay is added to prevent the gravel from raveling during the dry summer months.

The Use of Wood Pavements Under Heavy Traffic.

Abstract of a paper presented to the American Society of Municipal Improvements by F. A. Kummer.

Attention was drawn in the first part of the paper to a paving block exhibited in connection with it, which was removed from Tremont Street, Boston, after being in use nearly two years. It was taken from near the center of the street where the traffic is very heavy. The surface of this block was almost as hard as stone and the reduction in depth was very slight, being at the most not over ⅛ inch in two years. This reduction in depth was not due to wear, but to the compression of the upper fibers of the block under heavy travel, so that it is considered quite certain no corresponding reduction in depth will be apparent during succeeding years. Under the action of the traffic, the sand spread over the surface of this street was driven into the outer fibers of the wood, so that the whole wearing surface was compacted into a tough and absolutely impervious surface. The edges of the block have not rounded off any, due to the fact that the blocks are laid as close together as they can be driven, thereby leaving no point of attack, as is the case with granite or other block pavements laid with wide joints. When dry, wood pavements are not as slippery as, for instance, asphalt pavements, owing to the fact that the upper surface of the wood always retains a certain elasticity, which is not found with other forms of pavements. When the two pavements are covered with frost, sleet or slime, there is perhaps little to choose between them on the grounds of slipperiness on heavy grades, but for streets of this class a form of pavement has been developed which consists of a block laid with a grooved joint, which proves a perfect foothold for horses upon grades, and as so laid in the City of Boston, has been absolutely non-slippery.

In considering the general question of the paving of streets, several forms of pavement seem open to selection, namely, granite block, wood, asphalt, vitrified brick, asphalt block, bituminous macadam and ordinary macadam. Of these pavements, only the first three named have any place under very heavy traffic and it is questionable whether asphalt, unless laid with much greater care than is usually the case, should be included. For streets of the very heaviest travel, such travel even as is found on the streets in London, such as the Strand, Fleet Street and others too numerous to mention, wood is the most economical and satisfactory pavement that it is possible to lay. Experience has shown abroad that this is true, and streets such as those named have travel which is far heavier than is to be found upon any street in this country, although it is probable that on some of our streets the concentration of the loads is greater owing to the presence of street car tracks in the roadway. If we exclude asphalt as a suitable pavement for streets of this class, we have left only granite block and wood from which to choose.

Granted that it is possible to so prepare wood that it does not absorb moisture and is proof against decay, let us consider how such a block of wood can be destroyed by the action of traffic. If the practice were followed of laying the blocks with one-quarter or one-half inch joints, as is the case abroad, the exposed edges of the blocks would undoubtedly wear with more or less rapidity under the action of the shoes of horses. This wear is not as great in the case of wood as one might at first suppose, as has been demonstrated by the Boylston Street pavement in Boston, to which reference has already been made; but by laying the blocks on streets which are level or nearly level with no joints between them whatever; in other words, by driving them together so closely that their surface under travel presently becomes unified, presenting no joints or cracks, a smooth surface results which has no vulnerable point at which it can be attacked by the action of traffic. The calks of horses' shoes cannot chip off the surface of the pavement, as is the case with brick or even stone, nor can the fibers of the wood be ripped off because they are vertical, and resemble in this respect a bundle of fine wires set on end and tightly wedged together. We have found that the action of traffic on such a block is to drive the upper ends of the fibers down and compress them, so that the heavier the traffic, the more solid becomes the surface of the block, just as would result from the continual pounding with a hammer upon the end of a stick of timber. This felting action, as it perhaps might be termed, upon the fibers of the upper surface of the block, is assisted by the resinous material forced into the wood along with the creosote oil, for which reason we have never found a case of brooming in the upper surface of the block as is found with the timber as treated abroad, and especially when laid with an open joint. The whole theory of the vertical fibers in the block is that they should be tightly bound together so that each supports its neighbor, and for this reason the faces of the block should not be separated by a joint, if it can be avoided, as otherwise the blocks cannot mutually support each other. It is interesting to note that a recent copy of the "Sanitary Record" in London stated that the practice of laying wood blocks with a tight joint was rapidly coming into favor in London owing to the greater durability which it gave to the pavement. In the case of the grooved block used on Boylston Street, the groove between the blocks was one inch deep and the same results would have been secured had the groove been only one-half inch deep. This small groove would leave almost the entire two faces of the block bearing against each other and supporting each other solidly in the street.

Owing to the fact that the wood selected for treatment is all heart wood, there is very little difference, if any, in density in the individual block. What difference does exist is largely made up by the greater absorption of the preservative fluid by the more porous blocks and the corresponding less absorption by the denser blocks. This may seem a finely drawn theory, but yet the fact remains that over two years of heavy traffic on Tremont Street has failed to demonstrate the slightest irregularity in the wear of individual blocks. This is the only way in which such a pavement could wear out; that is, by wearing in spots which would result in holes in the pavement. So long as the wear is even over the entire surface of the pavement, its life is almost indefinite. It is interesting to note that the stretch of wood pavement laid in front of the Auditorium Hotel in Chicago, which is now in its fourth year, has shown exactly the same results as those recited above for Tremont Street.

In the foreign pavements far less care is taken in the selection of the wood and a large majority of the blocks laid have a considerable proportion of sap wood in them; this wood, being extremely porous and much softer than the harder blocks, does produce a certain irregularity of wear in the pavement. The four vital points of difference between the London pavements and those laid in Boston are: First, the far greater hardness of Georgia pine as compared with Swedish deal. Second, the treatment of the timber with 22 pounds of a mixture of creosote and resin as against 10 pounds of straight creosote oil generally used abroad. Third, the selection of all heart wood and the exclusion of all sap wood, a practice not followed abroad. Fourth, the laying of the blocks with a tight joint.

In these four respects we believe we have vastly improved upon the foreign practice, yet under a traffic of over 40,000 teams per day, the life of wood pavement on the Strand in London is given in official reports as seven years. Very few, if any, granite pavements would be in condition for travel at the end of that time under that traffic. It is therefore, first, the splendid showing of the pavements as laid abroad, and, second, the improvements made over the foreign practice, which causes us to say that properly constructed wood pavements have a longer serviceable life than granite.

An International Committee on Street Hygiene.

The International Congress for Hygiene and Demography, which convened in Paris in August, 1900, appointed an International Committee of Street Hygiene, composed of men prominently connected with municipal improvement on the continent of Europe, in England and America, Mr. Rudolph Hering, of New York, being the member from the United States. This committee met in September last and voted to prepare recommendations to be submitted to the next Congress of Hygiene and Demography, to be held in Brussels in 1903.

The purpose of the International Committee of Street Hygiene is to further that branch of sanitary science which deals particularly with the following subjects: Construction and maintenance of the surface of roads and streets; cleaning of streets, including removal of snow and collection, removal and disposal of sweepings; planting of trees and plants; public sanitary conveniences; storage, collection, removal and disposal of house refuse and refuse from mills, markets and slaughter houses. In general the committee recommends that public work of this character should be done by the public authorities under one administrative officer, who should be directly responsible to the authorities and who should be a trained engineer well acquainted with hygiene.

The cleaning of streets should be so conducted that neither the atmosphere nor persons nor objects will be polluted, and the raising of dust should be prevented by systematic watering. All public ways should be cleaned at least once a week and main thoroughfares two or three times a week or every day, the best time for the work being the night or early morning. Street sweepings should be removed immediately after their collection, without intermediate storage, in tight carts, which should be kept thoroughly clean. The use of street sweepings for filling lowlands, especially in the neighborhood of houses, should not be allowed if the sweepings contain much organic matter. All kinds of house refuse and refuse from markets and slaughter houses should be regarded as dangerous to health. Any handling of house refuse should be avoided, as far as possible, and the sorting of such refuse should be prohibited. In the houses the refuse should be put only into metal receptacles of convenient shape and size, which can be readily handled and thoroughly cleaned. Wherever possible, these receptacles should be collected or emptied every day, preferably during the night or the early morning hours before traffic in the streets commences. Destruction by fire is regarded as the most satisfactory method, and the tipping of such refuse into waste places, for filling, in the neighborhood of houses is so objectionable that it should always be prohibited. Dumping the refuse into a water-way, as is sometimes done, generally creates a nuisance.

The Mechanical Plant of the Prudential Buildings, Newark, N. J.

One of the most elaborate mechanical plants yet provided for meeting the requirements of the modern office building has been supplied for the group of four large office structures in Newark, N. J., belonging to the Prudential Insurance Company of America. The plant is a complete one in the variety and character of its equipment and possesses a number of features unusual in this class of work. It has been accorded valuable space in one of the buildings, and being readily accessible to visitors, not a little attention has been paid toward improving its general appearance.

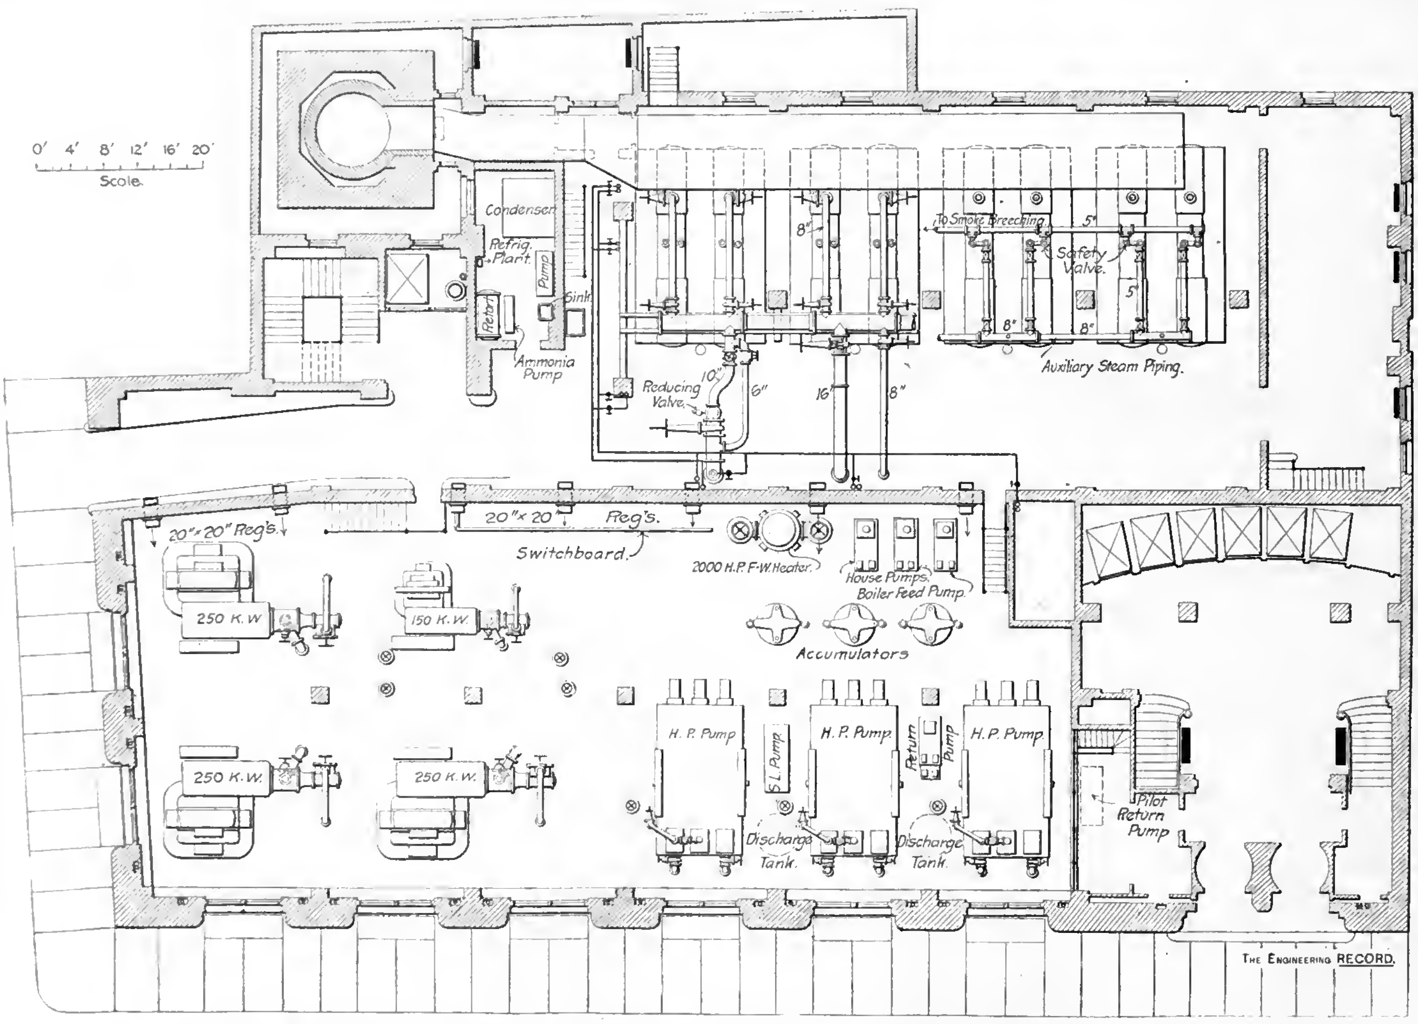
The four buildings are all twelve stories high and in the aggregate have approximately 13 acres of floor space. Three of the buildings and a large addition to an old building are new and in one of the new buildings, known as the North Building, is located the mechanical plant. The new plant supersedes that formerly serving the old building and is connected to all the buildings by means of tunnels under the separating streets. The chief requirements met by the new installation are lighting, heating, elevator service and a hot, cold and refrigerated water supply. Lighting is, as usual, by incandescent electric lamps, of which there are probably 15,000 all told, of 16 candle-power each on 110-volt circuits. Heating is largely by direct low-pressure steam radiation, supplied with exhaust steam ordinarily and with live steam when necessary. The elevators are all of the hydraulic type, supplied from the central plant with water at unusually high pressure. There are in all the buildings 27 passenger elevators and including book lifts and dumb waiters 36 hydraulic elevator units connected to this system. The water supply, that is, the plumbing service, is quite elaborate and has already been described in The Engineering Record of July 6, 1901.

The mechanical plant occupies all of the ground floor of the North Building except that required for the main entrance hall to the elevators and stairways for the office floors above. It consists of an engine room, which is in the building proper, and a boiler house, which is practically an addition on the rear side. The floor of the engine room is some distance below street level, and the room extends to the ground story ceiling. It is thus a lofty room and in addition has high windows on two street sides affording the public in the street a splendid view of all the machinery. To favor further the chance to make the plant an exhibition one, all piping, so far as possible, is carried in a cellar underneath the engine-room floor. The engine room is about 45x111 feet in plan and contains four electric generating sets, the pumping equipment and apparatus for the elevator installation, a number of other pumps, a feed-water heater and an elaborate switchboard facing the street windows. Vaults have been built under the sidewalks and this space has been largely utilized for a storage battery operated in connection with the electric plant. The engine room is served by two 8-ton hand-power traveling cranes of 22-feet span built by Reading Crane & Hoist Works.

The boiler plant, which is located in a room 45x79 feet in plan, is unique so far as being related to a power plant for an office building. It is provided with coal and ash handling machinery and a large overhead storage hopper or bin, allowing a gravity flow of coal to the firing space. Below the firing floor there is a cellar containing boiler-feed pumps, a number of tanks and the conveyors for hauling coal and ashes. In the boiler house, in addition, there is an elaborate ventilation plant and a refrigerating plant for furnishing iced water.

There are eight boilers in all, of 250 horsepower capacity, set in four batteries, with space for a fifth battery. They were built by The Babcock & Wilcox Company and are of wrought-steel construction of the following dimensions: Each boiler is 9 sections of tubes in width, each section having twelve 4-inch tubes 18 feet long. The steam drums are 42 inches in diameter and 23 feet 4 inches long, made of ½-inch plate. Each boiler has 2,217 square feet of heating surface and 39.1 square feet of grate surface, a ratio of 56.7 to 1. The boiler plant is served by a masonry double-shell chimney, rising clear of the building as an octagonal shaft of Indiana limestone, surmounted by a heavy carved stone capital. This structure, which was described in detail in The Engineering Record of December 14, 1901, has a total height of 230 feet 9 inches, but its top is conveyor, the former delivering coal received at the street to the latter and the bucket conveyor carrying the coal overhead to the bin, this conveyor, as is frequently done, being used also to carry the ashes, dumping them into an ash bin from which they are loaded from a spout into ash carts, as desired. Coal, as delivered through a coal hole in the sidewalk, falls into a weighing hopper. This is emptied upon the belt conveyor which travels in the cellar of the building to the nearest corner of the boiler house cellar. The belt, which was furnished by the Webster Manufacturing Company, is 16 inches wide and is driven by a 2-foot pulley from a 7½ horse-power C & C electric motor. At 70 revolutions per minute the belt speed would thus be 440 feet per minute. The belt is enclosed its entire length by a box of No. 10 sheet metal to prevent the dust flying all about, and at its discharging end, after it dumps through a chute upon the bucket conveyor, it is located a chute through which the ashes are dumped from the conveyor to an ash hopper. Ash carts are backed in a driveway underneath this and there filled. The movable dump carriage can be controlled by chains from the boiler-room floor. The coal bin is of the V-shaped class and its sides, which are of brick arches sprung between longitudinal I beams, are pitched about 23 degrees. Its total capacity is about 750 tons. In this connection mention should be made of the fact that the boiler room below the bin is ventilated, as indicated in the cross-section drawing herewith, the air at the inner wall of the boiler house having to pass through louver openings in a monitor built against the adjoining building wall.

There are two steam headers, each supplied by independent connections from each of the boilers. One, 20 inches in diameter, collects the steam for the electric generating units and the other, 8 inches in diameter, receives steam



THE MECHANICAL PLANT FOR THE PRUDENTIAL BUILDINGS, NEWARK, N. J.
George B. Post, Architect.

210 feet above the level of the grates; it has a constant inside diameter of 9 feet.

The smoke breeching connecting boilers and stack is of No. 8 black iron, suspended across the rear of the boilers and of the same cross-section throughout, changing in shape at the stack to enter the necessarily narrow and long inlet to that point. This cross-sectional area is about 25 per cent. greater than the full area of the chimney. The aggregate area of the individual smoke passages from the boilers to the breeching is practically that of the main breeching. For non-conducting covering magnesia blocks 1½ inches thick fastened to wire mesh placed to enclose 2 inches of air space were used, with ½ inch of magnesia plaster and ½ inch of hard finish plaster painted two coats of waterproof paint on top of the blocks.

The coal and ash handling machinery comprises a belt conveyor and a chain and bucket cleaned by means of a wire brush rotated against it. The dust liable to cling to it is in that way not allowed to accumulate and cause trouble. The conveyor hauls the coal upward at an angle of about 5½ degrees with the horizontal.

The bucket conveyor is of the McCaslin type and travels in the usual way, along the cellar floor underneath the ash hoppers below each boiler ashpit, then up one end of the building, then across overhead the length of the coal bin and down at the other end of the building. It runs through a monitor to the roof above the bin, which thus affords sufficient light to inspect readily the distribution of coal throughout the hopper, and at one end of the monitor is located the drive, which requires a 10-horse-power electric motor. The usual tripping or dump carriage is provided, and at the opposite end of the monitor from the driving motor is for the various pumps, this header being provided in the boiler by a cross-connection with the larger header and joined in the cellar under the engine room with a main from the larger header, so that the pumps of the elevator installation can obtain steam from either source. The steam piping in the boiler room is shown in the accompanying drawings. An 8-inch pipe feeds the 20-inch header from each boiler, with a valve both at the steam drum and at the header. From the header are taken a 16-inch main for the electric generating sets, a 10-inch connection for supplying the heating system through pressure reducing valves, when live steam is necessary, and an 8-inch pipe joining main header with the auxiliary or pump system of steam mains. For the auxiliary header, the safety-valve outlet from each boiler is fitted with a Y fitting, and to one branch of this is attached the safety valve and to the other a 5-

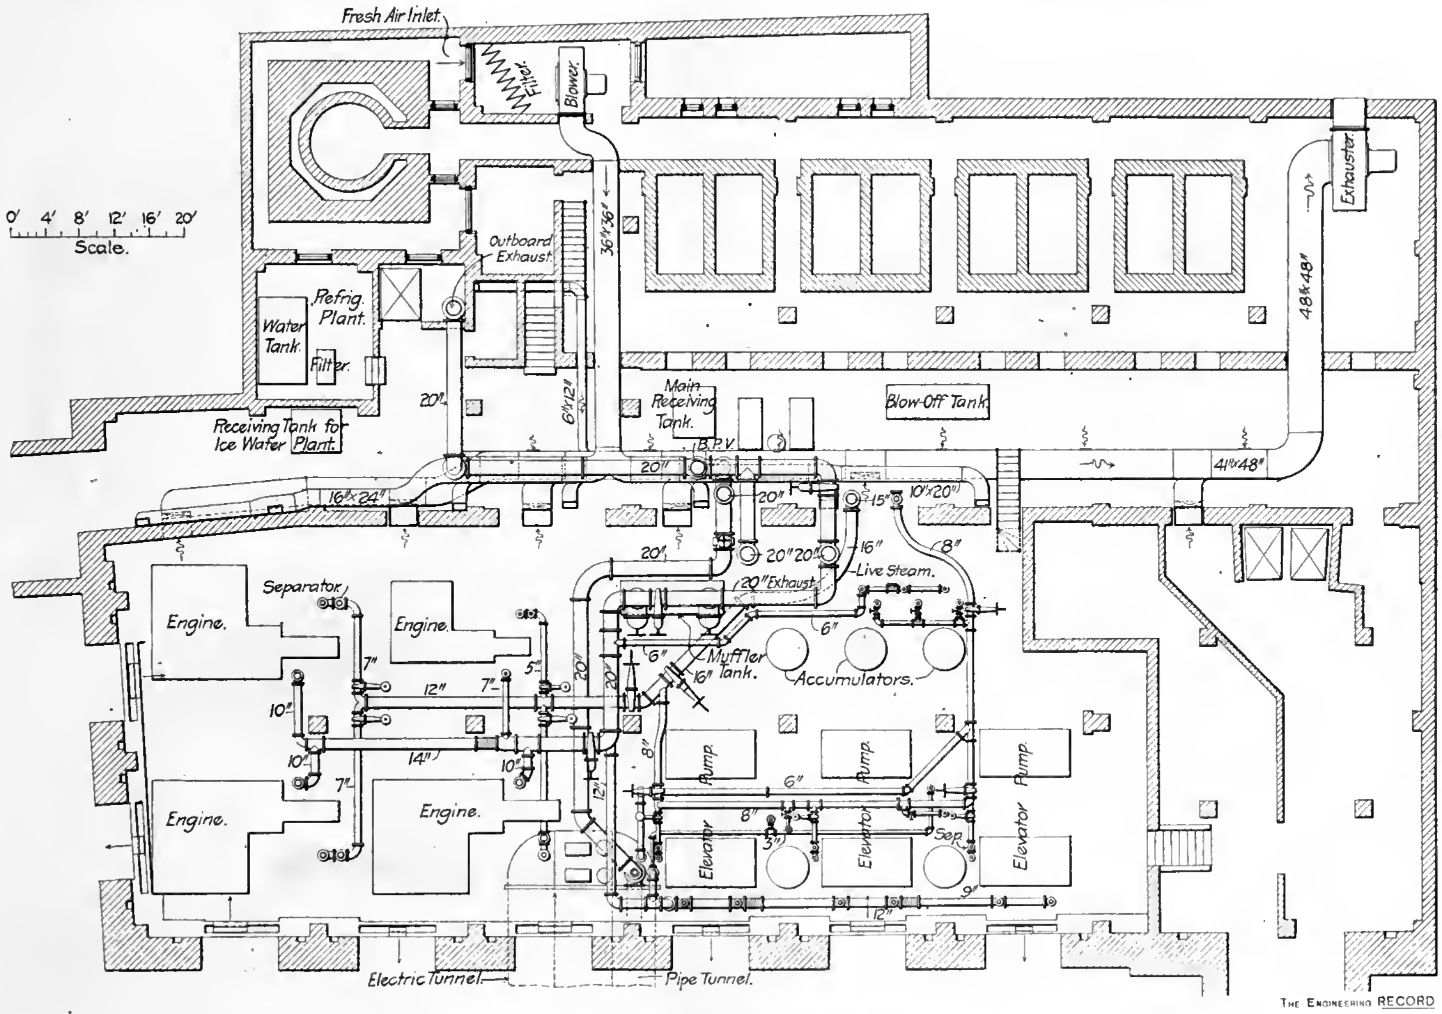
inch connection to the auxiliary header, two valves also fitted in the auxiliary header feeders. The safety-valves all have exhaust or discharge pipes for the blow-off steam and these all connect into a discharge main which is carried into the smoke breeching close to the stack.

The working pressure is 150 pounds per square inch and the steam piping was tested to stand 250 pounds hydrostatic pressure. The pipe bends from boilers to headers, the high-pressure mains from the headers and the branch pipes to the engines and pumps are all of wrought iron, with valves and fittings designed according to the Walworth Manufacturing Company standard for 250 pounds pressure. The flanges have a plain face with a raised surface for gaskets and are spot faced for bolts. For high-pressure pipes 6 inches in diameter and larger, the Van Stone joint is used, as it is also for low-pressure work 7 inches and over. For the elbows below the floor. The 16-inch outside diameter pipe in the boiler room is dropped from the main header to the cellar, as shown, and subdivides into a 15-inch outside-diameter main for the electric generating units and into an 8-inch pipe which is connected into the 8-inch pipe carried from the auxiliary header into the cellar. At this cross connection are tapped the steam supply pipes to the elevator pumps. The steam connections to all the engines and the main elevator pumps are provided with De Rycke steam separators in the cellar and in addition to the throttle valve have bevel-geared valves near the supply mains in the cellar operated from floor stands in the engine room. The sizes of the pipes would indicate, in the case of the boiler supplies, at the normal rating of the boilers, a velocity of steam flow of 1,100 feet per minute and in the case of the engines at rated load and fair steam consumption about 1,600 feet per minute.

pressure and consequently smaller pipes to the different buildings are possible. With this high pressure, instead of the pressure tank usual with lower pressure systems, accumulators are used. These weighed tanks rise through cellar into the engine room. For the satisfactory operation of the valves to the elevator cylinders, a low-pressure hydraulic system has been installed, for which purposes the pilot return pumps have been provided maintaining a pressure of 80 pounds.

Between the three accumulators and the partition wall are three 10x6x10-inch Laidlaw-Dunn-Gordon duplex pumps, two for house and fire service and the third, with outside packed plunger, for boiler feeding. A Berryman steam-tube feed-water heater, containing 1,660 lineal feet of 2-inch seamless-drawn brass tubing, is also located in the engine room. It is 58 inches in diameter and has a height of 17 feet.

The exhaust steam from the engines is collected into an 18-inch main and that from the elevator pumps into a 12-inch main, and the two unite into a 20-inch main, as shown in the plan of the cellar below the engine room. To provide for expansion in these lines Wainwright expansion joints are employed. The exhaust first passes through a tank 12 feet long and 4 feet in diameter, which is a Utility combined grease extractor and muffler tank. It is constructed of a ⅜-inch steel shell and ½-inch heads and is provided with a by-pass for the steam, if it is desired to cut it out temporarily. The exhaust main next reaches the connection to the feed-water heater, about which it has a by-pass in the cellar. From this point the steam may pass into the heating system for the buildings or into the atmosphere, the latter pipe fitted with the usual back-pressure valve. Here, as shown, is the auxiliary live-steam supply to the heating system; this is a 20-inch pipe dropping from the boiler room, starting as a 10-inch



CELLAR PLAN OF THE PLANT, SHOWING STEAM PIPING AND VENTILATION.

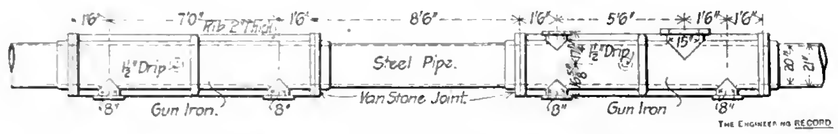
other high-pressure pipes extra heavy screwed joints are used, with the pipe flush with the flange after the latter was faced off in a lathe. The gaskets are of corrugated copper. The steam headers are made up of cast gun-iron headers, with which the connections to and from the headers are made, and of steel pipes with the Van Stone joint, the gun-iron headers being opposite each pair of boilers and the steel pipes connecting the gun-iron parts. The gun-iron headers are built with heavy ribs, of iron of 30,000 pounds tensile strength and with flanges drilled for the Walworth 250-pound standard. The steam headers are supported from heavy brackets, the 20-inch header on roller chairs to allow for expansion.

The machinery in the engine room is, in general, supplied by wrought-iron bends rising through the floor and turning downward to the steam cylinders, all of sufficient length to eliminate flanged joints between throttle and

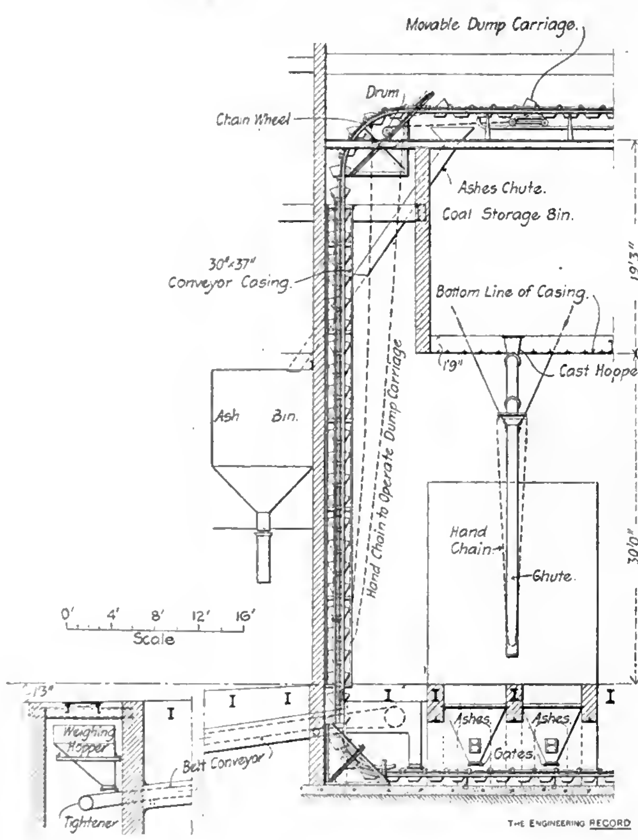
The electric generating units are located at one end of the engine room and consist of Ball & Wood non-condensing tandem-compound engines direct connected to Bullock 125-volt direct-current dynamos. Three of the units are of 250 kilowatts capacity each, and the engines are 17 and 30x18 inches in cylinder dimensions; the fourth is of 150 kilowatts capacity with a 12 and 22x16-inch engine.

The elevator equipment includes three compound three-cylinder Laidlaw-Dunn-Gordon pumps, the three cylinders located side by side and driving three water plungers, a safe-lifting pump and two pilot return pumps. The large pumps have one 17-inch steam cylinder and two 19-inch steam cylinders, 5-inch water plungers and a 24-inch common stroke. For regular service a pressure of 750 to 800 pounds is maintained by the pumps, with perhaps an average of 720 pounds at the elevators so that the volume of water necessary is less than with a lower pipe from the main steam header and fitted with two Kieley reducing valves arranged in series to reduce from 150 to 80 pounds and from 80 to 0 pound. The heating main continues 20 inches in diameter through the cellar to the tunnel to the West Building, supplying on the way a 10-inch main for the North Building and the North West Building.

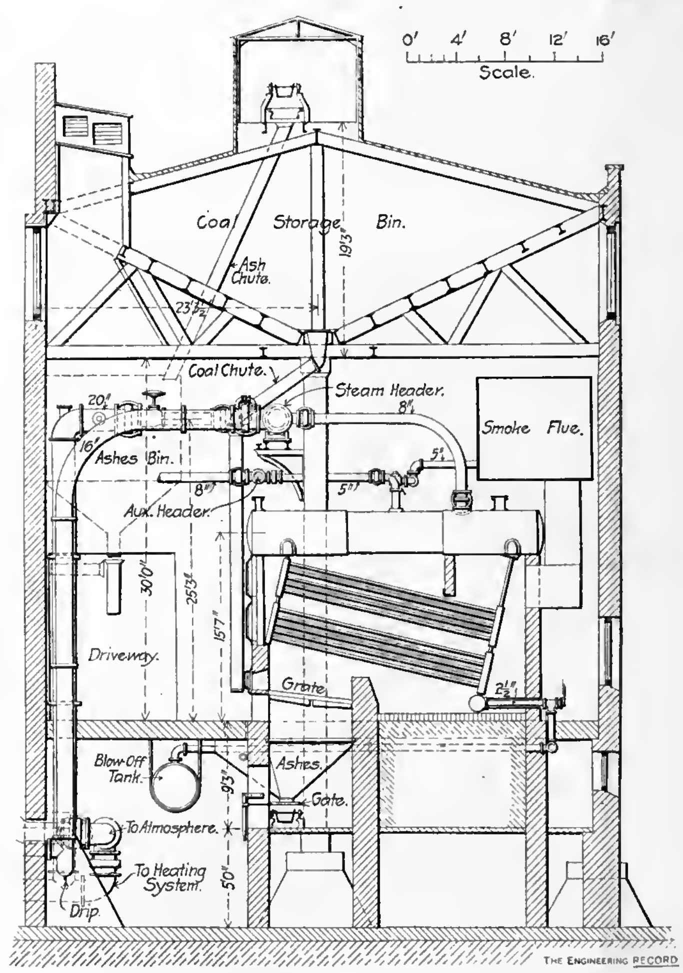
A section of the tunnel connecting the North and West Buildings is given in the accompanying drawings. It is built in duplicate, there being two tunnels parallel with each other, about 6 or 7 feet apart, the two tunnels united at each end, and one given up to the steam and other piping, as indicated, and the other to electric cables and wires. The construction is fully shown. The tunnels are 75 feet long and their floors are about 21 feet below street level. The steam pipes are supported, as shown, on wrought-iron pipe standards adjustable as regards height; besides the heating main there is a high-pressure main and the corresponding exhaust main. The heating main is graded slightly in the direction of steam flow and at convenient points suitable drain connections are provided. To receive the drip water, from piping in cellar and tunnel, 18-inch tanks 5 feet long are located at the power-plant end of the tunnel, one to collect high-pressure drips, another, the low-pressure drips, and the third the drips of the plumbing system. Each tank is served by a 4½x2¾x4-inch duplex steam pump under the control of a pump governor, one delivering the high-pressure drips to the main receiving tank, while the low-pressure drips, containing grease laden water from the exhaust main, is discharged into the blow-off tank. The heating return main, not shown in the cross-section drawing of the tunnel, is 4 inches in diameter and passes through the cellar of the plant to the main receiving tank, which is located against the boiler-room cellar wall.



THE CONSTRUCTION OF THE STEAM HEADER.



COAL AND ASH HANDLING.



CROSS-SECTION OF THE BOILER HOUSE.

All the condensation from the heating systems of the buildings is returned to the main receiving tank, which is 5x6x6 feet in size, this water being supplemented as may be necessary by water from the receiving tank of the refrigerating plant. This tank is of the same size as the main receiving tank and takes the overflow of the condenser of the refrigerating apparatus. Near the main tank are two boiler feed pumps of the same size and type as the boiler feed pump in the engine room, the latter pump being a reserve which is connected for house or fire service as well. The pumps discharge through a feed-water filter and the feed-water heater in turn before delivering to the boilers. The filter is a Ward combination zinc box and filter composed of 10 cast-iron 18-inch cylinders 7 feet high.

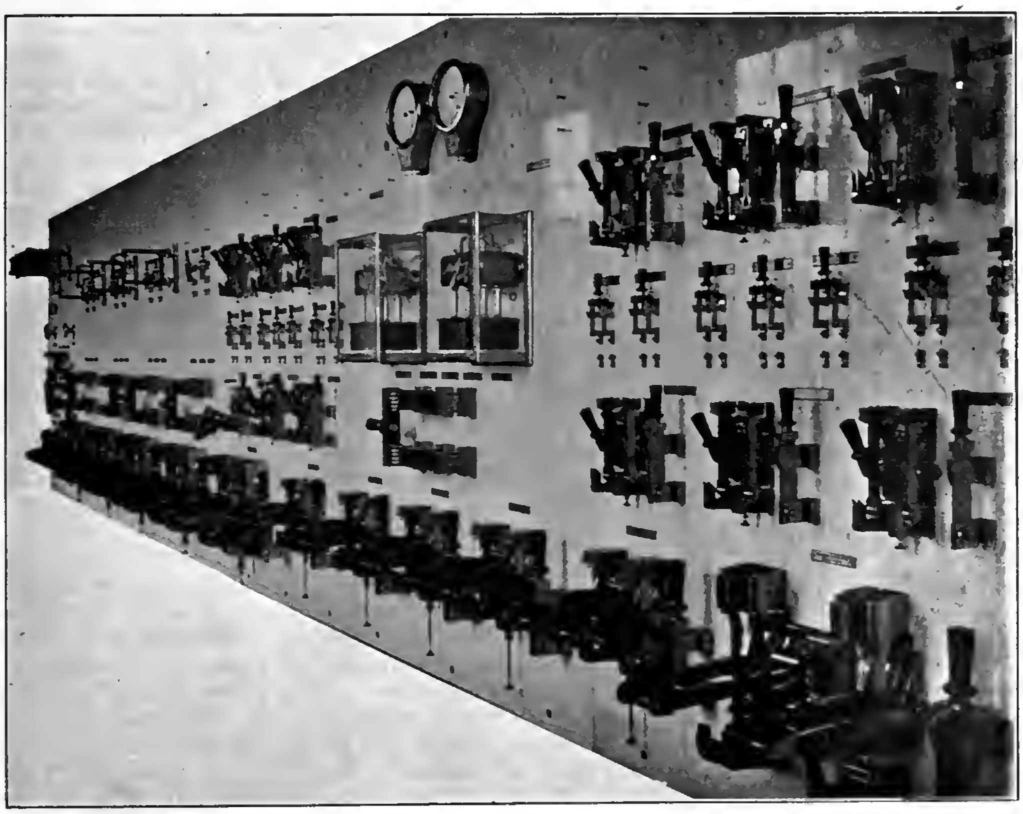
The feed piping is of brass, 4 inches in diameter, and the main extends under the boiler floor with 1½-inch brass connections rising through the floor to the boilers. Each riser has a 1½-inch inlet for an injector connection, a Nathan injector being supplied to each boiler. Valves, fittings, flanges, etc., of the feed piping are of cast bronze. The blow-off tank located, as shown, is 4 feet in diameter and 12 feet long, constructed of ⅝-inch steel with 7/16-inch heads. The contents of the tank have to be cooled before discharge into the sewer, and such fresh water as may be required for the plant is passed as usual through a submerged coil within the tank. There are ten of these, of 2-inch seamless brass, with their ends connected to two cast bronze headers with 5-inch water connections. There are all told about 230 lineal feet in the brass coils.

For ventilation the plant is unusually well equipped, having both a plenum and an exhaust fan. The air supply is not heated at all, as, of course, the circulation of air is intended largely to maintain as low a temperature as possible, particularly in the pipe cellar. The fresh air is blown into the engine room and exhausted from the cellar, the air to the cellar, however, coming partly from the engine room through manholes in the floor, but chiefly from out of doors. The plenum fan is located at a rear corner of the boiler-house cellar and draws through a cheese-cloth screen consisting of 15 leaves, each 6½ feet high and 2 feet wide, giving a total dust filtering area of 195 square feet. The fan is placed immediately within the filter and is of the single inlet type with a 72-inch centrifugal blast wheel in a full housing. It is of the B. F. Sturtevant manufacture and is direct-connected to a 15-horse-power **C & C** electric motor arranged to run at 200 to 300 revolutions per minute. Assuming that it delivers 25,000 cubic feet of air, the velocity through the filter will be about 2 feet per second. As shown in the cellar plan, the air is discharged through a duct 3 feet square, which delivers to seven vertical flues running to openings in the engine room, these 12 feet above the floor. The velocities of air on the assumed fan capacity figure 2,750 feet per minute in the ducts and 2,550 feet in the flues. The registers in the engine room, which are twice the area of the flues, are provided with copper swivel discharge outlets, directing the air downward, horizontally or upward, as desired.

The exhaust of the air is accomplished in an interesting manner. Vertical flues are built in the outside walls of the building receiving outside air a short distance above street level and discharging it, some flues into the pipe cellar, others into the vault. The air is drawn through the cellar to vent openings in the inside wall of the cellar, where it is exhausted through a duct and discharged through a vertical shaft into the atmosphere by means of the exhaust fan. This is a Sturtevant centrifugal fan, of 7-foot wheel, direct connected to a 20-horse-power motor. When running between 170 and 240 revolutions per minute, it is depended on to exhaust 60 to 80 per cent. more air than blown in by the plenum fan, so that there may always be an inflow through all sorts of openings into both the engine room and the cellar. It should be stated that the vault, which contains the storage battery, has a separate exhaust to the atmosphere, lead lined to resist the action of the acid fumes from the storage battery. The fresh-air supply ducts are covered with 1-inch magnesia blocks wrapped in canvas.

Returning to the engine room, and the electric equipment, the switchboard consists of nine panels of marble, 7½ feet high, 36 feet in total length. Eight of the panels are devoted to the instruments controlling the electrical output, while the ninth contains instruments pertaining to the steam plant, eight steam gauges corresponding to the eight boilers, a low-pressure steam gauge, a vacuum gauge and a recording steam gauge. Of the electric panels of the board, the first has the instruments for the storage battery control, the next four correspond to the four electric generating sets and the remaining three are given up to the various feeders. The board stands 5 feet from the wall.

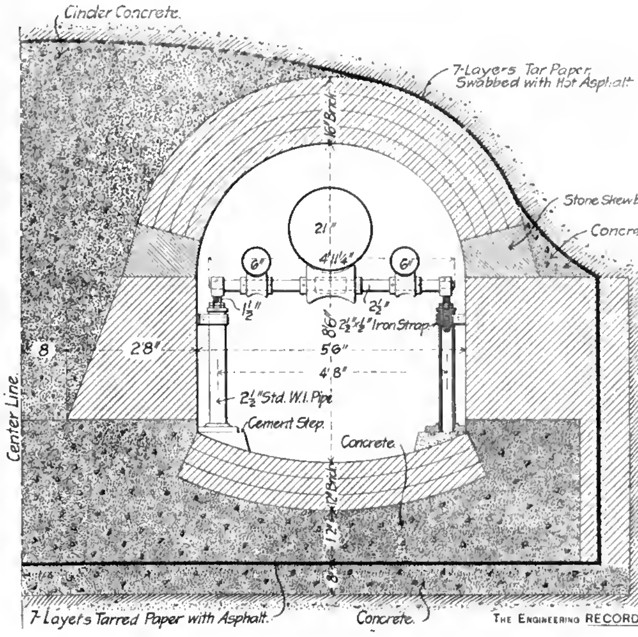
The storage battery is located in the vault under the sidewalk and is used for nights or at times when but few lamps are required. It is of 800 ampere-hours capacity and includes 15 end-cells with a motor-driven end-cell switch which can be controlled from the switchboard. A Crocker-Wheeler motor-driven generator, in the engine room, is used as a booster in charging. For the control of the battery, the usual instruments are provided, including a two-pole double-throw switch for charging in the one case and discharging in the other and a similar switch for connecting the battery on either the light or power busses. Circuit breakers are provided and an automatic overload switch, together with a wattmeter, a voltmeter and an ammeter, the latter two mounted on brackets.



Switchboard before Indicating Instruments were in Place.

An elaborate electric bell installation is installed, supplied from small motor-generators for lowering the voltage.

Each of the generator panels has a two-pole double throw main switch, so that its dynamo can be placed on either the light or the power busses, and has a circuit breaker, separate equalizer switch and an ammeter. Three volt meters on the four panels, connected up from multiple-point switches are supplied. Across the tops of the three feeder panels are two recording voltmeters and six ammeters, one ammeter each for the North Building, the North West Building, the West Building, the Main Building, the Main Building Addition and one unassigned or blank. The amount of current supplied to each building is thus separately indicated. Each of the feeders has a circuit breaker, these arranged along the bottom of the board, except that for the North Building, that in which the switchboard is located, in which case the various smaller circuits are arranged on the switchboard with individual circuit breakers instead of one main one. The North West Building houses an elaborate printing establishment which the company has furnished to do all its printing, and in this case, a power feeder is provided separate from the light, with circuit breakers in each case. Below the recording voltmeters, which are on the center of the three feeder panels, are two large wattmeters, one for recording the total energy supplied through the light busses and the other for all the energy supplied for power. The accompanying photograph shows the switchboard before the indicating instruments were in place.



Cross-Section of Main Pipe Tunnel.

The architect for the buildings is Mr. George B. Post, of New York, and all engineering work in connection with them was done under the supervision of Mr. Amory Coffin, his engineer. The power and heating piping and the ventilating apparatus was installed by Messrs. Baker, Smith & Company, of New York, and the electric work, for which Messrs. Pattison Brothers were retained as consulting engineers, was done by Messrs. Hatzel & Buehler, of New York. The switchboard was constructed by the General Incandescent Arc Light Company. The elevators were installed by the Otis Elevator Company, for which Messrs. W. T. Hiscox & Company, of New York, were sub-contractors. The coal and ash handling apparatus was designed by Mr. T. Amory Coffin, of New York. Mr. Tysilio Thomas is superintendent of the building and Mr. J. P. Russell, operating engineer.

The New Power House of the Twin City Rapid Transit Company of Minneapolis will be a 255x154-foot building 87 feet high, with two 16-foot Custodis stacks 235 feet high. There will be twenty-four 550-horse-power Babcock & Wilcox boilers equipped with Jones underfeed stokers and Mead coal and ash conveyors. Five 5,000-horse-power Allis vertical cross-compound engines direct-connected to 3,500-kilowatt General Electric generators will be installed to furnish current at 13,200 volts. Blake vertical marine condensers, Dean feed pumps and Stilwell-Bierce & Smith-Vaile heaters will be used.

Proposals for Building Jetties and dredging channels at Galveston, Tex., are invited by the U. S. Engineer Office, as advertised in The Engineering Record. The total estimated cost of the work is about $2,000,000. The approximate quantities for the jetties are 172,000 tons large stone blocks for covering riprap, 31,500 tons large riprap, 38,000 tons small riprap, and 80,000 linear feet of logs in cribs and spurs. The channels will require the dredging of about 12,850,000 cubic yards of material, as estimated by the engineers. Inquiries for specifications and further information should be addressed to C. S. Riche, Captain of Engineers, at Galveston.

Report of the Chairman of the Committee on Sewerage and Sanitation.

Presented to the American Society of Municipal Improvements by Prof. A. Prescott Folwell.

Municipal Sanitation.—The present chairman of this Committee, in looking over the "Proceedings" of the Society, was impressed by the fact that while many papers have been presented in the past nine years on sewerage, relatively little attention has been paid to sanitation; to be definite 21 papers have been devoted to sewerage and but 5 to any other subject which might be classified under sanitation, aside from those upon water-supply, garbage and refuse disposal, and parks, which subjects are covered by other Committees. The papers presented by the Committee this year include none on any branch of sanitation other than sewerage, and it therefore seems proper that it should make some report upon the many neglected but important subjects included under this general title. And it seems to the writer that the greatest service which he can render within the limits of a brief report is to call attention to the importance in municipal improvement of certan sanitary problems other than those included under the heads of sewerage, water supply, garbage disposal and parks.

It is one of the advantages of this Society that its members occupy various legislative and executive positions, and consequently each subject is, or is supposed to be, discussed from all, or many, points of view. A very large percentage of the papers, however, are presented by civil engineers, and this must result, it seems to me, in the loss of the benefit due to diverse view-points, and this especially to the engineers themselves. It seems probable that the reason the neglected branches of sanitation to which I wish to call attention are neglected is that they require but slight services from the engineer. This predominance of engineers among the list of authors of papers is not, I feel sure, because they have more of interest to present to the Society, nor because they are a leisure class, and I have prepared this paper in hope that it may suggest to some of the non-engineering members that they can give the Society instructive information on these subjects. I speak from a selfish point of view, hoping as a result of these remarks to ultimately receive much more information than I give. I propose therefore to name some of the directions in which sanitation can effect municipal improvement, and discuss each in the most general way only.

A list of such would include the collection of vital statistics; abatement and prevention of nuisances, including smoke, noise, odors, hideous and light obstructing street signs and buildings; the providing of public fountains, baths, latrines and convenience stations; food inspection; prevention and treatment of communicable diseases; hospitals; abattoirs; the disposal of the dead; as well as the drainage of wet lands, extermination of mosquitoes; consideration of effects of trenching and other earth excavation on the health of a community. Sanitation forms but a small part of the benefit afforded by many of these; but all of them, with many not mentioned, work in part to the sanitary betterment of cities.

Vital Statistics.—The collection of vital statistics is given more attention in Europe than in America, but our cities are moving rapidly into line. A brief consideration will show how important such statistics are. All practical or applied sciences are based upon the results of observations, and these sciences can not be more accurate than the data upon which they are based. Moreover, a general law dealing with complex natural phenomena can ordinarily be learned approximately only, and the more the number and the greater the range of such phenomena which are compared for this purpose the greater the probability of accuracy in the statement of the law. Our efforts to improve the sanitary conditions of the cities must be guided by our understanding of the laws of health and of life as affected by external conditions, and our success can not be expected to be greater than the accuracy of such understanding. This understanding of the law, in other words our knowledge of sanitary science, is derived wholly from observation, and its application along any line will generally be successful in proportion to the number, range and accuracy of observations made along the same line; not directly proportional to the number it is true, but proportional to some root of the number. As an illustration: it has been claimed that wood-block pavements are unhealthful, because of their supposed tendency to absorb water; but sufficient data relative to the health conditions of various communities which are and which are not provided with wood-block pavements and have otherwise similar conditions affecting their health, have not been collected, and this question can not be satisfactorily settled. Again, data recently collected seem to demonstrate that malaria can be prevented by suppressing breeding places for mosquitoes, and a way seems to be opened to prevent the spread of this disease.

Most of our large cities require every physician, midwife, undertaker, and clergyman to make returns to some public officer of all births, deaths, and marriages at which they have served; and also that physicians report immediately all cases of communicable diseases. In many cases fear of isolation or of quarantine prevents the reports of sickness. (Rochester reports for 1901 31 deaths from typhoid and only 102 cases or a fatality of 30 per cent., while the average for the past five years is 25 per cent. The average percentage of deaths from typhoid in other cities seldom exceeds 12 per cent., and the general average is 10 per cent. Rochester physicians therefore seem to be peculiarly unskilful in treating this disease, or delinquent in reporting cases). Now it is the sanitarian's part to prevent rather than cure diseases; consequently the record of cases of sickness are more important to him than those of deaths, but are often incomplete for contagious diseases and altogether lacking for all others. Would it not furnish very important data to the sanitarian if every case of sickness were reported to him? A copy of the city map constructed for each disease, in which each case was indicated by a dot, would undoubtedly be of great assistance in detecting local causes.

Much as the present system at the best lacks of satisfying the sanitarian, it is still of great value to him, and it is to be hoped that cities which are not now requiring and publishing the returns of vital statistics will be brought to see the advisability of doing so, and that the scope of the records be enlarged along the lines indicated. The necessity for this is illustrated by the statement in the Report of the Wisconsin State Board of Health for 1900 "that practically our vital statistics, so far as they are made to the different registers of deeds of the different counties, are absolutely useless"; also in Massachusetts, which is distinguished for its advanced standing in sanitary matters, 1 town of more than 5,000 population, 14 of between 1,000 and 5,000, and 66 of less than 1,000 population failed to report any vital statistics in 1900.

Abatement and Prevention of Nuisances.—City life is an artificial life, and natural processes can not be relied upon in urban surroundings to maintain unassisted sanitary conditions, it being more difficult there for nature to restore a disturbed equilibrium. Moreover, the denser the population the more intense becomes the mutual reactions of human deeds and misdeeds. It is, therefore, necessary for the citizens, individually and through their government, not only to assist nature to restore a normal condition of elements—air, water and earth—but to prevent the pollution of these which cause unsanitary conditions; and also to protect each citizen from the effects of the creation by his neighbor of such conditions. Most of these conditions are included under the general head of nuisances; although many of the nuisances so classified by law are offensive to the senses rather than dangerous to health, and so are outside the scope of this report. Unsanitary conditions are created by the smoke nuisance, by the odors from some chimneys, by exposed excrement, by flooded urban land, by anything which totally excludes direct sunlight from a dwelling, and by nerve-racking noises. Cities should encourage each other to suppress these nuisances by reporting successful methods and by rivaling each other in faithfulness in applying them. The smoke-nuisance seems to be especially troublesome; while the public needs awakening to the importance of sunlight as a health-preserver, and of the effect of jarring noises in producing nervous disorders and through the nerves aggravating many others.

The extreme eastern cities have been practically free from any smoke problem until within the last few months, but the scarcity of hard coal has led to the use of soft wherever possible, with the resulting dense smoke, and it is possible that some difficulty may be experienced in compelling urban coal consumers to return to anthracite when it becomes available; so that the nuisance may become more widespread than ever before, and methods of combatting it of more general interest. The more common method first tried by most cities is that of placing an ordinance upon the books—and it has been proven as commonly inefficient. Probably the greatest success has attended moral suasion combined with eternal vigilance, moderation, and common sense. To apply these some practical method must be known which can be urged as an alternative to the objectionable methods complained against. It will not be enough to say, "you must not make so much smoke," but an answer must be ready for the retort, "are we then to shut down the factory?" The argument frequently advanced that the escape of carbon in black smoke causes a financial loss which it will pay to prevent can not be proved, it is thought, since such matter amounts to but a small percentage of the coal consumed (15 pounds of soot per ton of coal in the blackest smoke, or about 0.7 per cent.), and its value is not often equal to the cost of smoke consumers. It does not necessarily follow, however, that methods cannot be adopted by large plants which, while greatly decreasing the amount of smoke, will cause an economy of maintenance. The more complete burning of gases, and the more uniform and higher heat resulting from continuous stoking by mechanical stokers and from better oxidation by mechanical draught, larger grates, and other similar devices, are well worth while from the owner's view point. In this as in other reforms the public must be educated to expect better results, and then the owners must be made to feel the popular displeasure by detecting and publishing the names of offenders. This method, rather than spasmodic prosecution, has proved most successful. And the public sentiment must not be taken for granted; where, as was the case in at least one city, a pride is taken in the smoky atmosphere as indicating manufacturing activity and prosperity, anti-smoke legislation can have no effect.

One of the evils of a smoky atmosphere is the excluding of sunlight. Another cause of darkness, dampness and dirt is the height of modern buildings. In hundreds of buildings in many of our large cities are office rooms, sales rooms, sleeping rooms, which have never received one ray of direct sunlight. Darkness, dampness and dirt are the ideal conditions for the preservation and dissemination of many if not all species of disease germs. Sunshine is the most effective universal germicide known. Not only germ diseases, but afflictions of the eyes and nerves with probably many others, can be traced to such conditions as their cause. The rule which has been adopted in London, is that no building shall be so high as to rise above a line drawn at an angle of 45 degrees with the horizontal from the base of any building opposite either its front or rear; and I believe that the violation of this rule must in the near future cause weak eyes, pale cheeks, consumption and generally lowered vitality in large numbers of the clerks and business men of our largest cities.

Food Inspection.—Another class of preventative action is that of food inspection. Many cities and most states have on their books laws against food adulteration, the enforcement of which is in the hands of special agents. Few of the adulterations used are injurious to anything but the pocketbooks of healthy adults; but infants and invalids may receive great harm from so-called embalming or preservative substances. In the neighborhood of my own home the state inspector has found half of the milk dealers selling milk adulterated with formalin, borax and similar preservatives. Diluted milk may also be injurious, to infants especially, by depriving them of the full amount of nourishment required. Food inspectors are employed by all of the cities having more than 250,000 population, by all but 5 of the 23 having between 100,000 and 250,000 population; by 29 of the 40 having between 50,000 and 100,000 population; and by 36 of the 57 having between 30,000 and 50,000 population. There seems to be no relation between the numbers of inspectors employed and the population; Rochester employs twice as many as Newark, for instance, although having but two-thirds of the population; and New Orleans has three times as many as Philadelphia, whose population is more than four times as great.

The prevention of the spread of communicable diseases is in the power, and is consequently the duty of the city. Aside from the protection of the milk and water supply, this is best effected by quarantining and by isolation hospitals; by the use of disinfecting apparatus; and by compelling a proper care and disposal of the bodies.

Disposal of the Dead.—The disposal of the dead, by cremation or by burial, and the location of burial grounds are important subjects. The burial of New York's dead requires annually about 50 acres, or a square mile every 12 years. In view of this the question of cremation may well be considered by large cities where the cemeteries must ordinarily be situated several miles from the centers of population. There are certainly arguments in favor of substituting the crematory for the "potters field." There were 26 crematories in operation in the United States in 1901 and the number is slowly increasing; 13,281 bodies were cremated in this country in the last quarter of the nineteenth century. Even now, however, not more than one-fifth of one per cent. of the dead are cremated in the United States. Data concerning the cost of cremating and of burying the pauper dead in large cities would be of interest. Assuming the necessity of the cemetery, its location as affecting sanitary conditions and its treatment as a breathing spot or a place for a quiet outing are worthy of more consideration than is generally given them.

Abattoirs and Markets.—The providing of public abattoirs and markets and the proper regulation of them will go far towards insuring the people against decayed or stale vegetables and meat, "bob" veal, and other unhealthful kinds and conditions of food. More than 100 cities of the United States own their markets, and more than 50 of these have a population of less than 50,000; the South showing more in proportion to the total number of cities than any other part of the country. While the smaller cities may not be able to afford the public buildings, neither can they afford to do without careful and frequent inspection of all private slaughter houses and markets. A health officer, generally under the direction of the local board of health, is in most cases the agent for such inspection.

Public Fountains, Baths and Convenience Stations.—Public fountains and drinking places, the latter especially, are now considered a necessity in all large cities, and many small ones find them worth while. The cooling effect of a fountain in a small city park located in a congested district may mean increased health and even life to many a child and invalid, and render existence more tolerable to many a healthy adult; while the restful effect of splashing water is particularly soothing to nerves wearied of a city's jarring noises. In cities and towns of all sizes drinking fountains for horses, cattle and dogs are even more necessary than for men. Information concerning the amount of water required to maintain these and possible methods of preventing waste; the best locations for them and the number required; the supplying of both ordinary and iced water to human beings, and the automatic cleaning of the cups used; these and other points will reward investigation.

Public baths are of late becoming a more common municipal institution. To mention a few examples only, Boston, Mass.; Yonkers, Fonda, and New York, in New York; Newark, N. J.; Pittsburg, Pa., Chicago, Ill., and San Francisco, Cal., have public baths. In Boston's public schools baths are provided and are compulsory where the necessity for them is evident. In 1900 36 cities of the United States had either all the year or summer public baths. In these 36 cities are included all three of those having more than 1,000,000 population; 2 of the 3 cities having between 500,000 and 1,000,000; 3 cities having between 250,000 and 500,000 population, or $33^1/_3$ per cent.; 6 cities having between 30,000 and 50,000, or 10½ per cent.; 6 having between 10,000 and 30,000, or 2 per cent.; and 5 places having less than 10,000 and more than 3,000, or 0.5 per cent. In New York State, by an act of 1895, all cities of 50,000 inhabitants or over must provide public baths.

In Buffalo, Rochester, and Philadelphia—probably in other cities also—are public wash-houses for the convenience of the poor whose contracted living quarters do not admit of washing in their so-called homes. Both of these institutions encourage and assist in cultivating that personal cleanliness which must go hand in hand with perfect municipal cleanliness. A collection of information concerning the location, structural and mechanical details and administration and popularity of these would be helpful to many cities which are contemplating the introduction or extension of these efficient aids to sanitation.

In our larger cities latrines or convenience stations are a necessity which is but poorly met. Most large parks contain such stations; but in the business districts where thousands congregate daily the saloon or hotel for men and the larger dry-goods stores for women are looked to to furnish as a convenience (which the sensitive person feels should be paid for by a perhaps unwished for beer, cigar or ribbon) what the city should provide for all as their right. European cities are far ahead of us in this respect, although we would not be satisfied with the regard paid by them to more or less conventional modesty. New York has made a beginning of supplying such stations underground in the business district. The home water closet in the cellar, basement, or under the back stairs has been pretty well abolished; and while an underground municipal closet is better than none, it would seem that the same arguments which were advanced against the private dark-closet would hold against the public one.

Drainage.—There are two classes of wet lands often found in and near cities, and these should be drained—natural swamps, and lands flooded by street grading which are too low for a natural surface outlet. The latter are objectionable because making the ground in their vicinity moist for a large part of the time and thus causing damp cellars and unhealthful ground air; because they are used as convenient points for drowning cats and dogs and for the secret and convenient disposal of garbage and other refuse; and because they form breeding places for mosquitoes, which are both unpleasant and, it is believed, dangerous as carriers of malaria. Natural swamps are objectionable for the latter reason, as well as because they might if drained be utilized to some profit.

Earth Excavations.—The danger of sickness resulting from trenching or other excavation in the north is not so great as in the south; and yet epidemics of what is generally called malaria have undoubtedly accompanied many cases of wholesale excavation for sewerage or water works systems even at this latitude; while in the south yellow and other fevers are thought to result from excavations in hot weather. That such results can be avoided was apparently demonstrated in Havana, during the United States occupancy, when a large percentage of the streets was dug up for sewers and pavements during all seasons, while the sickness in the city meantime was but a small fraction of that which had always existed previously; the treatment of all fresh earth with chlorine obtained by the Woolf process being credited with the innocuousness of the excavations. Data going to prove or disprove the popular impression that excavations cause sickness, or to demonstrate under what conditions of temperature, soil or air this is true, would be of value.

Oiling Roads has been investigated by City Engineer E. W. Chase, of Colorado Springs, who reported that the best work he saw was in Chino, Cal., where the methods explained in The Engineering Record of March 30, 1901, are followed. He says that the people along the roads which have been oiled were opposed to the work, but after the oil was applied they discovered that it was not so bad as had been reported; and along roads and streets where the oil has been properly applied, or applied with an indifferent degree of propriety, the people are more than satisfied. Teamsters are especially enthused over the oil paved road, as it does away with the dust and mud. The road is somewhat heavier than when paved with other material, but is lighter than the natural soil or even the graveled road. The color of the road is a dark brown, pleasant to the eye, and quite in contrast to the glare of our own streets. For a short time after the road has been prepared with oil, there is quite a heavy odor, but Mr. Chase did not find it more unpleasant than that of an asphalt-paved street.

The Scope and Purpose of the Irrigation Investigations of the Office of Experiment Stations.

By Elwood Mead, Irrigation Expert in Charge. From the Report of the Office of Experiment Stations.

With relation to rainfall the territory of the United States is divided into three parts—the humid, the subhumid, and the arid. In the humid region the rainfall is ordinarily abundant, but there are occasional seasons when it is insufficient for the raising of crops, and in most seasons there are times when crops are checked in their growth by periods of drought lasting from a few days to a few weeks. The subhumid region includes the territory where dry periods in summer are the rule. The injury to crops in subhumid regions is due to two causes—insufficient moisture and great irregularity in its distribution. The arid region includes the areas where cultivated crops can not be grown by the aid of rainfall alone.

Geographically, these regions are arranged from east to west, although no exact line can be drawn separating them. The humid region, as generally described, includes all of the United States westward to a line which would cross Nebraska and Kansas about half way between their eastern and western borders. The subhumid region lies between the humid and arid regions, extending from the Gulf of Mexico to Canada and including irregular areas in the different Pacific coast States; while the arid region includes all the territory lying west of the eastern subhumid belt with a considerable exception along the Pacific coast, and with smaller local areas in each of the arid States.

Irrigation is employed as an aid to agriculture in all of these regions. It is a necessity in the arid region, of great value in the subhumid district, and is proving highly profitable in the growing of certain crops in the humid region. There are also large areas in the recently acquired insular possessions of the United States where irrigation is required, and where the value of the products permits of a large outlay to provide for its use. The work of the irrigation investigation of the Office of Experiment Stations covers therefore the whole of the United States.

Investigations in the Arid Region.—The greater part of the irrigation work of this Office has been carried on in the region where farming is impossible without the artificial application of water to crops. This includes all of the Territories of Arizona and New Mexico, the States of Colorado, Utah, Nevada, Montana, and Wyoming, and large parts of California, Oregon, Washington, Idaho, North Dakota, South Dakota, Nebraska, Kansas, and Texas. The greater attention paid to the problems of this section of the country is justified by the fact that here irrigation is a necessity rather than a valuable adjunct to agriculture. It measures agricultural settlement and very largely controls the development of other industries, because both the cost and comfort of living are very largely determined by the production of a home food supply. In the regions farther east, the adoption of irrigation is determined by whether or not it will improve conditions already favorable, but in the arid region it is the choice between civilization and desert condition.

The work in this region has followed two general lines—agricultural and engineering, legal and social. Of these, the legal and social problems present the greatest difficulties and stand most in need of an early solution. The success of irrigated agriculture in this region requires first of all the creation of institutions which shall offer a just and adequate foundation for future development. Such a foundation requires that the users' rights to streams must be clearly defined in order that those who now use streams and those who expect to use them may understand how much of the water supply is appropriated and how much remains open to appropriation. The litigation and controversy which now menace communities and which are a constant source of anxiety and loss to irrigators should be brought to an end. In order to effect these desirable reforms, a knowledge of certain essential facts is required. Among these are the quantity of water required to grow crops, the losses from seepage and evaporation in distribution, the character of the control over streams already vested, and the kind of administrative measures needed to insure effective division of streams among the multitude of users who depend thereon. Specific information along these lines is indispensable to wise and effective action in the future either by the Government or by individuals. It is the information which should have been gathered at the very outset of this development, but the long delay in its collection renders it all the more urgent that it be carried on now to an early and effective completion.

The work along agricultural and engineering lines has been largely carried out in cooperation with the agricultural experiment stations of the different States, and with the State engineers in States having such officials. By undertaking systematic work on some of the general problems of irrigation, this Office has been able to supplement and extend the work of the experiment stations, and at the same time has aided them to take hold of other studies, such as problems relating to the economical use of water on different crops. It makes possible the bringing together of observations from the whole country. It promotes uniformity of methods in these investigations and thus gives to the results a wider value than is possible with each station working independently and alone. It brings together the experience of the whole irrigated West for the use of each locality, and shows the farmers of one section where their practices can be improved by adopting those of other and oftentimes far distant sections.

Agricultural and Engineering Problems.—The studies of the practical questions involved in diverting water from streams, transporting it through canals and ditches, distributing it over the land, and determining the requirements of different crops have been carried on in all of the arid and semiarid States with one exception. In general, the results of this work show that the losses in distribution are much greater than has usually been supposed, and that the quantity of water required, where these losses are included, is somewhat greater than has been estimated by many writers on the subject or stipulated in many water-right contracts. The stations for the measurement of the duty of water are scattered over nearly one-third of the United States. The averages of the different measurements for the past two years show a surprisingly close agreement when this wide range of conditions is considered, as appears from the following summary:

	Feet.
The average depth of water applied to crops in 1899 was	4.35
The average depth of water applied to crops in 1900 was	4.13

One of the results of this work has been to show the importance of keeping canals in good condition, and to emphasize the benefits resulting from diminishing as far as possible the losses by percolation. Measurements show that the loss from seepage and evaporation in ditches and canals varies from 15 to 70 per cent. of all the water taken in at their heads, and that by far the greater part of this loss is due to seepage. Formerly many believed that most of the loss was due to evaporation, and was therefore beyond the power of man to remedy. Now that it has been demonstrated that the water disappears through the sides and bottoms of ditches and canals, steps can be taken to improve these channels and the loss stopped to a great extent. Improvements of this character will increase the area which can be irrigated, and save much land for productive agriculture which would otherwise become swamps and marshes.

The difference between the high and low duties obtained under practically the same conditions shows that where water can be had in abundance the natural tendency is to use too much, resulting in a reduction in the yield of crops, a temporary injury to the land, and a limitation of the area which can be irrigated with the available water supply.

In many localities a lavish use of water has converted areas once arid into alkali marshes, of which the only product is cat-tail flags, and made drainage necessary at a cost fully as great as was required to provide the water supply in the first instance. The need of this drainage might have been avoided in many cases had canals been constructed with more care and the evil results of overirrigation appreciated at the outset.

The soils of the arid region are rich in mineral ingredients. This is due in part to their origin and in part to the scanty rainfall, which has not been sufficient to wash out the soluble elements, as has been the case in humid regions. Because of this there are large areas which are highly charged with alkali. The tendency of irrigation is to leach these salts out of the higher grounds and concentrate them in the lower lands. Evaporation tends to bring them to the surface, where they accumulate in such quantities as to kill vegetation. The remedy is to be found in drainage, and this investigation has been called upon to assist in solving the larger engineering and legal problems connected with the formation of drainage plans. As some of these districts embrace in the aggregate many thousands of acres, in which not only the alkali but the water plane has risen until it has reached the surface, it is necessary that the plans should be comprehensive, and must include provision for removing the surplus water as well as the salts which are to pass with it. Drainage studies must include the causes of their being flooded and a determination of the source and volume of the water to be removed. Drainage and irrigation are a part of one whole, and their investigation should be carried on together. The office is now engaged in this work in Colorado and California.

The publication and circulation of the facts being gathered regarding the injuries resulting from excessive losses in distribution or wasteful use will go far to prevent a recurrence of such injuries in other localities where irrigation is yet in its infancy. Another result will be the reclamation of more land than would otherwise be possible.

Instruments for Measuring Water.—In carrying on the measurements of water it was found that the instruments used were in many cases not suited to the work required of them, and were so expensive as to limit their use generally to Government and State work. With the progress of the work of the investigation there has been a growing demand for instruments which will do accurate work and at the same time be within the reach of canal companies and individual irrigators. The instruments most used are the current meter and the register for keeping a continuous record of depth of water at any point. Efforts have been made to cheapen these instruments and at the same time increase their efficiency. Little has been accomplished with the current meter, but the water register has been so simplified as to reduce its cost by more than half without any sacrifice in accuracy.

Legal and Social Problems.—The measurements made to determine the quantities of water used and the losses from canals has another object besides the improvement of agricultural practices. It is a principle of irrigation law, in theory at least, that rights to water are based on beneficial use; that is, a person or company can maintain a right to only so much water as he or it can put to a beneficial use in irrigation. It is of first importance, therefore, to know how much water is needed to grow crops on a given area, in order that courts and boards of control may intelligently determine the amount of rights to water, and officers charged with this duty be able to prevent wasteful use by those who have early rights or a desire to monopolize the supply. Because of the lack of this information, rights to water have too often been established without any regard to the volume of the stream, the capacity of canals, or the needs of the land to be irrigated. The attempt to utilize such excess rights can lead to nothing else than continued litigation and trouble. The facts gathered in these investigations are already being eagerly sought as a guide in the establishment of water titles, and they are certain to prove one of the most effective agencies in preventing erroneous or excess decrees in the future.

A knowledge of the extent of the losses from canals is also necessary to the proper distribution of the supply. Appropriations usually contemplate the measurement of the volume allowed at the head of the canal, hence the amount granted should be great enough to meet all the necessities of crops and also to allow for losses in transit. If this estimated loss is too large the volume taken in at the head gate will be greater than the needs of the land irrigated, but if too small irrigators will suffer. Excessive allowance for these losses puts a premium on poor construction, hence data is needed to show what are reasonable losses and to prevent anything above this. Where losses can be stopped appropriations should be cut down in order to compel ditch owners to make them economical water carriers. Losses which can not be stopped should be provided for.

Along with the observations and experiments in the use of water has gone a study of the laws and customs which control its distribution. This study reveals the fact that the development of irrigation law has not kept pace with irrigation engineering or agricultural practices. As the need and value of water has increased, engineers and farmers have found ways to conserve the supply and economize in its use. But it is too often the case that this increase in value has only added to the uncertainty as to titles, since it presents greater inducements or temptations to those holding inferior rights to try to secure a larger share of the supply. The absence of tribunals for the final establishment of water titles, and the lack of public control over the division of streams, puts upon the holders of the older and better rights the burden of protecting their interests either by force or in the courts. The greatest need of irrigation is legislation which will end this uncertainty and controversy, but from the nature of things such legislation is hard to secure. Conservative legislative bodies are slow to act, and they often have not the information on which to base intelligent action, even if they have the desire to do all that should be done. The conflicting views of appropriators of water make it impossible to enact any effective law which will not be strongly opposed, or which will not work hardship to some individual. The work of this Office is limited to collecting and publishing information, with discussions by experts whose broad views enable them to better interpret the facts than is possible where details and local interests obscure the general policies which should prevail.

Studies of irrigation laws and customs have been made in connection with the measurements of water in all the arid States and Territories. Comprehensive studies of irrigation laws and customs have been made in California and Utah. A report dealing with the agricultural situation in California has just been published. This study was undertaken in response to a petition from the citizens of that State in the hope that a clear statement of existing conditions would help toward the enactment of a comprehensive code of irrigation laws.

A similar study has been made in Utah, and the reports of the different observers are about ready for publication. These reports will show that titles to water in that State are far from being stable or secure, and that there is urgent need of a cheaper and simpler method by which they can be permanently settled.

The conditions found in California and Utah are not peculiar to those States. They are common to nearly all the arid States. Their betterment is the first step in the successful or the complete use of Western water supplies. As has been said, the work of this Office can not extend to the enactment of laws. It must stop with showing existing conditions and pointing out remedies for the evils found. With this end in view the laws of not only our own States, but of Canada, Australia, Europe and Egypt, are being studied in order that the best lessons from the experience of all the world may be within the reach of those who must enact the laws which will protect and encourage investment in irrigation enterprises.

Not less important than the system of irrigation laws is the character of the organizations which control the water supply under these laws. Irrigation is essentially a cooperative industry. In its beginning small ditches were sometimes constructed by individual farmers, but opportunities for such construction are practically all utilized. The large canal covering the lands of many farmers is in most remaining cases the only possible one; hence the existence of the industry calls for organization and cooperation, and in most cases not only cooperation of farmers but of capitalists as well. The problem to be solved here is how to secure returns upon the capital invested and at the same time keep the land and water within the reach of the poor man, the only man who is seeking for a new home. This problem has not been solved in this country. It is one which must be solved before irrigation can go much further.

Under the laws of many States water rights are granted to the canal companies. In those States the rights of the farmers depend on the form of the organization of these companies rather than on the laws. The reports of this Office show that the peace and prosperity of many communities, as well as the economy with which water is used, depend almost wholly on the rights of the individuals under the companies. This study of organization and its effect on development is being carried on wherever the measurements of water have been made.

In this connection it seems proper to reiterate the views expressed in a former report on the subject of water rights. The first step in future development should be to reach an enlightened agreement regarding the true character of these rights. The idea of private ownership in water apart from land can not prevail without creating institutions essentially feudal in character. To give to companies or individuals the control of streams, and make the farmers who use those streams dependent for their rights on the conditions which these companies impose in private contracts, is to make the water company the practical owner of the land it serves and the irrigator and farmer a tenant. A proposition which would contemplate turning over all the land of the West to private monopolies and making those who have homes upon it dependent upon these monopolies would not command popular support, but the idea of private ownership in water, amounting to a virtual monopoly of this vital element, has been permitted to grow up in some sections of the West. To a certain extent it has obtained recognition in legislation and protection in judicial decrees and decisions. Such a doctrine meets with no favor in other irrigated lands, and should in this country give place to the more just conception that rights to water should be restricted to the right of use, and that ownership should not be vested in either companies or individuals, but in the land itself. When this principle is adopted the control of water is divided like the control of land among a multitude of proprietors; water monopoly is impossible, and no other abuse or injustice is encouraged. Years of experience in other lands and the limited experience of this country have abundantly proven that peaceful and orderly development can not be realized except as water and land are united in one ownership, and canals treated as public or semipublic utilities rather than as a means of fastening a vicious monopoly upon communities.

Irrigation in the Subhumid Portions of the United States.—The subhumid portions of the United States possess certain advantages in the employment of irrigation which must in time greatly extend its application in this section of the country. There is a greater rainfall and a more humid atmosphere than in the arid region, so that a given water supply and a canal of given dimensions will irrigate more acres than in the region wholly arid. Much of the subhumid district east of the Rocky Mountains is remarkably well suited to the distribution of water in irrigation. The slope of the country away from the mountains is about what is needed for the construction of canals and the distribution of water over the ground. The practical obstacles to be encountered, either of an engineering or agricultural character, are less, as a rule, than in either the arid or humid sections, and the cost of supplying water is proportionately reduced. Important studies have been made during the past year in this region by Prof. O. V. P. Stout, of the Agricultural Experiment Station of the University of Nebraska, acting under the direction of this Office. This station is in a section where lands have been cultivated for many years, and where agriculture is a demonstrated success without the aid of irrigation. The question to be settled is whether the use of water on general farm crops will give sufficiently increased yields to repay with a profit the cost of providing the water supply and distributing it over the land. Results thus far secured show that it will. The maximum yield of corn in this locality without irrigation is about 40 bushels per acre, while the lands irrigated during the past year yielded from 40 to 60 bushels per acre, with a maximum yield in rare instances of 90 bushels per acre. Two adjacent fields, one irrigated and one depending on rainfall alone, yielded 66 bushels and 20 bushels per acre, respectively.

The methods of diverting and applying water were those of the ordinary irrigator; the soil and climate were typical of the territory which extends westward from the Missouri River for

250 miles, and the results can fairly be taken as representing what may be expected in seasons of scanty rainfall throughout the greater part of the subhumid district.

Irrigation in the Humid Portions of the United States.—The experience thus far gained makes it certain that irrigation is destined to be an important means of improving the already prosperous conditions of agriculture in humid and subhumid portions of the United States. The possibilities along this line have not yet been fully established, but the lessons thus far learned seem to be that it has a wide field of usefulness wherever intensive agriculture is practiced or where insurance from drought is important. The irrigation investigations of this Office now include a study of the problems of irrigation in this region—in Wisconsin and Missouri, to determine what can be done in the States of the Middle West; in New Jersey, to ascertain its field of usefulness in the North Atlantic States; in the Carolinas and Georgia, to determine its possibilities in the South Atlantic region; and in Louisiana and Texas, in connection with the increasing use of irrigation in the production of rice.

During the past season studies of the benefits of irrigation in Wisconsin have been carried on under the immediate direction of Prof. F. H. King, of the College of Agriculture of the University of Wisconsin, at the station farm at Madison and at Stevens Point. In both cases the water supply had to be provided by pumping, and records have been kept to show the amount of water used, the time of its application, the cost of pumping, and the increase in yield of the various crops to which it was applied. Owing to the exceptional drought which prevailed, the results were highly favorable to irrigation. If the results of one season's trial would justify drawing definite conclusions, it would be that irrigation in Wisconsin is a marked success; but that is not the case, and it is the intention to continue these studies for a number of years, the work being broadened so as to include all the crops which promise beneficial results.

A cooperative investigation in irrigation is also being carried on between the Missouri Experiment Station and this Office at Columbia, Mo., under the direction of Prof. H. J. Waters. Apples, strawberries, and nursery stock were the crops receiving the most attention, arrangements for the water supply not having been completed in time to prepare for its application to other staple farm crops. Careful records were kept of the quantity of water used, the cost of furnishing it, and the time of its application. The report of Professor Waters states that "the season was very disastrous to strawberry plants, many of the old plants dying, and practically no runners being formed under ordinary treatment. The irrigated plants developed strong crowns, and undoubtedly stored an abundant supply of food for next year's crop. The strawberry nurseryman, the man whose business it is to supply plants for the commercial strawberry grower, will find in irrigation absolute protection against failure." It will require next year's record of the yield to determine the full measure of the benefits of this year's irrigation. Referring to the result of this year's watering of nursery stock, Professor Waters believes that nurserymen will find irrigation exceedingly profitable, that it will result in securing larger growth in young trees, trees with better formed heads, and possibly a saving of one year in the time when nursery stock can be placed on the market. He also believes that the protection of bearing trees from injury by drought is a matter of very great importance, because this injury often extends beyond the season when the scarcity of water begins.

In the North Atlantic States the large area devoted to market gardens makes security against drought a matter of much importance. Throughout this region the average rainfall provides sufficient moisture if properly distributed, but short droughts just at the time when the crops are maturing frequently cause heavy losses. In many years no such droughts occur, but they come often enough to make the growing of vegetables and small fruits uncertain. The problem to be solved is whether the saving of an occasional crop and the increased yield of many crops will repay with a profit the cost of providing a water supply. The study of these questions is being carried on by this Office in connection with the agricultural experiment station in New Jersey, Prof. E. B. Voorhees, director of this station, being in charge. His experiments, so far reported, have been limited to small fruits. They show that, in case of almost all varieties, the increase in the product of the irrigated tracts over the unirrigated ones was considerably more than enough to pay in a single season the entire cost of providing the water supply as well as the expense of applying it.

In addition to making experiments with small fruits, Professor Voorhees collected data from private parties in regard to the irrigation of various kinds of garden truck. In most cases the results were equal to those obtained in the experiments made under his personal direction, paying the entire cost of installing the pumping plants, with a profit, in a single season.

An analysis of the rainfall records at Philadelphia, covering a period of seventy years, shows that in considerably more than half the years there was a lack of rainfall in some one month of the growing season to seriously affect the yield of small fruits and garden vegetables, which constitute so large a part of the products of the Eastern farms. Taking Philadelphia records as typical of the eastern United States, and the results so far obtained in New Jersey as a basis for deduction, it will be seen that an irrigation plant would be a profitable investment for most of the farmers living where our large cities provide a ready market for small fruits and vegetables.

It is not likely that the water-right problems which are so large a factor in Western development will prove of equal importance in the East, owing to the larger flow of streams and the fact that the areas to be irrigated will always be restricted, but in many localities there are already indications that important legal problems will have to be solved before irrigation can safely assume the importance which its value will naturally give it. The work of this investigation along the legal and social lines can well be extended to this section. The experience of the West will in time come to be of value in solving the water problems of the East.

Among the important work which needs to be done in the East along agricultural and engineering lines is a study of the cost of installing and operating pumping plants for small areas. Something has already been done along this line and arrangements are being made to continue this more effectively in the future.

During the past season the problems of rice irrigation have received much attention from this Office. The investigations inaugurated have been principally along agricultural and engineering lines. In the Carolinas it has included a study of the methods of storing water to provide a supplemental water supply; the methods of diverting and distributing it over the fields and the problems connected with the regulation of tidal rivers so as to determine what may be done, either by the Government or by the concerted action of private individuals; and the construction and maintenance of levees for the protection of fields against floods or injury from breaks above or below.

Rice growing in the Carolinas and Georgia is not as important an industry as it was fifty years ago. In part, this decline is due to the cost of labor. The rice fields are located along the low alluvial bottom lands where the greater part of work must be done by hand. This leaves only a small margin of profit at present prices, and the danger of this being occasionally lost through breaks in levees or river floods has tended to retard a revival of what was once an important and valuable industry.

There seem to be two or three questions which this investigation can properly deal with. One is to what extent State or Government aid is required to assist in the regulation of streams, and to study the topography and watersheds of streams to ascertain what measures may be taken to furnish a supplemental water supply through storage.

The growing of rice on the uplands in Louisiana and Texas presents an entirely different condition of affairs. Here the industry has been from the first unusually successful, and it has increased until it has assumed a national importance, promising to make the United States an exporter instead of an importer of this staple product.

Aside from the agricultural questions peculiar to rice farming, the irrigation of these uplands presents new problems in canal construction and the lifting of water. In the arid region streams as a rule have a heavy fall, and it is therefore easy to get water onto the lands to be irrigated by gravity. In the rice districts the water supply is below the lands to be served, in streams which have hardly enough fall to produce a perceptible current, and the water must therefore be raised by pumps. Even with this expense, rice growing has proven remarkably profitable. The rice lands, which were formerly worth from $1 to $3 per acre, and used only for grazing, now sell for from $30 to $50 per acre, and yield an annual return equal to the value of the land. About 250,000 acres of these lands have already been devoted to rice culture, and much more is capable of the same use.

Along a few of the streams used more land has already been devoted to rice than the streams can properly water, and the question of protecting the early users against the demands of those coming later is pressing for settlement. Louisiana has no laws or customs affording this protection. The publications of this Office place at the command of the canal owners and lawmakers of that State the results of the experience of other States and countries, and will afford them the means of enacting a just and intelligent law governing water rights whenever such action becomes necessary.

A report will soon be published showing the methods used in irrigating rice and discussing the problems which have arisen in the rice districts. This investigation should be continued by the experts employed by this Office, whose familiarity with conditions elsewhere makes them especially fitted for the solution of the problems arising in this new field.

Irrigation in the Insular Possessions of the United States.—During the past summer officials of the Hawaiian Islands requested this Office to make such investigation of the irrigation problems of these islands as would furnish the facts needed in framing an effective code of irrigation laws. The need of such legislation is becoming urgent. Large investments in irrigation works to supply water for the growing of cane have made the subject of water ownership and control one of the most important internal questions of these islands. Proposals have been made by private parties to purchase from the government all of the water rights attached to public lands. Wise action on such proposals will be promoted by a thorough investigation of agricultural conditions and the prospective needs of irrigators. An agent is now engaged in collecting facts as to the use of water on these islands.

Large areas in Porto Rico to be productive require irrigation. Legislation will therefore be needed for the establishment of water titles and to protect the holders of these titles in times of scarcity. It is now admitted everywhere that if water laws and land laws had been framed and administered together in the settlement of the arid West many of the complications which now exist could have been averted. The opportunity is now open for inaugurating a comprehensive code of laws in Porto Rico which shall control development from the outset, and it is believed that an investigation to determine the facts on which such laws should be based should be inaugurated at once.

Interurban Road Improvements.

Extracts from a report to the American Society of Municipal Improvements, by Nelson P. Lewis, Chairman Committee on Street Paving.

Whenever suburban districts are added to our cities, there is immediately presented the problem not only of maintaining such improved streets or roads as the new territory may possess, but the extension of those improvements on a scale suitable to the needs and requirements of the community. The urban resident, too, is not content to be limited to the paved streets of his own town and to flounder in a sea of mud or be covered with dust whenever he attempts to leave them. He wants good roads leading out into the country on all sides, while those who supply his table with garden produce must have good roads on which to transport it. The prosperity of a city and the comfort of each citizen can be truly said to depend upon the character of the highways leading out of the city as well as upon that of the street upon which he lives or those which he traverses in his daily duties.

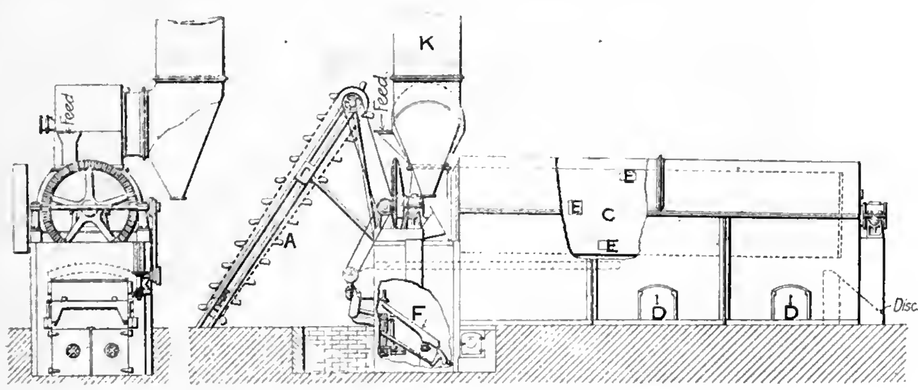
It is time, therefore, that the subject of roads, as distinguished from city streets, should receive the consideration which its growing importance merits. The building of a system of roads to connect different cities and towns, if left to the initiative of the towns themselves, would be almost impossible of consummation. The State alone is capable of planning and executing such an improvement. It is advisedly called "an improvement" for it should be complete in itself and result in unifying the Commonwealth as nothing else could do. The first State to take up this question on an extensive scale was New Jersey, which has now a splendid system of highways connecting nearly every city and village within its borders. Massachusetts has for some years been creating an excellent system of modern roads and in a manner characteristic of the old Bay State, her Highway Commissioners are doing their work with exceptional thoroughness, giving much attention to details of grade, alignment, drainage and the general appearance of the roadside. During the last few years New York has devoted much attention to the subject of roads and many miles of fine highway have been built and are under construction.

It will be seen that the propaganda which may fairly be said to have been started by the bicyclists a few years ago has been steadily gaining ground. The automobile is now an important ally of the good roads advocate, and the sane driver of the horseless vehicle who has some regard for the rights and safety of his fellows can add a great impetus to the movement, though at least one instance has come to the notice of your Committee where a proposition to bond a town for the purpose of building several modern highways was defeated by popular vote solely as a result of accidents caused by the outrageous disregard of the safety of the general public shown by the drivers of high speed automobiles. These high speed cranks are the worst enemy of the good roads cause.

But the building and maintenance of macadam roads is not only of interest to the small city and the good roads enthusiast. Many of our larger cities have miles of their streets so improved and they are, as a rule, grossly neglected, while such repairs as are made, are carried out in an unintelligent and extravagant manner. According to the bulletin issued by the United States Department of Labor in September, 1899, giving statistics of cities, 140 cities containing over 30,000 inhabitants have over 82,000,000 square yards of macadam, which is equivalent to more than 4,650 miles of roadway 30 feet in width. The proper building and intelligent care of such roads, therefore, cannot be a matter of indifference to our larger cities, but it is one of the most vital importance.

A Self-Contained Dryer.

The self-contained dryer shown in the accompanying illustration has been designed without any very heavy parts in order that it can be dismantled and moved to a new site without difficulty. It is enclosed in a steel casing, lined with firebrick on the sides, and the cover has a fire-proofing protection. The illustration shows the dryer fitted with the makers' type of mechanical stoker, but the furnace can be arranged with grates for burning any kind of fuel.



The Cummer Self-Contained Dryer.

The material to be dried is lifted by the elevator A into the feed hopper, discharging into the drying cylinder C, which is driven by the large pulley and gearing shown in the end elevation of the apparatus. The shaft of this pulley carries a cone pulley which drives the belt operating the stoker. The heated air from the furnace is drawn into the cylinder through the square openings E, and after passing over the material to be dried is forced up the stack K by a fan in the horizontal flue at its base. The holes E are protected by hoods which prevent the material from dropping out while permitting the free entrance of air. There are registers, D, in the sides of the casing, which are used for regulating the temperature of the air before it is admitted to the cylinder.

The dryer is made in several sizes by the E. D. Cummer & Sons Co., Cleveland, for use with coal, stone, marl, clay, slag, ores, concentrates and other materials.

Trade Publications.

The Massachusetts Fan Co., Waltham, Mass., has issued a special catalogue, No. 50, devoted to the Davidson propeller fan and its adaptation to heating, ventilation, drying and kindred uses. The fan is designed particularly for the movement of large quantities of air at comparatively low pressures and is constructed to operate at high speed, if necessary, being proportioned to withstand a rim speed of 10,000 feet per minute. The Company has also brought out two bulletins. No. 67 describes the Stirling disk fan and the Simplex ventilator fan, the former provided with 12 blades which overlap one another to prevent back lash and to effect a large air delivery against pressure. No. 68 illustrates the details of direct-connected motor-driven Davidson propeller fans.

"A Crocker-Wheeler Trolley Trip" is the title of an attractive booklet printed for distribution by the Crocker-Wheeler Co., Ampere, N. J. It describes a trip over the Flint Division of the Detroit United Railway from Detroit through the towns of Royal Oak, Rochester, Romeo, Oxford and Flint. At Rochester is the power house, which is equipped with Crocker-Wheeler electrical machinery.

The Chicago Pneumatic Tool Co., Fisher Building, Chicago, has issued a catalogue of air compressors which it builds in sizes ranging from a capacity of 95 cubic feet of free air per minute to 2,052 cubic feet and of the single, duplex and compound types. The book describes in considerable detail, by the aid of excellent halftone cuts, the various parts of the machines and gives some valuable information on the uses of compressed air and the effect of compounding, cooling, intercooling, aftercooling and reheating. A number of useful tables are also included.

The Fort Wayne Electric Works, Fort Wayne, Ind., has now ready for distribution three bulletins, an instruction book for the proper installation of Wood ammeters and voltmeters and a flyer devoted to the Wood Type A oil transformers. Bulletin No. 1028 describes in detail the Wood enclosed direct-current arc lamps for operation two in series on 200 to 250-volt circuits and five in series on 500 to 575-volt circuits and Bulletin No. 1029, enclosed direct-current arc lamps for 110-volt circuits. Bulletin No. 1034 covers standard small motor panels in sizes from 1/4 to 30 horse-power for 115, 230 and 500-volt circuits. These boards are equipped with automatic overload and underload release. Type A transformers, described in the flyer, have capacities of 0.6 to 50 kilowatts and primary voltages of 1,000 or 2,000 volts with secondary voltages of 50 or 100 and 100 or 200 volts.

A 77-page catalogue on "Electric Locomotives for Surface Haulage" has been published by the Baldwin Locomotive Works, Philadelphia, and the Westinghouse Electric & Manufacturing Co., Pittsburg. The standard types and classes are enumerated, and a general description of their construction, both the mechanical and electrical features, is given, together with tables of weights and characteristics of each class. Some 22 full-page reproductions from photographs serve to show their varied and widespread adaptation.

The Aceterator is an acetylene gas generator, adapted for out-door subsurface installation. It was developed to provide a generator that could be placed entirely outside the building and has allowed for the use of a large gas holder. A booklet describing it and the method of supplying illumination to a house may be obtained from Ralph B. Carter, sales agent, 26 Cortlandt St., New York.

The H. W. Johns-Manville Co., 100 William St., New York, has prepared for general distribution a booklet, Catalogue V, on Vulcabeston packing, which is composed of asbestos combined with vulcanizable gums to render the packing tough, pliable and yielding. It is furnished in sheets and rolls, in the form of a flexible rope for piston rod packing and for rope rings and gaskets, in moulded form for gaskets for pressure of 200 to 250 pounds, and in the form of convex and concave packing rings. A detailed price list is included for each case.

The Buffalo Forge Co., Buffalo, N. Y., has issued a 52-page catalogue which will prove of particular value to those engaged in the choice of equipment for industrial works. It is devoted to the Buffalo down-draft stationary and heating forges, containing illustrated descriptions of the various classes of this apparatus, together with data concerning blowers and exhausters for use with them.

The Sunlight Lava Mfg. Co., Chattanooga, Tenn., has issued a catalogue of acetylene gas burners. These are made of a solid piece of talc, designed to consume ¼ to 1 foot of gas per hour, except some small ones for bicycles, lanterns, etc.

To all lovers of the æsthetic in municipal betterment, the 1902 Year Book of the Municipal Art Society of New York will be found very interesting. The society has a number of committees on different work and all seem to have been quite aggressive and fairly successful. The lines followed have included signs and street fixtures, private advertising signs, parks, thoroughfares, and flowers, vines and area planting.

A good presentation of the subject of the purification of water for boilers has been prepared by D. W. & R. P. Patterson, Harrison Building, Philadelphia, including not a little of the chemistry involved. The work has been produced to show the advantages of the Bachman system of water purification, which they control, and describes in some detail the apparatus required for plants of less than 500-horse-power capacity and for those of 500 to 3,000 horse-power.

A new design of friction water-wheel governor, made to transmit, if necessary, 5,000 foot-pounds per second to the turbine gate, has been built by the Woodward Governor Co., Rockford, Ill. A feature of the governor, which is known as Size B, Compensating Type, Horizontal Model, is a device to provide that the gate is moved to that point which will give the correct speed after the momentum of the machinery has been overcome. The governor is described in a circular issued by the company.

Personal and Obituary Notes.

Mr. Herbert Conant has been appointed town engineer of Attleboro, Mass.

Mr. John B. Heim has been re-elected superintendent of the Madison, Wis., water-works.

Mr. Walter Brown has been elected county surveyor of Franklin county, Columbus, O., succeeding Mr. Henry Mætzel.

Mr. E. T. Perkins, of the U. S. Geological Survey, has charge of an engineering corps for irrigation study along the Colorado River from Needles to Yuma.

Mr. C. S. Brice, who several months ago succeeded Mr. J. J. Patterson as division engineer of the Montana Central Railway at Great Falls, Mont., has resigned.

Mr. Alten S. Miller, consulting engineer of the Consolidated Gas Co., of New York, has been appointed general manager of the Consolidated Gas Company of Baltimore.

Mr. J. K. Wilkes, formerly in charge of sewer construction in New Rochelle, N. Y., has been appointed chief engineer of sewers of that city, succeeding Mr. L. E. Van Etten, resigned.

Mr. James W. Johnson, for nearly 14 years city engineer of Riverside, Cal., has tendered his resignation in order to devote his time to other work which will take him out of that city.

Messrs. Elliott & Eaton have opened offices in the Keystone Building, Pittsburg, to practice general engineering, including the construction of coke plants, electric and steam railroads, foundations, buildings and bridges.

The Buffalo Chapter of the American Institute of Architects has elected the following officers: President, E. B. Green; first vice-president, H. O. Holland; second vice-president, R. A. Wallace; secretary, F. A. Whelan; treasurer, M. G. Beierl.

Mr. Emmett A. Gould, for thirteen years superintendent of the Eastern Division of the Wabash Railroad at Peru, Ind., has resigned that position to succeed Mr. Daniel Hardy as general superintendent of the Missouri Pacific Railway at St. Louis.

Mr. W. S. Henning, who has been resident engineer for the Houston & Texas Central Railroad for a number of years, has resigned to accept a similar position with the Southern Pacific Company and Mr. Hans Helland has been appointed as his successor, with headquarters at Ennis, Tex.

Mr. Thomas Appleton, M. Am. Soc. C. E., has been transferred from the construction department of the U. S. Life Saving Service to the office of the Supervising Architect of the Treasury Department and has been detailed to superintend the construction of the new post office at Creston, Ia.

Messrs. Norman B. Livermore & Co., who organized recently at 320 Sansome Street, San Francisco, to conduct a general engineering business, have been appointed Pacific Coast agents for the Wm. B. Scaife & Sons Co., of Pittsburg, for the sale of the water softening and purifying systems of that company.

Clarence E. Pullen, at one time surveyor general of New Mexico, died October 8 at Bangor, Me., aged 52 years. He was graduated from the Massachusetts Institute of Technology, began engineering in construction work on the Bangor & Aroostook Railroad and was afterwards connected with the Atchison, Topeka & Santa Fe Railway.

The New Jersey Chapter of the American Institute of Architects has elected the following officers: President, Herman Kreitler, of Newark; first vice-president, F. W. Wentworth, of Paterson; second vice-president, Robert C. Dixon, Jr., of Union Hill; secretary, Hugh Roberts, of Jersey City; treasurer, Thomas Cressey, of Newark.

Mr. Richard W. Sherman, M. Am. Soc. C. E., has received the Democratic nomination for the office of state engineer and surveyor of New York State. From 1866 to 1873 he was engaged in railroad engineering work, and since that time has largely devoted his time to municipal work, chiefly to the construction of water-works. In 1886 and 1887 he was engineer of Oneida county and only recently was mayor of Utica.

Mr. J. C. Irwin has resigned as engineer of signals of the New York Central & Hudson River Railroad, to enter the operating department. Mr. Peter G. TenEyck has been appointed his successor, and Mr. John Roberts succeeds Mr. TenEyck as supervisor of signals of the Middle Division. Mr. Thomas A. Lang has been appointed engineer of construction in the Pennsylvania Division, with headquarters at Mahaffey, Pa.

Capt. Eugene W. Van C. Lucas, Corps of Engineers, U. S. A., has been ordered to Memphis to relieve Captain E. E. Winslow, Corps of Engineers, of the duties in connection with the First and Second Districts of the Mississippi River improvements, and Capt. Winslow is to assume the duties performed by Capt. Lucas, with headquarters at Wilmington, N. C. Lieut. Lytle Brown, Corps of Engineers, has been assigned duty at the West Point Military Academy.

A New Meter Ordinance has recently been adopted in Madison, Wis., for the purpose of making landlords responsible for the water supplied to tenants. It reads as follows: "Water rents, when first collected for new buildings, or when water is first put in old buildings, shall be charged and collected as follows: The rent for the first semi-annual period, or for the part thereof remaining until the next first day of January or July proportionately, at the schedule rate and thereafter according to the quantity used, as shown by the meter. If at the end of said first semi-annual period the meter shows less water used than the amount paid would entitle the consumer to at regular meter rates, then the consumer shall receive credit for the difference on his next six months' water rent. In cases of change of tenants, where water rent is delinquent when a tenant moves out of a building, the water rent, so delinquent, shall be charged and collected from the owner of the premises and it shall be the duty of the superintendent to immediately notify such owner of such delinquency, and to shut the water off from the premises, and the water shall not be again turned on for such premises until the water rent, with penalty, is paid to the city treasurer."

Oiled Shell Roads have recently been constructed in Galveston, Tex., by methods which City Engineer C. G. Wells outlines substantially as follows: The subgrade of sand is first soaked with water and compacted by ramming. It is then covered to a depth of 9 inches, and rising about 2 inches above the finished surface grade, with a mixture of 80 per cent. rotten shells, 8 per cent. terra-cotta clay and 12 per cent. water. This is dredged from reefs in the Bay. It is allowed to stand until the surface is nearly dry, which usually occurs in about two days, and is then worked to grade with a 6-ton roller. Finally it is thoroughly sprinkled with crude oil, and a month later is again oiled. Oil costs 60 cents per barrel, and its total cost on the road is 0.56 cent per square yard, including labor. The amount of the other items of the roadwork is 31.5 cents per square yard. About 18,000 square yards of street have been surfaced in this manner, and after two months' service under heavy teams there has been no appreciable wear. If they hold up for a year, it is proposed to surface all unpaved streets in this way.

CONTRACTING NEWS

OF SPECIAL INTEREST TO

CONTRACTORS, BUILDERS, ENGINEERS AND MANUFACTURERS

OF ENGINEERING AND BUILDING SUPPLIES.

For Proposals see page xv, xvii, xviii and xxvii.

WATER.

Portland, Me.—The City Water Co. of Chillicothe, Portland, has been incorporated to build and operate water works. Capital, $175,000. Pres., E. Caswell; Treas., C. D. Booth, both of Portland, Me.

Bridgeport, Conn.—The Bd. of Aldermen has passed a resolution providing for the employment of a hydraulic engineer to investigate and report upon what plan should be adopted to improve the city water.

Portsmouth, N. H.—Water bonds to the amount of $50,000 were sold recently.

New Britain, Conn.—Chmn. Hall, of the Water Bd., is reported to have stated that plans for the new retaining reservoir in Wolcott call for a capacity of 140,000,000 gals, the cost to be $75,000. It has been decided not to begin construction until the spring.

Worcester, Mass.—The City Council has passed an order for a new dam at Leicester; estimated cost, $120,000.

Westminster, Md.—The Common Council has passed an ordinance accepting the proposition of the Citizens' Co. to furnish water for city purposes for $800 per year, and directing that a contract in accordance therewith be made.

Troy, N. Y.—Bids will be received Oct. 24 (readvertised) by the Bd. of Contract & Supply for erecting a gatehouse, with fixtures and appurtenances, and laying approximately 120 ft. of 20-in. cast iron pipe. John Phelan, Comr. of Pub. Wks.

Baltimore, Md.—The $1,000,000 water loan ordinance has been passed by both the First and Second Branches of the Council.

Lonaconing, Md.—A. M. Evans, Secy., writes that the Lonaconing Water Co. is about to construct a dam (contract not let) at a cost of $7,000.

Quogue, L. I., N. Y.—It is proposed to construct water works at a cost of $76,000, to supply this town, West Hampton Beach and East Quogue.

Canajoharie, N. Y.—It is understood that the Canajoharie Water Supply Co. has offered to sell its system, recently completed, to the village for $135,000.

Altoona, Pa.—Ordinances have been passed providing for water mains in several streets.

Salem, Va.—J. H. Palmer, Secy. Water Com., writes that said Com. has been appointed to ascertain the cost of sinking an artesian well to secure a better water supply. W. B. Dillard, Chmn. of Com.

Charleston, S. C.—Bids will be received Oct. 22 by the American Pipe Mfg. Co., Philadelphia, Pa., for erecting a pumping station. Plans may be obtained from Wm. C. Miller, 35 Broad St., Charleston.

Atlanta, Ga.—See "Sewerage and Sewage Disposal."

Summerville, Ga.—The coming Legislature will be petitioned by this village for authority to issue $25,000 bonds for the improvement of the water works and sewerage system.

Griffin, Ga.—Nesbit Wingfield, City Engr. of Augusta, is said to be making an investigation of the public needs of this city with special reference to the water works.

Tampa, Fla.—The Tampa Water Works Co. is said to be considering plans, prepared by Miller & Kennard, for the new water works plant which said company proposes to build. A pump of 4,000,000 gals. capacity per day will be installed.

Kewanee, Ill.—City Engr. J. E. Kemp writes that on Oct. 7 John M. Healy, Opera House Blk., Chicago, received the contract for furnishing pipe, etc., as follows: 8,500 ft. of 6-in. main in place, 92 cts. per ft.; 200 ft. 4-in. main in place, 73 cts. per ft.; 16 fire hydrants in place $26.50; five 6-in. valves and boxes in place, $17.

Montevideo, Minn.—E. A. Aspnes, Supt. Water Wks., writes that proposed new water works will cost about $15,000.

Columbus, O.—Bids are wanted Oct. 23 for furnishing the Water Works Dept. with 15 tons of pig lead. C. M. Addison, Clk. Bd. of Pub. Works.

Bloomington, Ill.—City Clk. C. C. Hassler writes that it is proposed to improve the water works, but no definite plans have as yet been made.

Marinette, Wis.—A correspondent writes that the American Water Works & Guarantee Co., of Pittsburg, Pa., contemplates lowering the 18-in. intake pipe across Menominee River at this point 5 ft.

Ruthton, Minn.—Bids will be received Nov. 3 by the Village Council for $3,000 water works bonds. Frank L. Nash, Village Recorder.

Shinnston, W. Va.—The Town Council is reported to be considering the question of constructing water works at a cost of about $12,000.

Lanesboro, Minn.—Bids will be received Nov. 3 by the Village Council for $6,000 water works and electric light improvement bonds. O. N. Viste, Village Clk.

Truman, Minn.—Bids will be received Oct. 28 by O. N. Steenstrup, Village Recorder, for constructing water works from plans of M. B. Haynes, of Mankato.

Westbrook, Minn.—Bids will be received by John E. Villa, Village Recorder, for constructing water works. M. B. Haynes, Engr., Mankato.

Kiester, Minn.—Bids will be received Oct. 30 by C. W. Tuebner, Village Recorder, for a cypress tank of 30,000 gals. capacity, and a 50-ft. steel tower to support the same.

Vinton, La.—The Hurd-Ford Inv. Co. writes that the Sabine Canal Co. contemplates the extension of its irrigation plant at a probable cost of $150,000.

Bessemer, Ala.—City Engr. Wm. J. Parkes writes the Council has ordered him to prepare plans and estimates for a complete system of municipal water works; water to be obtained from springs 3 miles distant; capacity of proposed works, 3,000,000 gals. per day. It is expected to be ready to begin construction by Jan. 1, 1903. Bonds to the amount of $200,000 have been authorized for this purpose.

St. Louis, Mo.—Engr. in Charge Ben. C. Adkins writes that an ordinance now pending provides for an appropriation of $15,000 for meters and $100,000 for sprinkling plugs.

San Saba, Tex.—A charter has been granted to the San Saba Valley Irrigation Co., with a capital of $360,000, to irrigate and place under cultivation a tract of several thousand acres in the valley of the San Saba River. Incorporators: John Kelly and John R. Cunningham, of San Saba County; Stephen D. Emmon, of Chicago, Ill., and others. Principal office, San Saba.

De Queen, Ark.—The City Council is stated to have passed an ordinance providing for the construction of water works.

Sherman, Tex.—This city has sold $45,000 water and sewer improvement bonds.

Sebree, Ky.—Press reports state that a water works system is to be built.

Guthrie, Okla. Ter.—A territorial charter has been granted to the Otter Creek Irrigstion Co. with the principal place of business at Mountain Park and with $1,000,000 capital.

Seattle, Wash.—H. A. Johnson, Town Clk. of West Seattle, has applied to this city for the extension of the Cedar River water supply to that town.

Fulton, S. D.—The question of issuing bonds for water works is under consideration.

Richfield, Utah.—This city has voted $14,000 bonds for a system of water works.

Caldwell, Idaho.—It is reported that bids will be received Oct. 26, at the office of the Pioneer Irrigation Dist., Caldwell, for completing the Phyllis Canal, requiring the removal of 187,500 cu. yds. of material, and for the completion of the Straborn Canal, requiring the removal of 66,400 cu. yds. of material. R. H. Davis, Secy.

Roswell, N. M.—The citizens of this place are considering the question of installing a system of water works.

Redlands, Cal.—City Clk. L. W. Clark writes that the question of municipal ownership of the water works is under consideration.

Sterling, Colo.—Town Clk. C. L. Goodwin writes that at a special election held Oct. 11 it was voted to construct water works at a cost not to exceed $63,000.

Renton, Wash.—The citizens are stated to have voted on Oct. 7 in favor of constructing water works.

Redlands, Cal.—The Oakglen Domestic Water Co. has been incorporated; principal place of business, Redlands; capital, $10,000. Directors: Isaac Ford and C. H. Sargent, of Redlands, and W. C. Lukens, of Oakglen.

La Junta, Col.—Bids will be received Nov. 1 by M. F. Miller, Secy. Bd. Dir. of the Otero Irrigation Dist., for $300,000 irrigation bonds.

Colorado City, Col.—This city is said to be planning to build a municipal water works.

Cando, N. D.—Local press reports state that this city has decided to install water works and sewerage systems.

SEWERAGE AND SEWAGE DISPOSAL.

Westfield, Mass.—Bids are wanted Nov. 5 for building Section 2 of the system of storm water sewers, as advertised in The Engineering Record.

Lenox, Mass.—At the town meeting Oct. 13 it is stated that $20,000 was appropriated for new sewers.

Brackenridge, Pa.—Bids will be received by T. A. Gallagher, Boro. Clk., until Oct. 20, for the construction of a two-ring brick sewer on certain streets; in all 3,488 ft. 4 ft. by 5 ft. sewer, with 6 manholes and 2 catch basins. Estimated cost, $20,000. E. E. Maurhoff, of Tarentum, Pa., is City Engr.

West Hoboken, N. J.—Town Surveyor Sebastian Maulbeck writes that plans have been completed for the proposed relief sewers.

Lower Merion, Pa.—The Lower Merion Township Comrs. have decided to borrow $250,000 for the construction of the sewer system.

Philadelphia, Pa.—The proposed construction, at the city's expense, of a new main sewer in Market St., under the ordinance recently introduced in Select Council, will save the Philadelphia Rapid Transit Co. the cost of that improvement, which has been roughly estimated at $175,000.

Bayonne, N. J.—Bids will be received Oct. 21 by the City Council for constructing sewers in three streets. W. C. Hamilton, City Clk.

Batavia, N. Y.—The Sewer Comrs. have presented to the Bd. of Aldermen their report, placing the estimated maximum cost of portion of sewer system proposed to be constructed at $375,000. Minimum cost, $300,000.

Etna, Pa.—Bids are wanted Oct. 24 for constructing a sewer on Vilsack St. and a portion of Wilson St. Geo. H. Jacob, Boro. Clk.

East Washington, Pa.—Bids will be received Oct. 21 by the Burgess and Council for $20,000 sewer bonds, also $30,000 paving bonds. Norman E. Clark, Secy.

Baltimore, Md.—City Engr. Fendall, in his estimated expenses for 1903, has incorporated an item of $94,500 for the construction of Sumwalt run sewer.

Saratoga Springs, N. Y.—The Bd. of Trus. has granted the application of the Sewer, Water & Street Comn. for an issue of $40,000 bonds, the proceeds to be used in the construction of a sewage disposal plant.

Roselle Park, N. J.—Bids will be received Nov. 8 by the Mayor and Council of Boro. of Roselle for constructing a sewerage system. A. M. Woodruff, Boro. Clk.

Perkasie, Pa.—An ordinance is before the Council granting to W. H. Davis and Harry T. Shelly, of Quakertown, and Grier Scheetz, of Perkasie, the right to construct and maintain a complete system of sewers in the Boro.

Bridgeport, Pa.—Plans and estimates are reported to have been prepared for a system of sewerage.

Easton, Pa.—Mayor Lehr in a recent message to the Councils, advocates the issue of $300,000 bonds to pay for needed improvements, such as additional sewers, street improvements, etc.

Pittsburg, Pa.—The Finance Com. favorably reported an ordinance providing for the construction of sewers in numerous streets.

Perth Amboy, N. J.—The Bd. of Aldermen is stated to have awarded a $55,000 sewer contract to Martin Hanson and Carl C. Christensen; there will be 1,200 ft. of 2x3-ft. brick sewer, 3,710 ft. 7-ft. and 1,350 ft. of ditch emptying into Staten Island Sound.

Atlanta, Ga.—The Council has adopted a resolution appropriating $500 for the purpose of paying an expert to confer with the City Engr. with a view to arranging plans for an improved sewer system. The Council has approved the proposition to issue $400,000 bonds for the extension of the sewer system, and a like amount for the improvement of the water works.

Summerville, Ga.—See "Water."

Norfolk, Va.—Guild & Co., of Chattanooga, have received the contract for establishing a sewerage system in Berkley for $23,000.

Cape Charles, Va.—The City Council has voted to employ an engineer to begin work on a sewerage system for this place.

Rock Island, Ill.—City Clk. H. C. Schaffer writes that it is proposed to construct new sewers in the southwestern part of the city, City Engr. W. Treichler's report to be ready in a few weeks.

Columbus, O.—Bids are wanted Oct. 30 for constructing sanitary sewers, as advertised in The Engineering Record.

Bids are wanted Oct. 23 for the construction of an 18-in. and 15-in. pipe sewer in Miller Ave.; bids are also wanted on the same date for the construction of a main trunk sewer in numerous streets, varying in size from 36 in. to 8 in. in diameter. C. M. Addison, Clk. of the Bd. of Pub. Wks.

Julian Griggs, Ch. Engr. Dept. of Public Improv., writes that a large amount of sewer construction is soon to be undertaken in this city, for which bonds have been authorized to the amount of $255,000. The largest diameter is 10.5 ft., and trenching machines will be required. As soon as these sewers are under way it is expected that an expenditure of $150,000 additional will be authorized for storm water relief sewers. The completion of the main trunk sanitary sewer will also probably be followed by the construction of about 10 miles of sanitary laterals.

Ottumwa, Ia.—Bids are wanted Oct. 20 for the construction of a portion of South Ottumwa trunk sewer. T. F. Keefe, Chmn. Street Com.

Glenville, O.—Local press reports state that the Council has awarded sewer contracts as follows: To the W. J. Townsend Co., Doan St., between Garfield and Massie, for $43,533; also Doan St., between Massie and the s. village limits, for $25,092; to Wm. Lehsm & Sons, Doan St., St. Clair to Garfield, for $22,005.

Troy, O.—John P. Force, of Columbus, is stated to have been engaged to prepare plans and make surveys for the proposed sewerage system.

Niles, O.—It is stated that bids will be received Oct. 29 by the Sewer Comrs. for constructing sewers, catch basins, etc., in Park Ave. and 2 other streets. W. Y. Sayers, Clk.

Youngstown, O.—It is stated that bids are wanted Oct. 25 for constructing sewers in Inglis St. and Himrod Ave. C. E. Cross, Clk.

Cincinnati, O.—Bids are wanted Oct. 27 for constructing sewers in portions of Central Ave. Robert Allison, Pres. Bd. of Pub. Service.

Lake Charles, La.—This city has employed John W. Maxcy, of Houston, Tex., to prepare plans, specifications and estimates for sewerage, sewage disposal and pavements, estimated to cost $250,000.

Bessemer, Ala.—City Engr. Wm. J. Parks writes that the Council has ordered additional storm sewers, ranging in size from 18 in. to 42 in., to be built in the 2d Ave. Dist., at an estimated cost of $7,500. This work will be let about Nov. 4.

Topeka, Kan.—A petition is being circulated for the creation of a sewer district to include Dennis & Martin's addition, Orchard Place and Walnut Grove. Estimated cost of building sewers, $50,000 to $100,000.

Vermilion, S. D.—City Auditor C. I. Vaughn writes that the contract for constructing sewers in Dist. No. 1 (bids opened Oct. 6) has been awarded to Eric Nylen, of Vermilion, as follows: Pipe sewers, per lin. ft., 12 in., 89 cts.; 18 in., $1.24, and 8 in., 70 cts.; manholes, $55 each; catch basins, $47 each; trench to average 9 ft. in depth.

Lincoln, Neb.—This city will build about $6,000 worth of lateral sanitary sewers, all work to be done by day labor under the supervision of City Engr. Geo. L. Campen.

Tacoma, Wash.—City Engr. Taylor is reported to have about completed surveys for the proposed Edison trunk sewer. The sewer is designed to furnish sanitary drainage for the 6th addition, South Side addition, and the entire Edison Dist.

Revillo, S. D.—It is stated that bids are wanted Oct. 23 for constructing 12-in. sewers. John Elstad, Town Clk.

Loveland, Colo.—The Bd. of Town Trus. has established Sewer Dist. No. 1, extending the entire length of the town.

Cheyenne, Wyo.—The contract for constructing Warren Ave. sewer extension is reported to have been awarded to Frank S. Joslin, of Cheyenne, for $7,827.

Columbus, Neb.—Bids will be received Oct. 28 by G. W. Phillips, Co. Clk., for deepening and widening the Carrig & Jewell drainage ditch in Lost Creek and Shell Creek Township; approximate number of cu. yds. of earth to be removed, 31,000.

BRIDGES.

Bridgeport, Conn.—Local press reports state that the question of constructing a new bridge over Ash Creek, connecting Bridgeport and Fairfield, is under consideration. Probable cost, $25,000.

Reading, Pa.—The Berks Court has approved the building of 8 county bridges to cost $20,000.

Raymertown, N. Y.—According to plans and estimates prepared by Prof. Leslie Allen, of Albany, the cost of a bridge across the proposed Tomhannock reservoir, would be $65,000.

Connersville, Pa.—G. L. Potter, Gen. Mgr. of the B. & O. R. R., Baltimore, Md., is said to have approved plans for a bridge at their yards at Connersville.

Nutley, N. J.—The Nutley Bridge Com., of the Bd. of Freeholders, John F. Clark, Chmn., will erect a stone arch bridge over Third River at Franklin Ave.

Washington, D. C.—See "Miscellaneous."

Cumberland, Md.—The City Council has passed an order requesting the Baltimore & Ohio R. R. to place an overhead bridge across the tracks at Baltimore St.

Scranton, Pa.—Provision is made in the bond issue now pending in the Common Council for the erection of a steel bridge across Lackawanna River at a cost of about $29,000. The bridge is to be located either at Race St. or Sanderson Ave.

Neshanic, N. J.—The Somerset County Bd. of Freeholders, Somerville, has decided to rebuild the West bridge, near Neshanic; a low truss iron structure has been decided upon. Thos. E. Gibson, Chmn. of Com.

Port Perry, Pa.—Ch. Engr. W. H. Brown, of the Pennsylvania R. R., has awarded the contract to the Pittsburgh Construction Co. for the erection of a steel double-track railroad bridge, about 1,000 ft. long, main span 407 ft. long, over Monongahela River, at Port Perry. The bridge is to be completed within 8 months, and will cost approximately $550,000 in addition to the masonry.

Sanatoga, Pa.—It is stated that a bridge to cost about $30,000 will be constructed over the Schuylkill, at Sanatoga, Montgomery Co., to be paid for by Chester and Montgomery Counties. (Norristown, C. H.)

Spray, N. C.—The Rockingham Co. Comrs. are stated to have decided to appropriate $3,000 toward constructing a bridge over Smith River at Spray. (Wentworth, C. H.)

Huntington, Ind.—The County Council has made appropriations for the following county bridges: $14,000 for bridge over Salamoni River at Warren; $9,000 for bridge over Wabash River, south of Huntington, and $6,000 for a bridge over Wabash River north of Andrews.

St. Paul, Minn.—The Bd. of Aldermen has passed a resolution directing the City Engr. to prepare plans for the construction of the east end of the 3d St. bridge over the railway yards. Appropriation, $65,000.

Minneapolis, Minn.—The Council Railroad Committee has ordered the Northern Pacific R. R. Co. to build a bridge over its tracks on Harvard St. and one over the street at Como Ave., where the Como-Interurban tracks cross the railroad.

Indianapolis, Ind.—Local press reports state that the Virginia Ave. viaduct will be repaired by the Indianapolis Union Ry. Co., as soon as the approval of Pres. J. McCrea, whose headquarters are in Pittsburg, can be secured.

Bids are wanted Nov. 6 for the construction of a bridge over Little White Lick Creek, on road running north from Bridgeport. John McGregor, Comr. of Marion Co.

Akron, O.—The Northern Ohio Traction Co. has awarded the contract for constructing a $60,000 bridge across Cuyahoga River to the King Bridge Co., of Cleveland. Paul & Henry, of Barberton, O., will do the stone work and grading. E. D. Eckroad, Engr. in charge.

Winnebago, Minn.—The County Bd., Blue Earth City, is stated to have decided to erect a bridge across Blue River, south of Winnebago.

Streator, Ill.—Petitions are being circulated asking that the City Council take steps toward the construction of a bridge at the foot of Main St., across Vermilion River.

Vincennes, Ind.—Edw. C. Faith is said to have prepared plans for a bridge, consisting of three spans of 140 ft. each, piers of stone and concrete, to cross White River.

Chicago, Ill.—Local press reports state that the bridge over the river at Archer Ave. and 31st St. is to be replaced by a steel structure of the bascule type, to cost $200,000.

Traverse City, Mich.—A press report states that Blomshield & McCloy are preparing plans for a combination concrete and steel bridge for Traverse City. The structure will be 100 ft. long and 66 ft. wide, and will carry double railway tracks. The bridge will have 16,000 pounds per lin. ft. capacity.

Hamilton, O.—The Miami & Erie Canal Transportation Co. and the Cincinnati, Hamilton & Dayton Traction Co. (C. G. Waldo, Mgr., Cincinnati) are reported to have decided to erect a bridge over the canal at Dayton St.

Utica, Mo.—Ernest Allen, Fred. Sherman and others are said to be interested in the construction of an iron bridge over Grand River, north of the town. Cost about $4,000.

Arkadelphia, Ark.—The Clark County levying court has voted in favor of building a steel bridge across Ouachita River, between Arkadelphia and Daleville.

Topeka, Kan.—Bids are wanted by the Comrs. of Shawnee Co., S. H. Haynes, Chmn., until Nov. 10, for the erection of a 60-ft. low truss steel bridge, tubular piers, with 32-ft. approach, to cross Missouri Creek, in Dover Township. John M. Wright, Co. Clk.

Memphis, Tenn.—The proposed stone and iron overhead bridge to cross the tracks at Dunlap St., will, it is estimated, cost $10,000; the railroad companies interested will probably pay seven-eighths of said cost.

De Queen, Ark.—The Sevier Co. Comrs. at Lockesburg, are stated to have decided to appropriate $5,000 for a bridge over Rolling Fork River, west of De Queen.

Ellendale, N. Dak.—Co. Aud. H. J. Oberman writes that the contract for constructing a 250-ft. steel bridge across James River, has been awarded to Wm. S. Hewett & Co., of Minneapolis, Minn., for $7,896.

San Jose, Cal.—Co. Surveyor J. G. McMillan has been ordered to prepare plans and specifications for bridges over Llagass Creek, on San Martin Ave., Rucker Ave. and Llagass Ave., Road Dist. No. 1.

Spokane, Wash.—A joint bridge is to be built over Hangman Creek by the city and the county. Total cost, $36,000; the county has agreed to appropriate $14,000.

Tiburon, Cal.—Citizens of this place have petitioned the Co. Bd. of Supervisors, San Rafael, to appropriate $5,000 toward the construction of a bridge to span the channel of the lagoon at Tiburon. Total estimated cost, $8,000.

Lexington, Neb.—Co. Clk. J. T. Costin writes that $12,000 bonds were voted Sept. 25 for the construction of a bridge across Platte River.

Tempe, Ariz.—The Maricopa County Bd., Phoenix, Ariz., is said to be considering the construction of a bridge over the river at Tempe.

Chippewa, Ont.—Bids are wanted by Norval B. Hagar, Allenburg, Ont., Chmn. of Road & Bridge Com. of Welland County, until Oct. 21, for supplying material and building abutments, center piers and guards, and superstructure for a steel swing bridge across Welland River at Montrose, 4 miles from Chippewa; length over all, about 190 ft.; length of swing, 110 ft.; fixed span, 80 ft., with clear roadway of 16 ft.; concrete piers and abutments. Geo. Ross, of Welland, Ont., Engr.

Hilo, Hawaii.—Bids are wanted Oct. 31 for furnishing and erecting 2 steel bridges, one over Walakea River, 100 ft. span, pin centers, and one over Wailuku River, 170 ft. span, pin centers, both bridges to have 20-ft. roadway and 2 4-ft. sidewalks. Jas. H. Boyd, Supt. of Pub. Wks.

PAVING AND ROADMAKING.

Fall River, Mass.—Both branches of the City Council have voted to authorize an additional highway loan of $40,000.

Boston, Mass.—Bids will be received Oct. 22 by James Donovan, Supt. of Streets, for constructing portions of Bennington St., in East Boston. A check of $5,000 is required with bids.

Springfield, Mass.—The City Council has passed the order providing for the extension of Court Sq. to the river.

Washington, Pa.—J. M. McAdam writes that 168 separate bids were received Oct. 6 for 38,712 cu. yds. of grading and 116,946 sq. yds. of paving, with brick and hill-side block; R. T. Hallam & Sons, of Washington, Pa., received the contract for paving 28 of the streets; Park Paving Co., Philadelphia, received 10 streets, and Wm. Pickett & Co., of Washington, received 2 streets. Bids of successful bidders averaged about $1.28 per yd., with a range from $1.23 to $1.30 for limestone bed. Grading was let at 28 cts. to 32 cts. per yd.

Allentown, Pa.—Bids will be received Oct. 21 by the Mayor, Fred. E. Lewis, for paving portions of 2 streets with Trinidad Pitch Lake, Bermudez Lake or Alcatraz sheet asphalt.

Buffalo, N. Y.—Bids will be received Oct. 25 by Wm. H. Daniels, Co. Treas., for $70,000 Erie Co. good roads bonds.

Syracuse, N. Y.—The Syracuse Improvement Co. is stated to have received the contract for paving with standard brick in Butternut St. from North Salina St. to the city line, for $61,591.

West Hoboken, N. J.—Sebastian Maulbeck, Town Surveyor, writes that 5,700 sq. yds. of bituminous macadam waterproof pavement is to be laid.

Washington, D. C.—See "Miscellaneous."

Brooklyn, N. Y.—Bids are wanted Oct. 23 for repairing and repaving with asphalt on old asphalt foundation the walks in Prospect and Ft. Greene Parks. Wm. R. Willcox, Comr. of Parks.

Bids will be received Oct. 29 by J. Edw. Swanstrom, Boro. Pres., for improving numerous streets; the work includes 70,880 sq. ft. cement sidewalk, 10,370 sq. yds. asphalt pavement, 9,960 sq. yds. macadam pavement, and 5,900 sq. yds. granite pavement.

Trenton, N. J.—Bids are wanted Oct. 21 for repaving S. Broad St. with sheet asphaltum over Belgian block. C. Edw. Murray, City Clk.

New Brighton, S. I.—Bids will be received Oct. 24 by Geo. Cromwell, Boro. Pres., for repaving with asphalt block on concrete foundation, portions of Broadway. Engineer's estimate, 2,800 sq. yds. asphalt block pavement; 470 cu. yds. concrete, including mortar bed, and 1,700 lin. ft. new curbstone furnished and set on concrete foundation.

Buffalo, N. Y.—The contract for paving with brick on Sobieski St. has been recommended for award to Wm. H. Kinch for $5,913.

Washington, D. C.—The Commissioners have been requested by the East End Suburban Citizens' Assoc. to include in their estimates to Congress an item of $25,000 to continue the improvement of Bladensburg Rd., $5,000 for the repair of that road and $200 for resurfacing Park St.

Baltimore, Md.—The Municipal Bd. of Estimates has received a proposition from the U. S. Wood Preserving Co., offering to pave North Ave. with wooden blocks, for $470,000, the estimate being as follows: 139,814 sq. yds. to be paved, $433,423; new curbing, $17,040; old curbing reset, $1,125; old headers, $1,125; new cobble, $494; old cobble, $895; grading, $11,031.

Auburn, N. Y.—City Engr. Ackerman estimates the cost of proposed paving as follows: 12,707 yds. of sheet asphalt paving at $1.97 per sq. yd.; cost to city, $23,600; the Auburn City Ry. Co.'s share would be $1,432; total cost of brick pavement between railway tracks, $2,158.

New York, N. Y.—Bids are wanted Oct. 22 for the following work in the Boro. of Bronx: Paving with granite block in several streets, about 79,255 sq. yds.; asphalt paving in several streets, about 21,735 sq. yds., and asphalt block paving in several streets, about 24,200 sq. yds.; also grading, setting curbstone, etc., in E. 181st St., work to include 18,250 cu. yds. of rock excavation, 36,050 sq. ft. of new flagging, etc. Louis F. Haffen, Pres., Boro of Bronx.

Newark, N. J.—The Essex Co. Freeholders are about to begin the construction of a public speedway, to be 1 mile long and 150 ft. wide, on the outskirts of Newark; cost not to exceed $50,000, including the purchase price of the right of way.

Canandaigua, N. Y.—The Ontario County Bd. of Superv. has voted to improve 30 miles of highways in accordance with State regulations; cost, $259,000, the State paying half.

New York, N. Y.—The following bids were opened Oct. 14 by J. A. Cantor, Pres. Manhattan Boro., for repaving with asphalt and granite on present pavement and concrete foundation Park Ave. from 111th St. to 133d St.: A, Century Constr. Co.; B, Barber Asph. Pavg. Co.; C, Asphalt Constr. Co.; D, Sicilian Asphalt Pavg. Co.:

Bidders.	Asphalt, 61,200 sq. yds.	Granite blk., 2,400 sq. yds.	Old stone relaid, 61,500 sq. yds.	Concrete, 400 cu. yds.	New curb, 7,600 ft.	Old curb, 1,900 ft.	Manhole covers, 73.

D. Wood & Co., Philadelphia, Pa., $94,540.

NEW INDUSTRIAL PLANTS.

The Ideal Heating Co., Oskaloosa Ia., is erecting a 30x44-ft. molding room, and will be in the market for a 1,200 to 1,600-lb. cupola and a blower.

The Alexander Furnace & Mfg. Co., Lansing, Mich., is erecting a 2-story, 72x75-ft. shop, and intends to install a gas engine of about 20 H.-P. The company will be in the market for shafting, pulleys, belts, elevator, emery grinder and drill press.

The Dublin, Ga., Machine & Wagon Co. will erect a 35x80-ft. machine shop and a 35x100-ft. wagon shop. The company is in the market for an engine of about 60 H.-P. and 80-H.-P. boiler.

The Pioneer Flouring Mill Co., Island City, Ore., will probably erect a 150 to 200-bbl. mill, run by water power, to replace that recently burned, and install an auxiliary engine.

The Hall Signal Co., 25 Broad St., New York, has let a contract for the extension of its 3-story machine shop, at Garwood, N. J., 100 ft., which will make the size of the building 250x60 ft.

The F. S. Walton Co., 136 So. Front St., Philadelphia, has let contracts for the erection of a plant for pressing, refining and shipping animal oils, which will include a 100x40-ft. press house and refinery, with bleaching tanks on top; 40x26-ft. cold-storage plant; 20x40-ft. engine house; 20x40-ft. boiler house; 24x40 and 40x60-ft. shipping houses and a 105x20-ft. cooper shop. No contracts for equipment have been let.

The Russell & Erwin Mfg. Co., New Britain, Conn., intends to erect a 7-story, 175x50 ft. addition and install a 750-H.-P. engine.

James W. Woods, 64-66 Queen St., Ottawa, Can., maker of lumbermen's supplies, will erect a 6-story, 70x140 ft. factory.

R. S. Hill, president of the Farmers' and Merchants' Bank and the Farmers' Loan & Trust Co., Anderson, S. C., contemplates erecting a 25,000-spindle cotton mill to be driven by steam.

The London, Ont., Fence Machine Co., Ltd., has secured a site for a branch plant in Cleveland, O.

The Red Wing, Minn., Linseed Mills, has been incorporated with a capital of $100,000 and intends installing a 6-press mill for the present. N. K. Simmons, Pres.

The Burrows Mfg. Co., York, Pa., intends to erect a large plant for making steam specialties, which will probably not be erected before next spring or summer.

The Union Grain & Hay Co., Cincinnati, O., intends beginning about Jan. 1 to erect a 150,000-bu. elevator.

The Binner-Wells Co., 21-25 Plymouth Court, Chicago, will erect an 8-story, 50x120-ft. building. The capacity of the power plant will be 100 H.P., and motors will be installed.

J. L. Lovvorn, Bowdon, Ga., is interested in the organization of a company to erect a cottonseed-oil mill.

Robt. L. Steele, Rockingham, N. C., has bought a cotton mill building at Mammoth Spring, Ark., and intends to install new machinery.

BUSINESS NOTES.

The New York Continental Jewell Filtration Co., 15 Broad St., New York, reports the following among recent contracts: Water-works filter plants for Pontiac, Ill., Light & Water Co.; Freeport, Ill., Water Co.; Carthage, Mo., Water Co.; Danville, Ill., Water Co.; Camden, S. C., Water, Light & Ice Co.; U. S. Government, Presidio, San Francisco, Cal. Water-softening plants for the Cincinnati, Lawrenceburg & Aurora El. St. Ry. Co., North Bend, O.; Lackawanna Iron & Steel Co., Lebanon, Pa.; Columbia Chemical Co., Barberton, O.; Calumet & Hecla Mining Co., Lake Linden, Mich.; Chicago & Eastern Illinois R. R. Co., plants at Villa Grove, Holland, Salem, Marion, St. Elmo, Benton and Cypress, Ill.

Sargent, Conant & Co., Boston, will shortly complete the electric power and lighting equipment of the Hampton Co., Easthampton, Mass. The entire plant will be electrically driven, current being supplied by two multiphase generators, one direct coupled to a Corliss type engine, and the other belted from a water wheel, either or both of which can be used for operating motors, are or incandescent lamps.

The Snider-Hughes Co., Cleveland, O., builders of pumping machinery, have commenced the erection of a new plant, to include an 80x200-ft. machine shop, 36x60-ft. power house, 50x100-ft. pattern and storage building, and 38x45-ft. office building, and expect to erect a 60x150-ft. foundry in the spring. Two 100-H.-P. boilers, a 125-H.-P. engine and a 500-light dynamo, which have been bought, will be installed.

The Ball Engine Co., Erie, Pa., reports recently receiving orders from the following: Osborn, O., Water & Light Co.; Vose Piano Co., Boston, Mass.; Grand Crossing Tack Co., Chicago.

The New England Structural Co., Boston, has contracted to furnish in four months the steel framework for the new India Building, Boston, comprising 1,300 tons. Peabody & Stearns, Archts.

The Rhode Island Suburban Ry. has revised its contract with the Green Economizer Co., increasing the order to five complete machines.

The Alberger Condenser Co., 95 Liberty St., New York, reports the following among orders recently received: Belt Light & Power Co.; Pennsylvania Sugar Refinery; Sharon Steel Co.; Port Huron Light & Power Co.; Hartford Street Ry. Co.; Binghamton Light, Heat & Power Co. The equipment for the above plants consists of Alberger barometric or surface condensers with improved vacuum and circulating pumps, and the necessary appurtenances for producing the high vacuum required by the use of steam turbines which are being installed in most of the above plants.

The annual meeting of the stockholders of the Sprague Electric Co. was held Oct. 14, at the office of the company in Watsessing, N. J., and the following directors were elected for the ensuing year: Allan C. Bakewell, D. C. Durland, S. M. Hamill, J. R. Lovejoy, John Markle, J. R. McKee and E. G. Waters. At a meeting of the directors held later in the day, officers were elected as follows: Pres., Allan C. Bakewell; 1st Vice-Pres., S. M. Hamill; 2nd Vice-Pres., D. C. Durland; Sec. and Treas., Harry R. Swartz.

The Allis-Chalmers Co. has just sublet to the Coffin Valve Co. a contract for large sluice gates to be used in connection with the new Chicago sewerage plant. Two of these gates are 11 ft. in diameter, heavily bronze mounted, and are to be operated by hydraulic cylinders, and there are also included in the contract two check valves of 9 ft. diameter.

Reconstruction of a Stone Dam at Roswell, Ga.... 401

The Engineering Record, conducted by Henry C. Meyer, is published every Saturday at 21 Park Row, New York. Its opinions on technical subjects are either prepared or revised by specialists.

Subscriptions are received and single copies supplied by the International News Company, Breams Building, Chancery Lane, London.

The subscription rate is $5 a year for the United States, Canada and Mexico, and $6 for other countries in the Postal Union. Remittances should be made by check, New York draft or money order in favor of The Engineering Record. No responsibility is assumed for payments made otherwise, except those for subscriptions to the International News Company.

General and Separate Contracts.

The growth of engineering projects to the enormous dimensions prevailing at the present time in many works, both public and private, has naturally led to the most complicated conditions in tendering for the contracts and in the execution of the work after the award of contracts. This development in the execution of large structural enterprises has not only necessitated the use of great mechanical plants, far beyond anything considered practicable a comparatively few years ago, but it has also made unavoidable either the consecutive or the concurrent performance of different classes of work, many of them differing radically in character. These various classes of materials and structural operations in the same completed whole emanate from different sources and require different treatment and plant, yet they must be so handled and conducted as to contribute harmoniously to unity of plan, both in construction and in the final results. This diversity of elements in modern great constructions has become so marked that it is a matter of much moment to many civil engineers whether one general contract should be made to cover all the component parts of such works, or whether separate contracts should be arranged to cover the different portions, each of which would be executed under those conditions of specialization which have contributed so effectively to excellence in all branches of modern structural operations.

This broad question has already been actively discussed by both engineers and engineering contractors. In some prominent engineering circles, the consensus of opinion as expressed has been largely in favor of separate contracts, and yet there may be conditions under which that judgment, even when assumed to be mainly correct, may be wisely modified. The main difficulty arising in connection with general contracts covering a number of classes of special work is due to the fact that one contractor seldom has had experience in more than one line of operations or in one given line and those lines closely affiliated with it. Furthermore, one contractor usually does not possess the requisite plant for different classes of structural operations. When, therefore, he is obliged to tender for a general contract, he finds himself compelled to seek prices from others for the materials and the labor which he is unable to furnish or perform. As there are ordinarily a number of general bidders in the field who must secure the same set of prices, competition becomes somewhat demoralized. The general contractor is uncertain as to the reliability of his prices, excepting those based on his own material and labor. He frequently is unable to secure from sub-contractors figures to which they can be held, and he is never certain whether he may not ultimately have to pay more than he contemplates, or whether he may not be able, by a fortunate turn of the market or for some other reason, to secure lower prices than those named. Under such conditions, it may, on the one hand, be a legitimate business risk to use lower prices than those furnished, or, on the other hand, it may be necessary to guard against prospective adverse market developments by increasing the prices quoted by sub-contractors.

A comprehensive view of these circumstances indicates that in either event they are not such as favor economy in construction. In the one case, the contract price may include an unreasonably large profit, or, in the other, the margin may be insufficient, tempting the contractor to make exertions to save himself from loss. Neither result would contribute to the excellence of the work nor to the peace of the supervising engineering organization.

These are considerations which have a most important bearing on the administration of contracts for great engineering works and which are many times insufficiently recognized. It seems plausible to the owner, whether private or public, to execute a general contract for the entire work, thus dealing with one party only and apparently avoiding what may seem like petty details connected with different portions of the project. This trend of opinion is frequently encouraged by the engineer, under the same view of the case. As a matter of fact, however, it is rare that the engineering supervision is relieved by such a procedure; indeed, there is little or no reason why it should be. The duty of the engineering organization is to see that every portion of the work is constructed and put in place with the degree of excellence required by the contract and specifications. It really makes no difference with the engineering supervision whether the separate sub-contractors are recognized in the general contract or not; the work of each must be carefully scrutinized and each must be dealt with in actual construction to all intents and purposes as if he were formally recognized in the general contract, although the general contractor only be held directly responsible. It is a matter of serious doubt, therefore, whether the amount of trouble attending the execution of the contract is reduced to any extent below that which would be entailed by a number of separate contracts. It may be argued that experience has shown the difficulty of securing schedule completion of different, separately contracted portions of a large work and that serious friction and even lawsuits may result when that is not accomplished. While there may be some slight basis for such observations, the difficulties mentioned may be reduced to small dimensions by tact and good management. As a matter of fact, schedule completion of work is just as necessary under one general contract as under a number of separate contracts, and practically the same good management and tact are required in both cases. It is a question whether the owner does not eventually have about as much trouble in the one case as in the other.

Again, wherever sub-letting by a general contractor occurs, it is not infrequent that he realizes large profits on his sub-contracts that would have been saved to the owner had tenders been made for separate portions of the work. This is particularly true of large public works, one of which now in progress is a most marked instance of this kind.

Under certain circumstances there may be material modifications of the conditions outlined above, although such exceptions are probably more likely to exist in the future than in the present. General contracting firms or contracting syndicates for large and special projects are intended to include organizations and plants adapted to the supplying of all material and the performance of all labor required under a general contract. In such cases there is obviously no lost motion, nor channels for diversion of profits to those who do not perform the work. As a business proposition it would seem to be most judicious, and, in the long run, most satisfactory to both parties to award a contract to those who are to execute it; and it is believed that public corporations or municipalities will in the end find that procedure to lead to both the highest degree of economy and to the greatest excellence.

Elsewhere in this issue is printed a valuable discussion on this subject recently presented to the American Society of Civil Engineers.

State Supervision of Sewerage Work seems to be feared by many engineers in Ohio, who believe they see a menace to the satisfactory design of sewer systems in a bill now before the legislature requiring that a copy of the plan for any sewer "with a certified copy of the ordinance of the Council approving and adopting such plan shall be forwarded to the State Board of Health, and the said ordinance shall not be valid until approved by the said State Board of Health." Such legislation ought to be prevented. The State Board of Health is very properly given the right of veto in all matters relating to sewage disposal, not only on sanitary grounds but also because the control of methods of disposal by a State Board tends to prevent the injury of several communities by the improper disposal of the sewage of a single town. But the control of the sewer network by such a board can have no useful result and will simply wrap red tape around purely engineering matters, thereby causing delay and tending to produce friction between officials whose work should be carried on harmoniously.

American Appreciation of American Anthracite is an ancient subject for British jokes, and the English engineer is always ready to assert that Americans are sure, when the last trump is blown and the universe perishes in fire, that a little unconsumed remnant will survive which analysis will show to be Pennsylvania anthracite. Mr. Charles H. Haswell, the veteran engineer still practicing his profession although ninety-four years old, has recently explained what may have been the first enunciation of this quip. When he was a boy some alleged coal was mined in Rhode Island by a company organized for the purpose, and samples distributed to well-known New Yorkers for test. One of them, Martin S. Wilkins, gave his opinion as follows: "I am willing to certify that, under favorable circumstances, this coal is capable of ignition; and I am willing further to certify that, if Rhode Island is underlaid with such coal, at the general conflagration which our ministers predict, it will be the last place to burn." This Rhode Island coal, it may be said, has been the cause of the loss of much money, and the same is true of the coal in the part of the Blackstone valley in Massachusetts, where, in one place at least, a large sum was spent to open a colliery furnishing material which would burn only under a blowpipe.

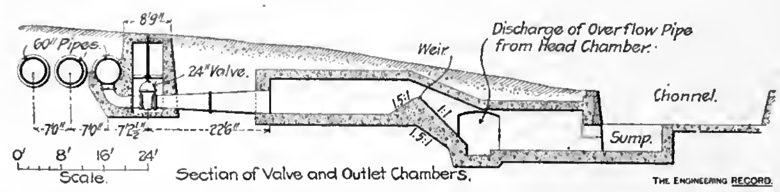
The Weston Aqueduct of the Metropolitan Water-Works, Boston—II.

By Alfred D. Flinn, Engineer, Designing and Drafting Department.

Headworks.—The headworks of the aqueduct might have been designed somewhat differently if the plans for them had been drawn before the construction of the Sudbury Dam, but this dam was begun in 1893 and completed in 1898. The middle part of the dam, for a length of 300 feet, is of solid masonry, built on the ledge rock, and serves as a waste weir for the discharge of surplus water from the reservoir. Its cross-section was outlined in The Engineering Record of November 4, 1893. At one end of this masonry portion of the dam, adjoining the earth embankment, a gate chamber was formed on the up-stream face and three 48-inch cast iron pipes laid through the bottom of the dam, in the masonry, to a 55-foot diameter circular basin just below the toe of the dam and in the spillway through which the water flows to the brook. The pipes ended in three quarter curves which turned up through the bottom of this basin so as to discharge the water vertically. Of course the purpose in turning the discharge upwards and allowing the water to fall back into the masonry basin was to dissipate the force due to the great head and thus prevent erosion of the brook channel. Incidentally the large jets which issued, if the gates were opened to any considerable extent, formed an imposing fountain. From the basin all water coming through the pipes, as well as all that spills over the top of the dam, flows away in the old brook channel to Framingham Reservoir No. 3, and thence through pipes or channels to the Sudbury Aqueduct, which conveys it to the Chestnut Hill distributing reservoir in Boston.

The head chamber, at which the 10-foot diameter masonry portion of the Weston Aqueduct begins, is located on the hillside near the northerly end of the dam, with its invert 25 feet above the bottom of the brook channel. The old masonry is being removed from around the ends of the 48-inch pipes, and the quarter curves will be taken off. Connections will be made by means of increaser castings and the pipe lines continued as three 60-inch lines to the head chamber. At a convenient place four 24-inch side outlets are provided on each of two of the 60-inch lines, through which water may be discharged at will into the brook channel to flow to the reservoirs below and thus supply the Sudbury Aqueduct. Each 24-inch outlet is controlled by a 24-inch valve, and beyond the valves the pipes are increased in diameter, at the rate of one inch per 10.6 inches of length, to a diameter of 48 inches at the ends. The pipes are thus flared in order to reduce the velocity of the water at the points of discharge so that it will not do damage and at the same time to take advantage of the Venturi principle to increase the discharging capacity of the pipes.

These eight outlet pipes end in a concrete outlet chamber, one side of which is parallel to the 60-inch pipe lines and the other coincident with the northerly side wall of the brook channel, the angular difference of about 51.5 degrees between the directions of the pipe lines and the channel being overcome in the chamber, as shown in the diagram. The outlet chamber is roofed with concrete 18 inches thick reinforced with 1½-inch round steel rods having 8-inch square steel washers on their ends, and is covered with earth. A partition wall divides the chamber so that water from four pipes flows each side. Each half is divided into a low level and a high level part by a round crested concrete weir with the center of its crest 8 feet from the end of the pipe at one side of the chamber and 27 feet at the other side. The crest is 3 feet above the bottoms of the pipes. The purpose of the weir is to cause the water to completely fill the large ends of the pipes and to further check the force of the jets. The floor of the lower part of the chamber is 5 feet below the bottom of the brook channel. The water will issue through four arches of 10-foot span into a depressed rectangular basin 12x46 feet, formed in the bottom of the channel, and overflow into the channel. The soffits of the arches at the crowns are 4 inches below the level of the bottom of the channel, so that the openings will always be sealed by the water standing in the depressed basin, or sump. The space above the weir is drained by two 6-inch pipes, without valves, laid through the weir so that at times when no water is flowing through the large outlet pipes they will be empty and can be entered as far as the 24-inch valves without shutting down the 60-inch mains. During any considerable flow from the large pipes, however, the quantity passing through the 6-inch pipes will not be sufficient to have any material effect.



Outlet from Pipe Lines of Head Works to Channel Leading to Lower Reservoirs.

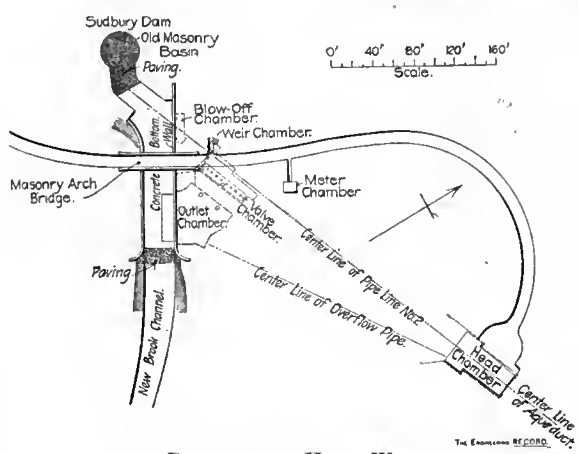


Diagram of Head Works.

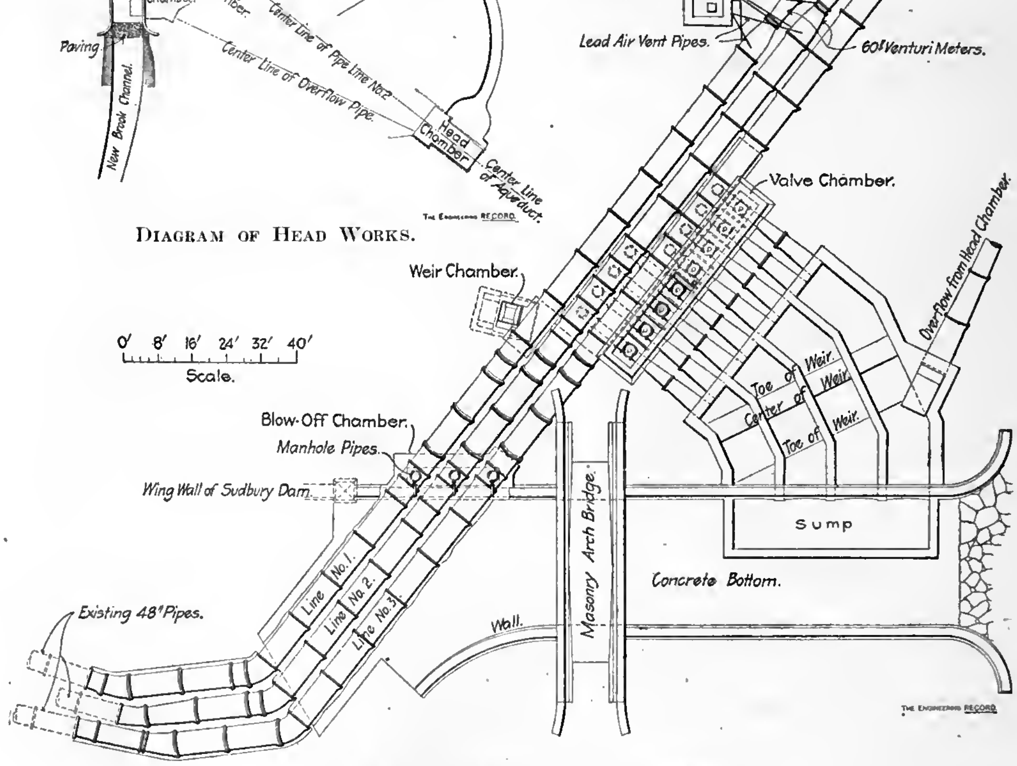


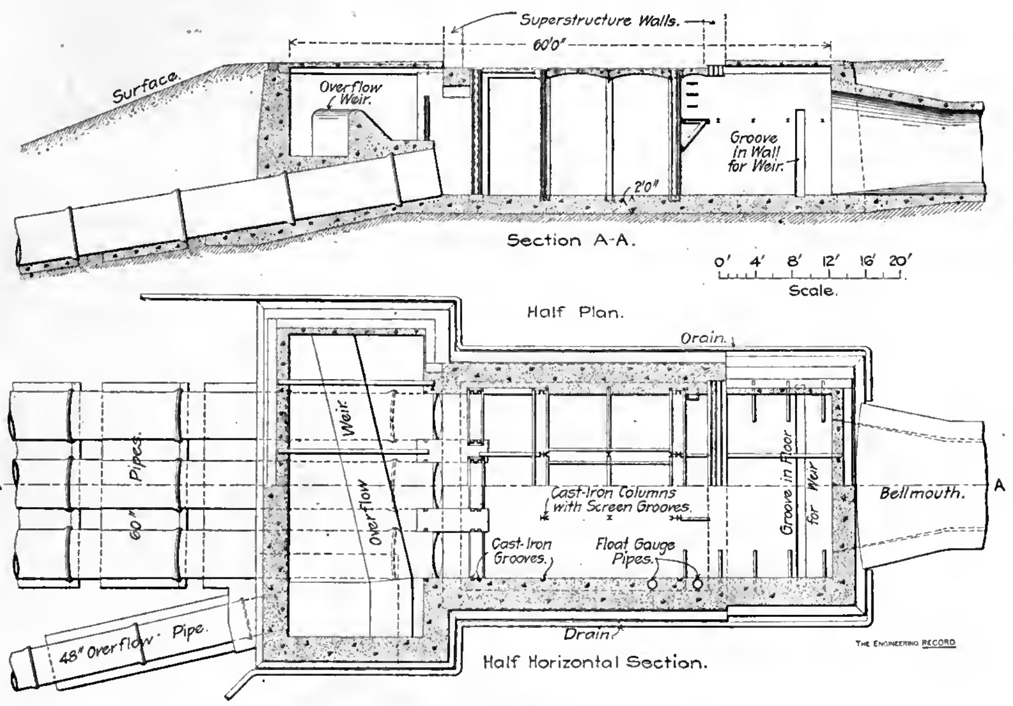
Head Works, excepting Head Chamber.

The brook channel is to be relocated, paved and walled from the dam to a point about 20 feet downstream from the outlet chamber, and for the remaining 1,600 feet to Reservoir No. 3 is to be rectified and improved to such extent as may be necessary. The old circular masonry basin is to be done away with, since there is no longer any need for it.

In the 60-inch pipe line which has no 24-inch side outlets and in one of the two which have there are two 60-inch Venturi meters made by the Builders' Iron Foundry, of Providence, R. I. A small building will be erected near the meters, for the registers. These registers are fitted with the new chart recorders, attachments designed to register the rate of flow on a band of slowly traveling paper which is ruled to indicate millions of gallons per day. A roll of paper will last a month, and the record may be torn off daily or at such intervals as may be desired. The paper is 3½ inches wide, and a 24-hour record is 8 inches long. Figures printed along the bottom of the chart indicate the hours of the day. The meter tubes are 32 feet 7½ inches long and consist of five pieces each, with bell and spigot joints, excepting the two flanged joints at the throat. The diameter of the throat is 38 inches. By the usual method of rating, on the basis of 36 feet throat velocity, the maximum capacity of these meters is 185 million gallons per day each, which is greater than that of any other meter in this country. The Jersey City water-works have a 72-inch meter with 31-inch throat. There are two 93½-inch Venturi meters in London, but the writer does not know their throat diameter.

There are no valves in the main pipes between the Sudbury Dam and the head chamber. The flow from the reservoir into these pipes and through them to the aqueduct will be controlled by the gate-house on the dam. The size of the main pipes was determined by balancing the cost of pipes against the value of water stored in the reservoir, and they are large enough to draw considerable quantities at very low stages of the reservoir. Consequently at the higher stages of the reservoir which ordinarily obtain, the capacity of the three pipes greatly exceeds that of the aqueduct.

The substructure of the head chamber is 66 x27 feet, but only the central portion, 31x29 feet, is to be covered by the superstructure. The part of the substructure in front of the superstructure is an overflow well, beneath which the three 60-inch pipes enter the chamber on a rising grade. Three arched openings over the pipes, in the wall of the chamber through which they enter, give access for the water to the overflow well. A round-crested concrete weir extends diagonally nearly across the well and then bends and continues to the front wall. The crest is 34 feet long and at such an elevation that a depth of 3 feet over it will cause a head of not over 3 feet on the soffit of the aqueduct arch just beyond the head chamber. This provides for an overflow at the rate of about 230 million gallons per day. Any water which may flow over the weir will fall into a channel which terminates in a deep well formed in the concrete, from which a 48-inch pipe leads to one corner of the outlet chamber at the brook. At the outlet chamber the overflow pipe increases at a rate of one inch per 10.6 inches to a diameter of 72 inches, for the purpose of reducing the velocity and taking advantage of the Venturi effect for increasing the discharge. If the gates at the dam are always properly manipulated, there should never be any use for this overflow, but to guard against ignorance and carelessness, as an extreme precaution, and because of the importance of the situation, it has been provided.



Head Chamber.

The head chamber contains grooves for stop-planks to make it possible to enter any one of the 60-inch pipes while the others are in use, and other grooves for vertical screens so placed that the screens can be arranged in re-entrant bays in order to give a greater area than would be afforded by a set of screens directly across the chamber. The screen grooves are iron castings. Some of them are embedded in the masonry of the walls, but those at intermediate points are combined to form columns to support the steel beams of the main floor. For the immediate future, however, until the usual rate of flow in the aqueduct shall become about 150 million gallons per day, it is intended to use inclined screens. In the row of stop-plank grooves 11 feet in front of the ends of the 60-inch pipes, a plank bulkhead 6 feet high will be placed, and from the top of this the supports for the screens will slope upward one foot in 6 to within 16 feet of the back of the chamber. Such screens have been in use for a number of years at the Farm Pond gate-house of the Sudbury Aqueduct and can be cleaned ordinarily by a push broom, without removing them, as the water tends to accumulate the leaves, twigs, grass and other rubbish at the high water line on the screens. If at times leaves or other things clog the screens, or for any reason it becomes necessary to remove the screens, each one can be taken up easily, being only 37x38 inches in size. The screens are to be made strong enough for a man to walk upon them, the copper wire netting being supported by wooden ribs ½ inch wide and 2¾ inches deep spaced 5 inches apart.

In the underground extension of the chamber at the rear of the superstructure a measuring weir is to be installed, which, like the inclined screens, will probably be maintained until such time as the ordinary flow in the aqueduct reaches 150 million gallons per day. The weir is intended to provide an additional means for measuring the water to check or supplement the Venturi meters and the current meters.

A driveway leads from the main highway to the Sudbury Dam, and is to be extended along the toe of the dam, up the hillside to the head chamber. Where this driveway crosses the brook channel a masonry arch bridge of 30 feet span and 6 feet rise is being built to replace an old bridge which has been removed. The bridge will be 14 feet wide between railings and built of Portland cement concrete, mixed 1:2:5 in the arch and 1:4:10 in the abutments, with facings and copings of gray granite. The crown thickness is to be 18 inches, and the granite facing, excepting the headers and voussoirs, is to be only about 12 inches thick. The waste channel, along the toe of the masonry portion of the Sudbury Dam, through the bridge and as far as the downstream end of the outlet chamber, is to be paved and walled with masonry excepting where sound ledge is exposed. The channel has a depth of 6 feet below the springing line of the bridge arch, and the passage through the bridge is calculated to be large enough to safely pass a flow equivalent to a run-off of 4 inches from the watershed above the dam.

Contractors' Plant.—On many of the sections of cut-and-cover work, the contractors' methods and equipment have no especial interest, being the ordinary hand operations with pick and shovel, horse and cart, and very little machinery. Messrs. Winston & Company, however, have installed some plants which are innovations in this class of work and worthy of description. Crushing, screening and mixing machinery, with the necessary engines and boilers, have been assembled in a very compact way near the middle of a stretch of aqueduct and tracks laid to bring materials from the pits and carry concrete to the forms, mules being employed to haul the cars. On Section 11 a 7-ton locomotive is also in use. There are three similar plants, on Sections 8, 11 and 15.

The plant on Section 11 is the largest, and a description of it will give the essential features found in all. There is a No. 5 Austin stone crusher near the ground level discharging into a belt-and-bucket conveyor, which elevates the broken stone to a rotary screen at the top of a tall wooden structure. From the screen the stone passes by gravity into storage bins, and the rejected large pieces are returned to the crusher. Near the top of the structure, also, are some large, inclined, stationary screens for sand and gravel which likewise discharge into suitable storage bins and send the rejected stones to the crusher. The bins are at a sufficient elevation to discharge by gravity into cars or carts beneath or onto an elevated measuring platform. To reach the bins above the measuring platform, however, the sand and gravel have to be elevated by the conveyor. A large mast and boom derrick fitted with a bull wheel has been set up conveniently near a corner of the structure where it can reach the skips of gravel, stone and cement brought on the cars and deliver them to the crusher, the screens or the measuring platform, as desired. There is a small platform attached to the mast about six feet above its base, where the operator stands who controls all the movements of the derrick. In the middle of the measuring platform is a large, conical, steel measuring hopper with a dropping bottom controlled by a latch, and with its top flush with the surface of the platform. The hopper empties into a cubical concrete mixer immediately below it, and the mixer in turn can be dumped into cars or carts which pass beneath. Three men are employed on the measuring platform, and there is an inspector here, and one man takes care of the mixer. Several charges of cement in bags are kept on the platform during the day. The stone for concrete is measured in the hopper, into which it is discharged directly from the storage bins by gravity, through a chute. The proper number of bags of cement is emptied on to the stone and spread over it. The sand is drawn from the bin into a measuring box, hung on trunnions, which, when filled, is tipped so as to dump its contents into the hopper. The sand is spread over the cement with shovels, and then the charge is let into the mixer. It has been found that spreading the sand promptly on top of the cement saves considerable loss of cement, especially in windy days. The water is measured in a small cylindrical steel tank, fitted with a gage glass, and admitted to the concrete mixer through its perforated hollow shaft, gradually from the beginning of the mixing. This water tank is beneath the measuring platform. The mixer is revolved from 25 to 35 times, and each batch contains about 32 to 34 cubic feet of concrete. The capacity of the concrete cars is 44 cubic feet. The capacity of the plant is estimated to be about 200 cubic yards of concrete per day, but so far the conditions of the work have never been such as to realize this output. An 80-horse-power return-tubular boiler, which is fired mostly with wood, supplies steam for the three engines, one for the derrick, one to revolve the concrete mixer and the third, of 25-horse-power, to operate the main part of the plant.

In constructing aqueduct by this method, as used on Section 11, the side embankments are first built up and the cuts made so that the place for the construction railroad can be graded and the rails laid very close to the edge of the trench. The cars are used also for moving the excavated materials. The track is laid at about the level of the springing line of the arch, and when a piece of trench or embankment is ready for concrete, dumping platforms are placed at frequent intervals to receive the concrete from the cars. For the invert the concrete is shoveled into chutes which deliver it by gravity to the bottom of the trench, where it is spread by shovels and brought to proper form by the aid of guides and screed boards. After the invert has set, the forms for the side walls are placed in position and the concrete deposited in them from wheelbarrows loaded at the dumping platforms. For this operation, foot boards are laid across and along the aqueduct in circuits from each dumping platform so that the men always go forward and do not have to return or get in one another's way. Having constructed a sufficient stretch of side walls to keep well ahead of the bricklayers, who place the brick lining in the invert and sides, the concrete gangs set the arch centers and forms, where the brick lining has been completed, and build the arch.

On Section 8 twelve men at the trench have placed as much as 130 cubic yards of concrete in the invert in one day, and the same gang has built 100 linear feet of arch, which requires 100 cubic yards of concrete, in a day. Much difficulty is experienced in screening sand in damp weather because the sand adheres to the wires and tends to clog the screens. Sand for the brick work is rescreened by hand through finer screens.

On Section 15, which includes rock tunnel number 5 and a great deal of rock excavation in trench, an air compressor plant was established at the east end of the tunnel and the concrete plant erected near by.

Steel Siphon Pipes.—The four siphon chambers which form the connecting links between the steel pipes and the masonry aqueduct were shown and described in the article of May 4, 1901. Other details of the pipes and chambers are shown in the accompanying illustrations. At the crossing of the Sudbury River, the pipe will be given the form of an arch with a span of 80 feet and a rise of 5.5 feet between substantial, granite-faced, concrete masonry abutments. The vertical reversed curves adjoining the arch are to be imbedded in the concrete of the abutments and have 6x6-inch steel angles riveted to them circumferentially and longitudinally to anchor them the more securely. All seams in the arch are to be double riveted and all rivet holes drilled. A light wooden foot bridge with iron pipe railings is to be attached to the top of the arch by means of short pieces of steel angle. A similar arch of about 164 feet span and 11.5 feet rise, in a pipe line of very nearly the same diameter, was built across the Arc River, in France, in 1897, and is described and illustrated in "Le Genie Civil" for June 23, 1900.

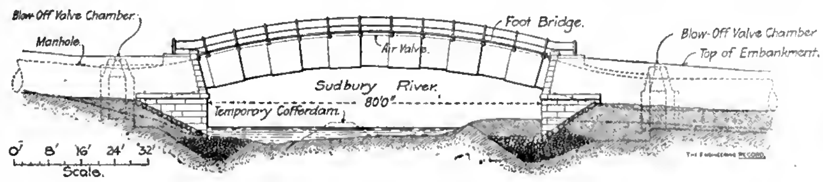
Plant for Laying Steel Pipes, Happy Hollow Siphon.

Castings at Siphon Chamber for Connecting with Steel Pipes.

The 7½-foot steel pipes for the siphons are being made in 30-foot lengths of four plates each, excepting for some curves, in alternate large and small courses. The plates are 7/16 inch thick, excepting for the arch of pipe which is to span the Sudbury River, in which they are ⅝ inch thick. All plates are basic open hearth steel containing not over .5 per cent. manganese, and .05 per cent. phosphorus, sulphur and silicon; having a tensile strength of not less than 52,000 nor more than 62,000 pounds, and an elastic limit of not less than 30,000 pounds per square inch; an elongation of not less than 25 per cent. in 8 inches, and a reduction of area of not less than 50 per cent. The Central Iron and Steel Co., of Harrisburg, Pa., is rolling the plates and the Pittsburgh Testing Laboratory is inspecting them. The plates average about 91 by 290 inches in size, and the 7/16-inch plates weigh about 3,500 pounds each. The plates are shipped from the mill on covered flat cars, teamed to the shop, unloaded under cover, and kept under cover until the pipe is ready for testing. All rivets are 1-inch Victor rivets, with conical heads, made by the Champion Rivet Co., of Cleveland, Ohio.

In the shed where the plates are unloaded, they are first prick-punched, then beveled and then heated for scarfing. The prick-punching for the rivet holes is done from steel plate templates. The edges on both sides and ends are beveled by means of a rotary beveling machine made by the Lenox Machine Co., of Marshalltown, Iowa, which at one operation for each edge, whether it is the straight edge of a regular piece or the curved edge of a special, removes a sufficient strip of metal to make the distance from the rivet holes to the edge uniform and bevels the edge to about 60 degrees. The two corners to be hammered down thin for the lap are heated simultaneously in two small forges, and then the plate is passed immediately into the adjoining shop to the blacksmiths. After being scarfed, the plates are punched and rolled and then passed to the riveting shop, where they are assembled into 30-foot sections of pipe of four plates each, except in the case of specials for curves. Hydraulic riveting machines with vertical jaws are used capable of exerting a pressure of about 80 tons on each rivet. There is a man to operate the riveter and a boy to heat rivets outside the pipe as it is being assembled, and a man and a rivet boy inside the pipe. The boy outside throws heated rivets into a box sunk in the floor beneath and extending outside of the pipe, and the boy inside, standing on the floor, takes the rivets from the box and passes them to the man, who inserts them into the rivet holes from the inside. The plates are cut so correctly to dimensions and the punching is so accurately done that the holes usually match perfectly and very little reaming is necessary.

All calking is done with pneumatic tools. After calking and inspection, the pipes are rolled to the testing stand and subjected to a water pressure of 75 pounds per square inch. Trolley tracks supported by a timber frame, on each side of the testing stand, carry two sets of testing heads, so that one pipe may be filling while another is being tested. The water is pumped and after being used drains back to the pump well to be pumped over again. The test heads are ¾-inch dished and flanged plates in one piece, provided with manholes and pump and gage connections. They are held in place in the pipe by pins and bolts through the flange and the rivet holes in the ends of the pipe.



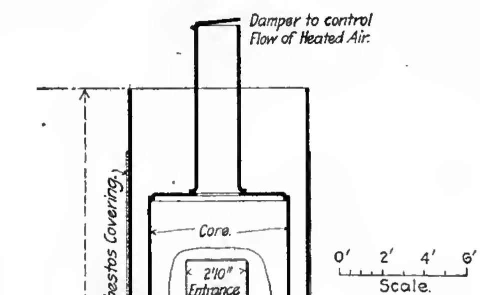
Sudbury River Pipe Arch Bridge.

They are made tight by calking inside with oakum. Similar heads are to be used for testing portions of the pipe lines after they shall have been laid.

From the testing stand the pipes are rolled to the dipping tower and immersed vertically in a bath of Mineral Rubber pipe coating manufactured by the Commercial Asphalt Co., of New York. The bath is heated to a temperature of 500 to 550 degrees Fahrenheit, as determined by a pyrometer inserted at the top of the tank. The pipes are not previously heated, but are left in the dip twenty minutes or more so as to attain the temperature of the bath. Immersing a cold pipe drops the temperature of the bath only about 30 degrees. A very satisfactory coating is being obtained, which is especially smooth on the inside of the pipe. It is about 1/32 to 3/64 of an inch thick and adheres tenaciously to the steel. The dipping tank is shown in one of the illustrations with sufficient clearness to need no explanation. Heat is applied to the full height of the dipping tank through the core, or inner cylinder, and, in addition, to about half its height through the jacket, or outer cylinder. The jacket was not provided at first, but was added because it was found difficult to maintain the proper temperature at the bottom of the bath. The tank is covered with asbestos, as shown, and enclosed in a wooden tower about 35 feet square at the base and 80 feet high. A hand traveling crane in the top of the tower lifts the pipes from a horizontal position on the floor, lowers them into the tank and holds them there. A pneumatic cylinder attached to the side of the tower about 20 feet above the ground is used to trip the bottoms of the pipes when they are being lowered from the tank and aid in placing them in a horizontal position on the skids. Petroleum gas made on the premises is used for heating the dipping tank and in the rivet and scarfing forges.

The finished pipes are carried from the shop to the railroad on high, flat wagons and loaded on to flat cars provided with bolsters. At the railroad destination the pipes are placed on special wagons and hauled to the trench. These wagons measure 20 feet from center to center of axles, and have 6-inch tires and heavy running gear supporting four pieces of 7x8-inch spruce, which form the bed, and on which there are bolsters and triangular blocks covered with split rubber-lined hose, rubber side out. The top of the wagon is nearly on a level with the top of a flat car, but the front is a few inches higher than the back. Six horses are hitched to the wagon.

On Section 9, the greater part of which is on the steep grades of the hillsides of the narrow valley, the pipes were unloaded at the trench on to a wooden incline, the higher end of which was at the level of the top of the wagon, and rolled down on to a small steel-framed car running on a track laid along the bottom of the trench. A hoisting engine and an air compressor were located at the bottom of the valley. The pipe on the car was hauled into position by the hoisting engine and a wire cable working through a pulley at the top of the incline. Jacks were used to elevate the downhill end of the pipe so as to bring the rivet holes at top to correspond with those of the pipe previously laid and permit a bolt or two to be inserted, and then the car was withdrawn and the pipe lowered, with the jacks, until the joint was brought to a fit all around. The same method is being used on Section 7. The car frame is provided with rollers, upon which the pipe lies and which permit it to be revolved so as to adjust the rivet holes. Field riveting is done by means of a heavy pneumatic riveting machine inside the pipe, mounted at the intersection of vertical and horizontal extension braces which are attached to a plate and



Dipping Tank for Steel Pipes.

screwed out to bear firmly against the pipe. The holding-on is done with a pneumatic cylinder mounted in a stiff steel frame, which is connected into two chains that encircle the pipe. The chains are supported, so that they do not touch the pipe, by rubber-bound iron wheels, about 8 inches in diameter, the axles of which pass through the chain. The field joints and places abraded by transportation and other operations are promptly covered with Gilsonite paint, made by the Commercial Asphalt Company.

Mr. Frederic P. Stearns, M. Am. Soc. C. E., is Chief Engineer of the Metropolitan Water and Sewerage Board, and Mr. Horace Ropes is Engineer of the Weston Aqueduct Department. Messrs. Dan. B. Clark, Frank E. Winsor, Marshall Nevers and George W. Booth are division engineers.

Single-Phase Alternating-Current Electric Railway Operation.

The interurban electric railway, which the Washington, Baltimore & Annapolis Railway Company is to operate at high speeds with a single-phase alternating current equipment throughout, from generating station to driving axle, was described at some length in The Engineering Record of September 20. At that time no details were at hand as to the character and construction of the motor to be used nor any extended account of the method of its control. Since then, however, a paper on the subject has been presented to the American Institute of Electrical Engineers by Mr. B. G. Lamme, under whose supervision the system has been developed and tested for several years by the Westinghouse Electric & Manufacturing Company, and from this the following additional information has been obtained:

The type of motor to be used is similar in general construction to a direct-current series motor, but with its magnetic circuit laminated throughout and with such proportions that it can successfully commutate alternating current. The problem was to provide a single-phase motor having the variable speed characteristic of a direct-current series motor, such as is now in use for electric traction, the limitation to a single phase making more than one trolley line unnecessary. For the regulation of voltage, instead of the direct-current rheostatic series-parallel controller, an induction regulator, resembling an induction motor in general appearance and construction, is employed. This acts as a transformer, the secondary winding, which is placed on the stator, being connected to the motors and the voltage in the secondary, and consequently that supplied at the motors, being varied by shifting the angular position of the secondary in relation to the primary or rotor.

Single-phase alternating current will be supplied to the car at a frequency of 16⅔ cycles per second, or 2,000 alternations per minute. The current from the overhead trolley wire is normally fed in by one trolley at approximately 1,000 volts. Within the limits of the District of Columbia two trolleys are employed, as by Act of Congress the use of rails as conductors is prohibited in this District. The range of voltage at the motor is to be varied from approximately 200 volts up to 400 volts or slightly higher. The transformer on the car will supply 315 volts, and the secondary circuit of the regulator will be wound to generate slightly more than 100 volts when turned to the position of its maximum voltage. This voltage of the regulator is about one-fourth of that of the motors at full voltage. The regulator can consequently be made relatively small, in comparison with the motor capacity of the equipment.

There will be four motors of 100 horse-power on each car. The full rated voltage of each motor is approximately 220 volts. The motors are arranged in two pairs, each consisting of two armatures in series, and two fields in series, and the two pairs are connected in parallel. That is, the fields are arranged in two pairs, with two fields in series and two pairs in multiple. This parallels the fields independently of the armatures.

The Rio Grande Bridge of the Pacific Railway of Costa Rica.

The people of the United States are particularly interested at this time in their near neighbor, the Republic of Costa Rica, on account of the building of the Interoceanic Canal. The population of Costa Rica is composed, in the main, of small farmers, who own their lands. The soil is particularly rich and fertile, the principal products are coffee, bananas, cocoa, rubber and lumber. The coffee and bananas are considered the finest in the world, and command the highest prices in the American and European markets.

The country is far from being opened up, owing largely to the present poor facilities for transporting merchandise to the east coast. A large proportion of this merchandise is exported, and considerable is imported by way of the Pacific coast, notwithstanding that the only means of transportation at present is the slow-going ox cart, at a cost of $1.60 per cwt. The fact that hundreds of these primitive conveyances can be seen daily on the national highway between the Pacific coast and the interior is more than sufficient to demonstrate to even a casual observer the great advantages that will accrue to the country and its commerce by the completion of the Interoceanic Railway, as nearly all the principal towns and villages, and all the mining camps and centers, with fully two-thirds of the population of the entire country are situated on the Pacific slope.

In connection with this matter, it is of interest to state that the present tariff of the Atlantic Railway from Port Limon to San Jose is as follows: $19.78 American gold per ton, first class; $17.90 American gold, second class; $12.43 American gold, third class, for a haul of about 100 miles. The passenger tariff is four cents per mile.

The Pacific Railway of Costa Rica is needed, and, when completed, will be 60 miles long. It will extend from San Jose, the capital of the republic, which is connected by rail with the Atlantic coast, to the Pacific coast, passing through the richest and most thickly populated section of the country. This connecting line will give easy and quick communication between the Atlantic and Pacific coasts. It is located about 60 miles north of the Nicaragua canal route and, when completed, will be the only trans-continental line south of the Southern Pacific Railway, although another line is now under construction by the Mexican Government and its bridges are being built by the contractors for the bridge described in this article. The gauge of the road is 3½ feet, with a maximum grade not exceeding 2½ per cent. through the mountain district. The total cost of the road, when completed and equipped, will be $3,000,000.00 American gold. The government has paid, up to April 1, 1902, $1,126,925.75 American gold, in cash, and has issued a corresponding amount in bonds.

The road is now completed and in operation from San Jose to a point 20 miles beyond the Rio Grande River crossing, a total distance of about 46 miles. The grading and masonry is also finished for some distance beyond this point, and includes all the heavy and mountainous work. There are a few small bridges, but the great obstacle to be overcome was the crossing of the Rio Grande River. At the particular point where this crossing was made, it required a bridge approximately 685 feet long, with the rails not less than 340 feet above the water.

The height alone is not unprecedented, and the span, although considerable, has been exceeded by many recent structures. The combination, however, of length of span and height is remarkable and is exceeded by only two structures, the Garabit Viaduct and the Mungsten Bridge. A third bridge, that across the Noceschlacht valley at St. Giustans in the Tyrol, which is probably the highest in the world, is 453 feet above the water, but has a span of only about 197 feet.

A comparison between the Rio Grande River bridge and the Birriz viaduct, also in Costa Rica, shows in a very striking manner the radical difference in design and erection of two structures in the same locality and under similar conditions which were built by foreign engineers of different nationalities. The Birriz viaduct has four 156-foot single-track lattice-girder deck spans supported on three iron towers from the bottom of a valley about 200 feet deep. The spans were erected in the axis of the bridge on a level platform beyond one abutment, and when two of them were completed they were fastened together to make a continuous structure and were projected across the abutment on rollers until the pilot trusses 54 feet long, which were temporarily attached to the advance span, engaged rollers on top of the first pier and took bearing there. The second and third spans were successively erected and connected to those previously built and the increasing mass was pulled across the valley by a wire rope and windlass on the opposite abutment, the pilot successively engaging the rollers on the pier tops and farther abutment.

The Rio Grande River bridge is of special

THE RIO GRANDE RIVER BRIDGE.

interest as being the latest and probably the largest span in Central America, and on account of the location and conditions, as well as many difficult engineering problems connected with its dimensions and design. Realizing the many difficult engineering problems connected with a cantilever-arch bridge the railroad company did not attempt to directly undertake its construction, but placed the order for all the steel work with the export department of Milliken Brothers, No. 11 Broadway, New York, and the entire work was executed by them. They called in consultation Mr. Theodore Cooper, who, in conjunction with Mr. Gunvald Aus, M. Am. Soc. C. E., made all the calculations.

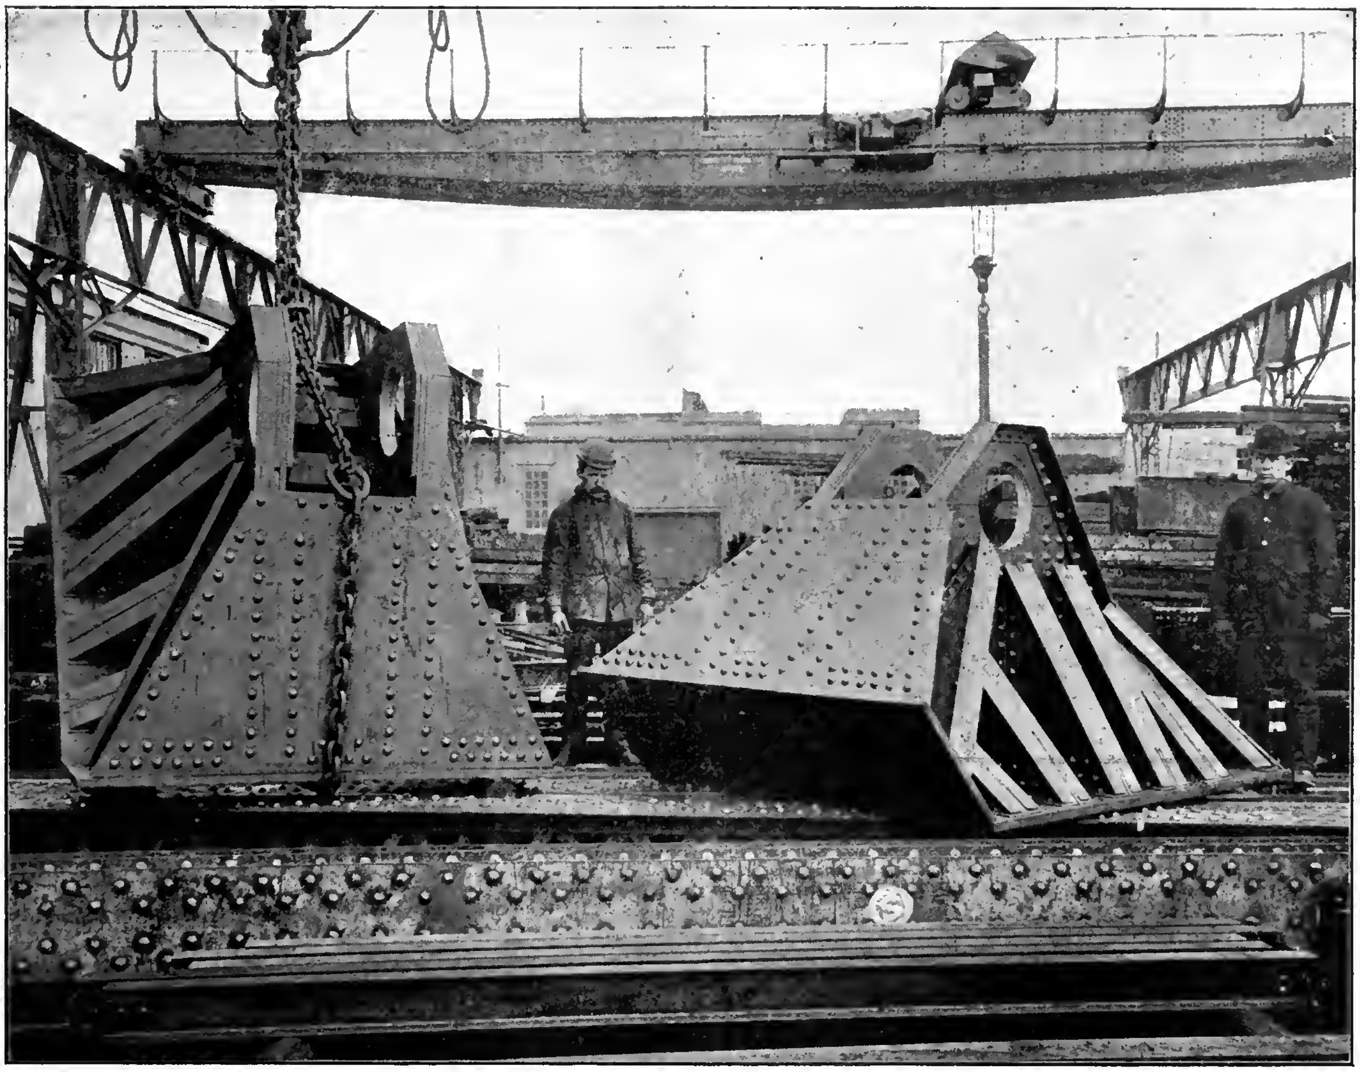
It was decided to adopt a design calling for a riveted truss single-track deck bridge, consisting of a two-hinge spandrel braced arch with eighteen 24-foot 10-inch panels, making a span of 448 feet 8¼ inches center to center of skewback pins, two cantilever spans, each with two 23-foot 7½-inch panels, and two 70-foot 10½-inch suspended shore spans, making a total length between end pins at the abutments of 684 feet 11¼ inches.

The bridge is designed under Cooper's Specification for a live load of 2,800 pounds per linear foot of span, and a dead load of 3,000 pounds per foot of span. The top lateral system is proportioned to resist a stationary wind load of 150 pounds per foot of bridge. The moving wind load is assumed to be transmitted through the sway bracing into the bottom lateral system, so that this latter is proportioned for a stationary wind load of 150 pounds per linear foot of bridge, and a moving wind load of 300 pounds per foot of bridge. The three panels at each end were formed into supported spans, to prevent the possibility of any hammering at the abutments.

The braced arch was originally figured in strict accordance with the method given in Professor Greene's book on arches, using the general formula first presented by Professor Clerk Maxwell. On account of a change in the distance between piers the arch had to be refigured and a modified method was used which had in the meantime been developed by Mr. Cooper. The modification consisted in developing the formula for H for two symmetrical panels and summarizing them, thus obtaining a very simple formula by which formulæ could be immediately written for all the remaining panels. The modified formula suggested economic proportions of depth to length of span and saved a great amount of labor in computations. As no greater range of temperature variations occurs in Costa Rica the temperature stresses were calculated for a difference of only 70 degrees, but even this amount made them form a very considerable percentage of the total stresses.

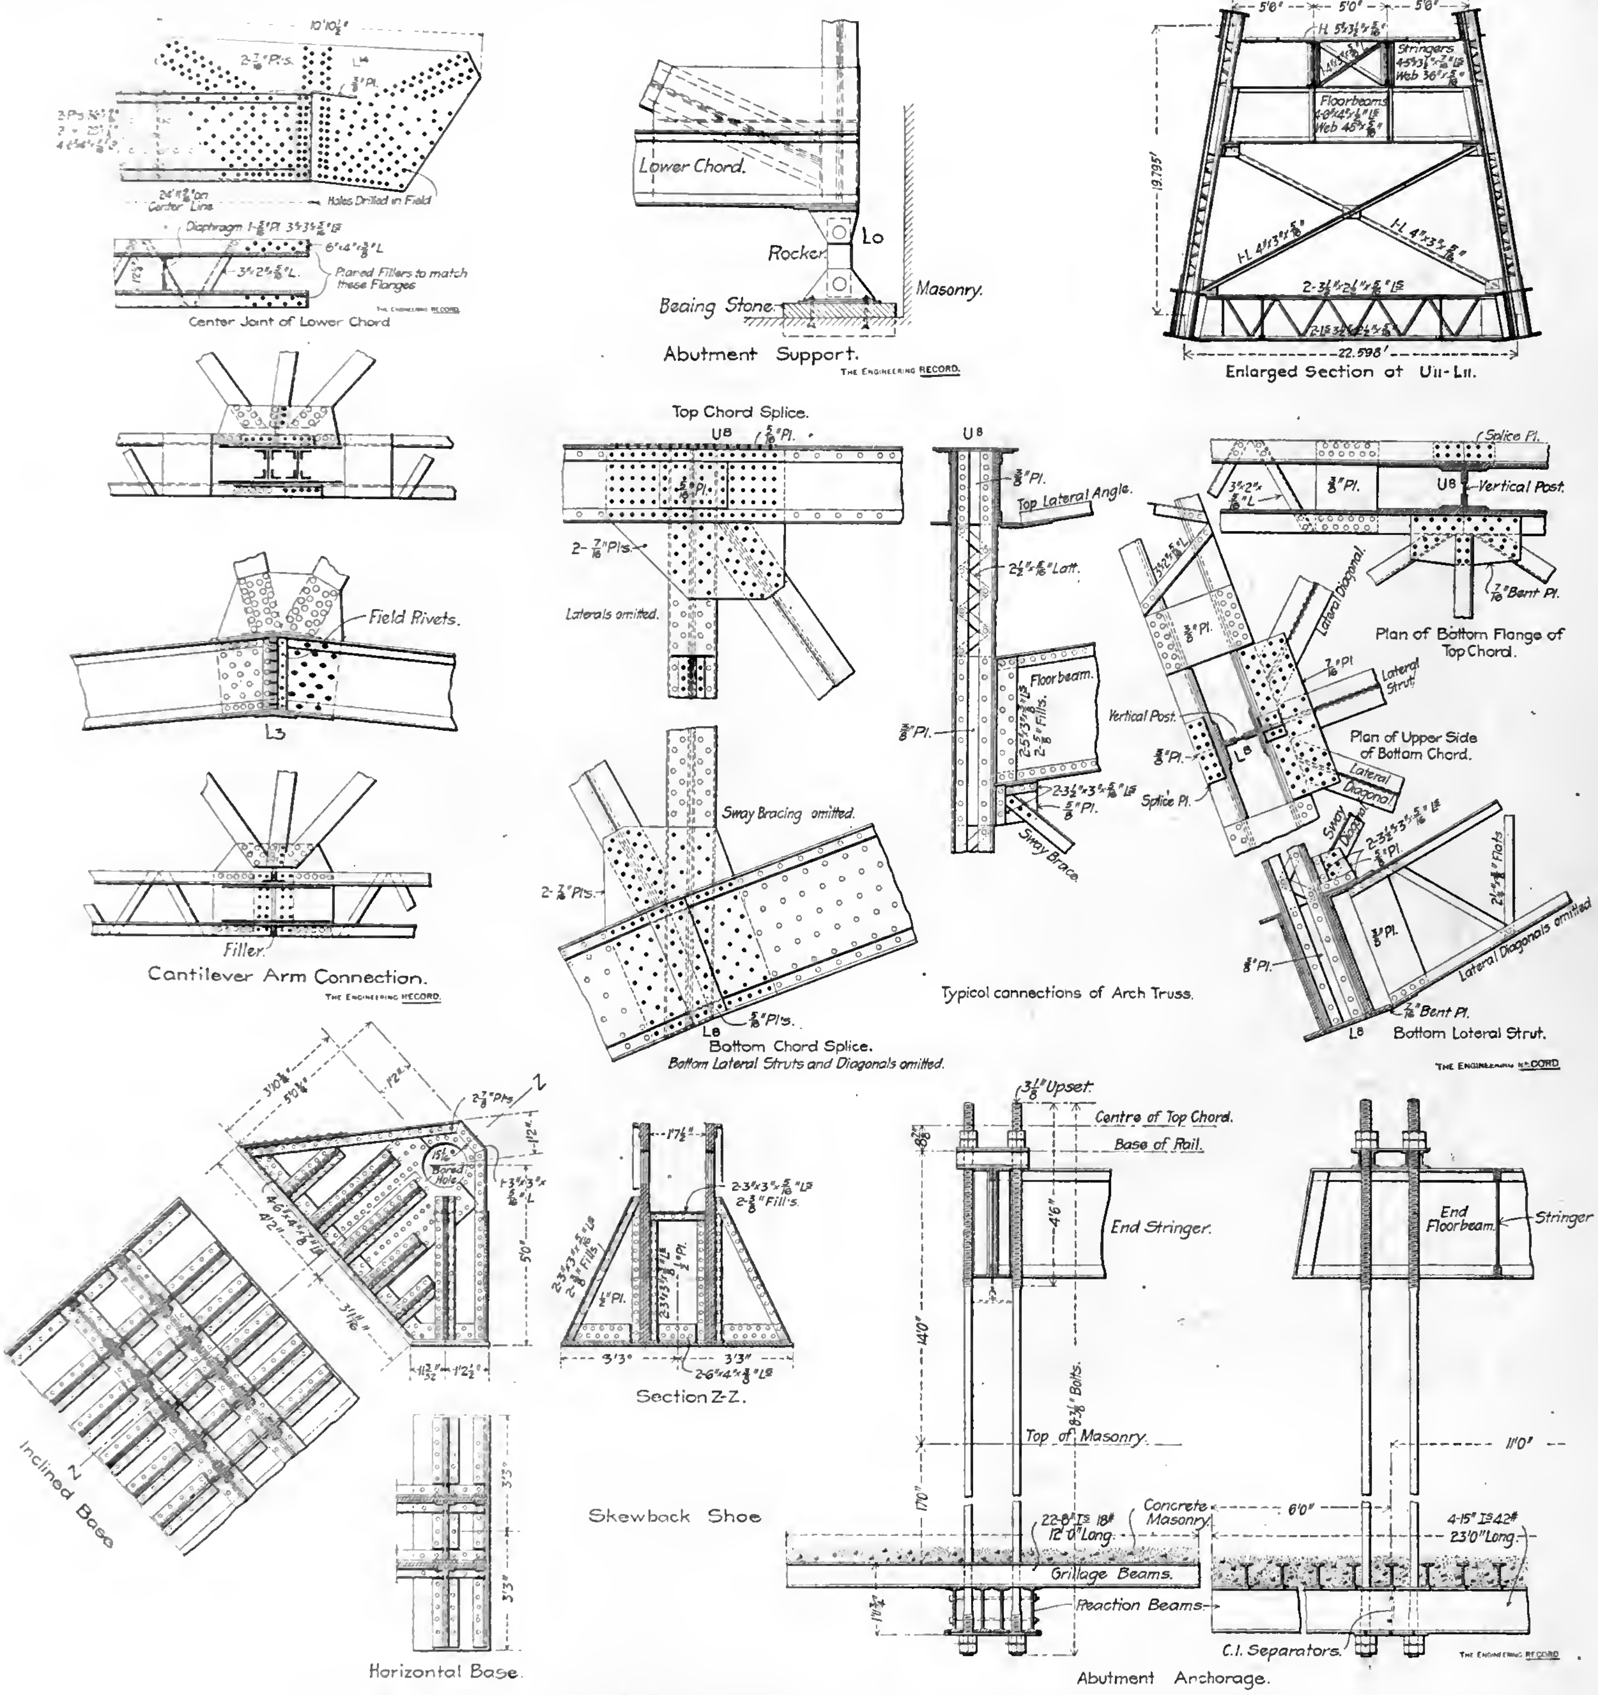
The design of this bridge differs in some respects from that usually adopted for arches of this type. The most radical difference was in the character and shape of the skewback shoes and their masonry seats. They are made entirely of riveted steel instead of being cast as usual, and have the pin bearings thoroughly braced by solid transverse diaphragms which also serve to distribute the load over a widely extended base plate. The shoes were set in the planes of the trusses and symmetrical with them, instead of being set as usual in vertical planes, thus permitting the 15-inch pins to be at right angles to the planes of the trusses. The base plates were made in two planes, one normal to the pressure from the completed arch, and the other horizontal to receive vertical erection stress and to improve the stability of the shoe on the masonry which was built with a beveled seat to correspond with the inclined base.

The total weight of the superstructure was 932½ tons, and although it was built in the shops in one month the work was so accurately done and carefully inspected that no errors whatever were discovered in the field and it was assembled there without difficulty. This accuracy was secured by the use of special standards of measurement for the shops and for the field work, and by the greatest care in laying out the masonry and locating the shoes and truss centers. The principal points were determined by many repetitions of transit and level lines which were conducted on both sides of the canon, and tied together by triangulation but which could not have the main span directly measured until after its erection was nearly complete.



THE SKEWBACK SHOES BEFORE SHIPMENT.

At the bridge site the almost vertical banks of the canon are of weathered shale which was excavated to sound rock for the foundations of the skewback piers and abutments. On one side the slope between the pier and the abutment was steeper than that of the lower chord of the shore span and chases were cut in the surface wide enough to receive the lower part of the trusses and give clearance for inspection, painting and free drainage of surface water past the piers to the canon. The main piers were made out of cut stone masonry on concrete footings, but the abutments were made entirely of concrete enclosing, near the base, grillages of I-beams for anchorage platforms. These were about 8 feet below the tops of the reaction rods which had screw bearings on top of the end floorbeams and were proportioned for a maximum tension of 280,000 pounds per truss, erection stress. In order to diminish this stress and reduce the great friction on the adjustment nuts when the center panel was connected the shore arms were heavily counterweighted and, the projecting ends of the semi-trusses being kept high during erection, were easily lowered to position at the center panel by slacking off the eight nuts on each end floorbeam.



DETAILS OF THE RIO GRANDE BRIDGE OF THE PACIFIC RAILWAY OF COSTA RICA.

Two steel tapes were purchased in the United States, sent to Washington and standardized by the United States Government, corrected for every ten degrees of variation in temperature, and were furnished with spring tension arrangements so that exact measurements could be made under the same tension. One of these tapes was sent to Costa Rica to be used as the standard in laying out the work, the other was retained in the United States and was used in the shops as a standard.

The work of erection in the field was carried on under great difficulty. All of the steel for one-half of the bridge had to be transported across the valley by cableway. The crudest kind of false work was used to save the expense of sending down lumber for the erection of the shore spans.

In order to allow a certain amount of leeway, to make up for any possible small errors in the placing of the shoes, the center panel members were made somewhat shorter than the calculated length, the holes in one side of the center gussets and splice plates left blank, to be drilled in the field after all parts had come to a full bearing, and a number of planed shimming plates were shipped to be used as needed.

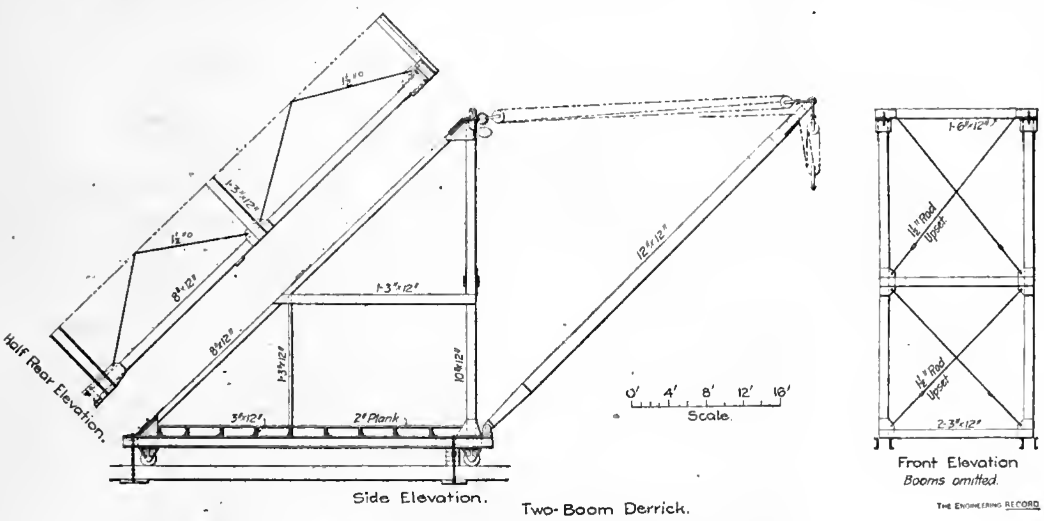
As a further safeguard, the center chord sections were held at the shop until the arms came sufficiently close together to allow of direct exact measurements, and thus correct any errors in that shop before shipment. It was, however, found that no corrections of any kind were necessary, and the works were telegraphed to ship the center sections exactly as designed, thus demonstrating the great accuracy obtained in the shop and in the field in the execution of this work.

During erection, the shore arms were bolted up solid to form continuous trusses so that the center arch could be erected from each abutment with only vertical anchorages, the top chords being designed to carry the entire tension from erection loads. After erection, the splice plates were removed from the bottom chord panels at the ends of the supported spans. The top panels were left solidly riveted up, as it is not thought serious to allow a slight bending in the comparatively shallow chord under partial loading, and a much more rigid structure is obtained by not interrupting the top lateral system at this point.

The Pacific Railway of Costa Rica are very proud of the successful completion without a hitch, of this important piece of engineering work, and are now regularly using the bridge to carry their traffic.

Theoretically the superstructure consists of a pair of spandrel braced arch trusses continued beyond the skewback piers to form cantilever arms 47¼ feet long which support the river ends of the two approach spans and reduce their lengths from 118 feet 1½ inches to 70 feet 10½ inches. For the practical reasons already stated the top chord is a continuous riveted member 684 feet 11¼ inches long between centers of abutment pins, and is designed to resist maximum tension and compression stresses. The cantilever arms are two panels long, and at their ends the bottom chords are spliced to those of the shore spans with bolts in slotted holes for longitudinal expansion. Except for a camber of 3 inches in the center the top chord is horizontal and the bottom chord changes inclination at every panel point, conforming to the chords of segments of a parabolic arc of 55.924 feet rise and 448 feet 8¼ inches chord. The lower chord, from the skewback to the abutment, corresponds to the chords of segments of one-half a parabola with a rise of 58.14 feet and a chord of 236 feet 3 inches.

The arch trusses are battered 1:6 and are 40 feet apart on centers of shoes and 16 feet apart on centers of top chords. They have, as shown in the strain sheet diagram, vertical posts and single panel tension diagonals arranged like the web members of a Pratt truss, and having the same arrangement continued through the cantilever arms and shore spans so as to prevent a similar though unsymmetrical appearance, and resemble semi-arch trusses balancing the main arch thrusts. The track is carried on two lines of stringers just below the top chord level, and the trusses are braced together with top and bottom laterals and bracing in the vertical transverse planes through all panel points.



Traveler for Erecting Arch and Shore Spans.

The top lateral system consists of single 5x3½-inch angle horizontal transverse struts and X-brace angles field-riveted to connection plates on the lower inside flanges of the top chords and to the top flanges of the stringers. The bottom lateral system consists of horizontal transverse struts and X-braces in the planes of the bottom chord. All of these members are I-shaped struts made of two pairs of angles latticed, and are of equal depth with the bottom chord of the arch truss and field riveted to it with bent connection plates across the top and bottom flanges. Between the bottom transverse struts and the floorbeams there are in each panel, from one to three panels of X-bracing of single angles which are all 4x3x5/16-inch except at the skewback piers where they are 6x4-inch. Where there are two or more panels of X-bracing there are intermediate horizontal struts 18 inches deep with rectangular cross sections made with four 4x3x5/16 angles, latticed. Panel U6 L6 is like U5 L5, panels U4 L4 and U8 L8 are like U7 L7 and panels U2 L2, U3 L3, U10 L10, U11 L11, U12 L12, and U13 L13 are like U9 L9.

The top chord is made in single panel sections with milled ends abutting on the center lines of the vertical posts and spliced with top and bottom flange cover plates, outside web plates and inside gusset plates which receive the vertical and diagonal posts as shown in the detail at U6. All splices were assembled, fitted and reamed in the shops, all splice plates were shipped loose and all their rivets were driven in the field. The bottom chords are also made in single panel lengths, similarly spliced, but they have no cover plates. The webs are connected by vertical transverse diaphragm plates near each end and the flanges are latticed by zig-zag 3x2½-inch angles.

At the center joint only, there are vertical angles riveted to the ends of the webs of both sections and these were connected by rivets through their outstanding flanges after the two chord pieces were assembled. Here, too, half the holes in the gusset plates were drilled in the field by pneumatic tools so as to be certain to match the corresponding holes in the chord pieces which were drilled in the shops. At bottom chord panel points L3 the gusset and splice plates were all field-riveted to the chord section nearest the skewback, and bolted, through slotted holes, to the other chord section so as to allow longitudinal and prevent transverse motion as shown in the detail drawing.

At the abutments shoes are riveted to the under sides of the lower chords and receive the upper pins of short vertical rocker posts which have lower pins in ordinary pedestals bolted to the masonry as shown in the detail elevation at L0. The floorbeams are made with 45x5/16-inch web plates and 6x4x½-inch flange angles and are divided into three nearly equal panels by two pairs of 3x3-inch vertical web stiffener angles. The ends of the floorbeams are beveled to correspond with the batter of the trusses and are riveted to the faces of the vertical posts with 40 rivets in four vertical rows at each connection. The stringers have 36x7/16-inch webs and 5x3½x7/16-inch flange angles and are seated on the top flanges of the intermediate floorbeams to which they are riveted with two rivets at each end. They are web connected to the end floorbeams which are set correspondingly higher. The top lateral diagonal angles were cut to clear the bottom flanges of the stringers, and were riveted to them with short connection plates. Between the stringers one of the middle sections of the diagonals in each panel is continuous and the intersecting one is cut to clear it and spliced by a flat plate riveted to the bottom flanges of both angles.

All the web members of the arch truss have I-shaped cross sections made with four flange angles, which, except for U0 L0 and U13 L14 have latticed webs. These two members have solid plate webs and solid cover plates riveted to the flanges. The longest members are made in two or three sections each, spliced with web and flange cover plates, the latter being extended for connection with the horizontal longitudinal struts. The rocker posts at the abutments are 18⅞ inches long on centers, with rectangular closed cross section made with two 8-inch channels and two 11-inch cover plates. Both pins are horizontal, and the upper one engages a shoe with vertical web plates of unequal heights, riveted to a top plate which is set obliquely to engage the inclined surface of the bottom chord of the battered truss.

Material for the superstructure was shipped from New York direct to Port Limon, in three invoices, two by regular line boats and one by a chartered steamer. It was thence shipped by rail to the site and unloaded by steam derricks in a storage yard on the east side of the canon. A cableway with a main cable about 2½ inches in diameter and 900 feet long was erected across the canon and by it all the material for the west half of the bridge; which was painted red, to distinguish it from that for the eastern half which was painted white; was transferred to the opposite side in readiness for simultaneous erection. The 8-ton skewback shoes on the main piers were first set on mats ⅝-inch thick which were made of layers of felt soaked in hot coal tar. These covered the whole top of the masonry and were used to bed the base plates instead of grouting them, because of the difficulty of injecting the grout thoroughly under so large a base plate without vent holes for the escape of the air.

Between the piers and the abutments the trusses were erected in their required position on timber blocking by the use of the two overhead traveling derricks which were designed for the cantilever erection of the arch trusses. The joints at L3 were bolted tight and all other joints were riveted permanently and the arch trusses were built out panel by panel until their increasing moment produced a slight uplift at the abutments. All blocking was then removed from under the shore trusses and the nuts on top of the vertical anchor bars were screwed down until the points Uo were depressed about four inches below their final positions. The erection was continued to the center panel and the last sections of top chords were inserted several inches above their final positions. The shore ends of the trusses were then loaded with several hundred tons of ballast so as to partly balance the moment of the overhanging arms and reduce the tension on the anchorage arms and the nuts of the latter were slacked off, allowing the top chords to assume their required positions when the last joints took the calculated compression and the blank web splice plates were drilled and riveted and the rivets were driven in the rest of the top chords and in the floor system where the holes had before been filled with bolts exclusively. The other field rivets, including those in the bottom-chord splices, were driven as soon as possible after the joints were assembled and nearly all of them were driven by pneumatic hammers operated from steel pipes run to a Chicago Pneumatic Tool Company's compressor, which was driven by steam from a locomotive boiler.

The erection travelers were duplicates, shipped with the steel trusses from New York, each consisting essentially of a horizontal platform about 18 feet wide and 40 feet long which carried two stiff-leg derricks, one on each front corner. The 34-foot masts, the 50-foot booms, the stiff legs and their horizontal braces were of timber. The diagonals, longitudinal sills and all connection plates were of steel. The traveler wheels had a tread 15 inches wide between the two flanges, and had a diameter of 18 inches. They rolled on the horizontal flanges of a pair of 3x3-inch angles covering the upper corners of 12x12-inch longitudinal timbers which were beveled to fit the top chords of the arch trusses and give horizontal upper surfaces. These timbers were countersunk bolted on top of short cross ties which projected beyond the edges of the longitudinals and were countersunk to clear the rivets in the top chords to which they were clamped with steel yokes and set screws engaging the ends of upper flange angles. Each boom had a normal capacity of 17,000 pounds, and the heaviest pieces lifted weighed about 18,000 pounds.

The construction of the travelers was somewhat modified from the design shown in the accompanying elevations, by the addition of a horizontal strut about 40 feet long and 5 feet below the tops of the masts, beyond which it projected equally on both sides. The extremities of these struts were braced to the tops of the masts and to the working platform, by inclined struts. This gave additional transverse stiffness to the traveler and afforded a connection for whip lines and light tackles outside the top chords for convenience in handling members in the inclined planes of the trusses. The transverse floorbeams of the working platform were 12 feet beyond the sills on each side and were permanently braced. The working platform was elevated about 6 feet above the tops of the wheels and its transverse floorbeams projected about 12 feet each side of the traveler sills and were kneebraced to them, inside and outside, thus affording clearance under the floor for small cars on the permanent bridge track to deliver material through the traveler, under the floor to the derrick booms.

When in service the traveler was anchored to the top chords by chains around the sills and the top chords, which were tightened by pairs of wedges, and the front wheels were blocked up clear of the rails. Temporary kneebraces were also set between the ends of the floorbeams and the top chords, and the tops of the masts were guyed to the top chords several panels back, by wire ropes with adjusting tackles. The derrick booms were rigged with manilla rope tackles operated by one six spool Lidgerwood hoisting engine on each traveler. The total weight of one traveler, engine and rigging was about 22 tons. The bridge was erected by fifty men in about three months, and although only a dozen of the men were experienced bridge erectors sent out by the contractors, no casualties were reported.

(To be continued.)

Sewage Disposal at West Bromwich, England.

About three years ago the town council of West Bromwich, Eng., acting on the suggestion of the borough engineer, Mr. A. D. Greatorex, caused three large bacteria or contact beds to be constructed, in order to determine whether the sewage of the locality could be successfully treated by that method at all times of the year, and further, to determine whether by means of a double contact an effluent could be obtained of sufficient purity to render unnecessary any further purification. The results of this investigation are embodied in a report by Mr. Greatorex to the town council some time ago, from which the following notes have been condensed:

For the low-level sewage, double contact is used, the beds being 120x60 feet in size. The average depth of filtering material in the coarse-grained bed is 3 feet, consisting of screened engine ashes from ½ to 2 inches in size. In the fine-grained bed the material is 3 feet deep and from ¼ to ½ inch in size. The sewage reaches the coarse-grained bed by means of three 15-inch gates. The iron troughs for distributing the sewage are 15 inches wide and laid on the surface of the filtering medium. The beds are not underdrained but have six 4-inch sluice valves on either side connected to 6 and 9-inch cast-iron pipes, which discharge into manholes at the lower end of the beds. This system of emptying the beds has been found to be satisfactory. The coarse-grained bed discharges into the fine-grained bed, and the latter discharges into a 12-inch earthenware pipe connected to a pump well near the engine house, from which it is pumped to the land filtration area.

The single coarse-grained bed for the high level sewage is 60x42 feet in size, with an average depth of material of 3 feet. The sewage passes first through the detritus tanks, then through two 15-inch valves onto the bed, being distributed by means of two 15-inch cast iron troughs. The outlets for the filtrate are six 4-inch valves connected to cast iron pipes leading to two manholes from which the liquid flows through a 9-inch earthenware pipe to the land filtration area. The latter takes the place of the fine bed used for the low level sewage.

The method of working the beds is as follows: The sewage is allowed to flow into the coarse-grained bed until the level has nearly reached that of the bed material. The inlet valves are then closed, and the bed allowed to stand full for about two hours. The same period of resting full is given for the fine-grained bed. After being used the beds are allowed to stand empty for three hours, and are used three times every 24 hours.

The analyses made showed that the average amount of suspended matter contained in the sewage was 77.39 parts per 100,000, which was reduced in the coarse-grained beds to 9.34, and in the fine-grained bed to 0.95 parts per 100,000. The effluent from the land contained traces only. The reduction of the oxidizable matters in solution was from 3.251 to 1.512 parts per 100,000 and then to 0.457, thus showing an average reduction of 53.4 per. cent. by the coarse-grained bed and a total reduction of 85.9 per cent. by the combined beds. The total purification after land treatment was 88.9 per cent. The reduction of the nitrogenous organic matters, as indicated by the albuminoid ammonia was 47 per cent. by the coarse-grained bed, 78.6 per cent. by the combined system, and 82.4 after land treatment. The accompanying table shows in parts per 100,000 the results of the treatment on both the high and low levels.

	High. level, land.	Low level. Fine. bed.	Land.
Oxygen consumed	0.369	0.457	0.360
Albuminoid ammonia	0.042	0.068	0.056
Total suspended matter....	0.660	0.950	None.
Nitric nitrogen	1.260	0.447	1.239

The capacity of the beds has been found to remain practically constant after they have been in operation for a period of about three months, and in round numbers is said to be about one-third of the tank capacity. It is stated that the final effluent is clear, entirely without odor, remains perfectly sweet on keeping, and is fit to discharge into the river, however small the relative volume. Since the beds became regular in their action, neither the effluent nor the beds have become foul. Analyses taken later than those given here have shown that the effectiveness of the treatment has in no way diminished.

The conclusions drawn from these experiments were: (1) That the sewage of West Bromwich can be successfully purified by the bacterial process; (2) that this process is efficacious at all seasons of the year; (3) that the final effluent from the fine-grained bed on the low level is sufficiently pure to discharge into the stream without further purification; and (4) that detritus tanks should be provided on both levels to remove as much mineral and suspended matter as possible. These investigations led to the recommendation of a system of contact beds of sufficient capacity to deal with the entire flow of sewage.

The average daily dry weather flow from the low level system is stated to be 800,000 imperial gallons, and from the high level, 400,000 gallons, making a total of 1,200,000 imperial gallons to be treated. The low level sewage is comparatively weak, although it contains a certain amount of manufacturing wastes. The corporation does not allow acid or wash water from galvanizing works to discharge into the sewers. The high level sewage is also dilute, though of rather a stronger character than the low level. It is free from admixture with manufacturers' waste, except that from breweries.

The scheme finally adopted for the treatment of the whole of this sewage and which is now being carried out, was described by Mr. Greatorex at a recent meeting of the Association of Municipal and County Engineers held at West Bromwich, substantially as follows:

Low Level.—Three detritus or open septic tanks, each 160x30 feet in size, with an average depth of 5 feet 6 inches will be provided, giving a total capacity of about 500,000 imperial gallons. Eight coarse-grained and eight fine-grained contact beds, each 120x60 feet, will give with the existing ones a total area of 14,400 square yards, capable of treating 1,600,000 imperial gallons per 24 hours on an 8-hour cycle. The effluent from the fine-grained beds is to be collected and passed over an ærating bed having an area of about 1,000 square yards. All storm water up to four times the dry weather flow will be treated on land areas which have been underdrained and have a collective area of about 34 acres. This will allow for the treatment of about 3,000,000 imperial gallons of storm water per day.

High Level.—The existing detritus or open septic tanks will be extended so as to have a capacity of about 240,000 imperial gallons. Nine coarse-grained bacteria contact beds, each 100x60 feet, will be constructed, capable of dealing with about 1,444,000 imperial gallons of sewage per 24 hours on the 8-hour cycle. The effluent from the coarse-grained beds will be conveyed by means of a 12-inch earthenware pipe to some of the land areas, which have been underdrained, and treated there instead of by fine beds. This land has a collective area of about 28 acres. From this it will pass directly into the brook. In order to deal with the storm water, part of one of the areas will be filled with material to form a special storm filter capable of dealing with 2,000,000 imperial gallons per 24 hour.

As regards the storm water, storm overflows are being provided both on the low and high levels for the purpose of regulating the flow. One overflow is arranged so as to come into operation when the sewage is diluted with more than five times its volume of storm water (i. e., when the sewage is flowing at a rate exceeding six times the dry weather flow) and another is arranged so that the sewage and storm water up to twice the dry weather flow will pass to the contact beds and thence onto the land, and the balance between twice and six times the dry weather flow to the areas to be reserved for the treatment of excess storm water.

The detritus tanks are constructed with blue brick walls in cement on concrete foundations and are provided with scum boards and cast iron inlets. The bacteria or contact beds are constructed in Portland cement concrete, 6 inches thick, with cast iron outlet valves at regular intervals instead of underdrains. Blast furnace slag will be used for filling, ½ to 2 inches in size for the coarse beds and 1/16 to ½ inch for the fine beds. The cost per square yard of the coarse beds on the low and high levels complete, including filling, is about $3.35 and $3.60 respectively, and the cost of the fine beds about $3.60 per square yard.

The East Boston Tunnel, under Boston Harbor, and the Washington Street subway have been leased for a term of twenty-five years to the Boston Elevated Railway Company by the city. The rental is fixed by the contract at 4½ per cent. of the cost of construction.

An Illuminated Tracing Table in the drafting rooms of the Metropolitan Water-Works, Boston, is used for making tracings on thick paper or of drawings having weak lines. An ordinary large drafting table with a thick white pine top, having a large drawer sliding across the whole width of the table was adapted for this special purpose. A rectangular hole was cut in the middle of the top of the table and a large piece of ¼-inch French plate glass set in it so as to be flush with the surface of the table. The drawer was painted white on the inside and in it was set a 6-light cluster of incandescent lamps mounted on a base block. The lights have a white porcelain reflector beneath them and are fitted with independent keys. Lamps of any usual candle-power may be put into the sockets, but 8-candle-power lamps have been found sufficiently strong for most purposes and stronger ones are very trying to the eyes. Flexible leads are taken from a large wall switch to the cluster of lights so that the whole cluster may be lighted or shut off at one operation, but by means of the independent keys one or more lamps may be cut out separately. A number of vent holes were bored in the sides of the drawer to prevent overheating. The illumination is not quite uniform over the whole area of the glass, but by sliding the drawer or moving the block carrying the lamps in the drawer the most brilliant illumination can be obtained under that part of the work where it is most needed. A great variety of uses have been found for the table, such as comparison of alternative studies for a structure, comparison of contours of proposed surfaces with original contours, and the tracing of additions directly on to brown paper drawings and prints.

Electric Lighting in the Union Trust Company's Building, Providence, R. I.

The City Realty Corporation of Providence has recently completed a 12-story building on Westminster, Dorrance and Middle Streets of that city, with accommodations for the Union Trust Company's banking offices on the ground floor and for general offices on the other floors. The electric light wiring is of particular interest in that the three-wire system there installed makes use of its metallic conduits to replace the neutral wire. Besides saving some 40,000 feet of wire, it is claimed that this system makes it practically impossible for fire to start from an electrical source, since if a defect should develop in the insulation, allowing a leakage of current, there would be a dead short circuit, blowing the fuse at once, instead of causing arcing with its attendant dangers of heating. Like all modern buildings, it is so arranged that wires can be inserted or withdrawn from the conduits without disturbing the floors or partitions; as a matter of fact the building was completed before a single wire was drawn into place. Another commendable feature of the installation is the provision of an emergency tie circuit, on most of the floors, to be put in commission during temporary disablement of any of the regular circuits.

The conduits are of iron pipe varying in size from ½-inch to 3 inches in diameter; ½-inch pipe being used for all tap circuits. The threads on the pipe joints were cut dry and the specifications required that particular care should be taken to exclude any particles of insulating material from the joints in making them up. As a further precaution, all joints were bonded with a copper wire across the coupling. To ensure a zero potential in the conduits at all times, they are grounded to the steel frame of the building. This is expected to prevent electrolysis of the plumbing system or any other metal work in the building. Wherever a wire connection continues as the neutral line, contact is made to the pipe by inserting a brass bushing fitted with a flexible bare copper wire.

The best conception of the system as a whole is obtained from the accompanying elevation diagram. As will be seen, the three mains are brought into the building through a subway from the street mains of the Narragansett Electric Lighting Company. The neutral wire goes directly to the neutral bus bar of the main switch-board in the basement but the positive and negative leads first pass through fused knife switches before going to their respective bus bars. From the main board a riser is taken to a panel board on each floor. The lower ends of these riser conduits are tied together by a neutral iron bar. The panel boards are of Italian marble and are enclosed in cabinets with glass doors. A photograph of one is shown herewith with the door open. The board is set in an angle-iron frame which swings on hinges, giving ready access to the back.

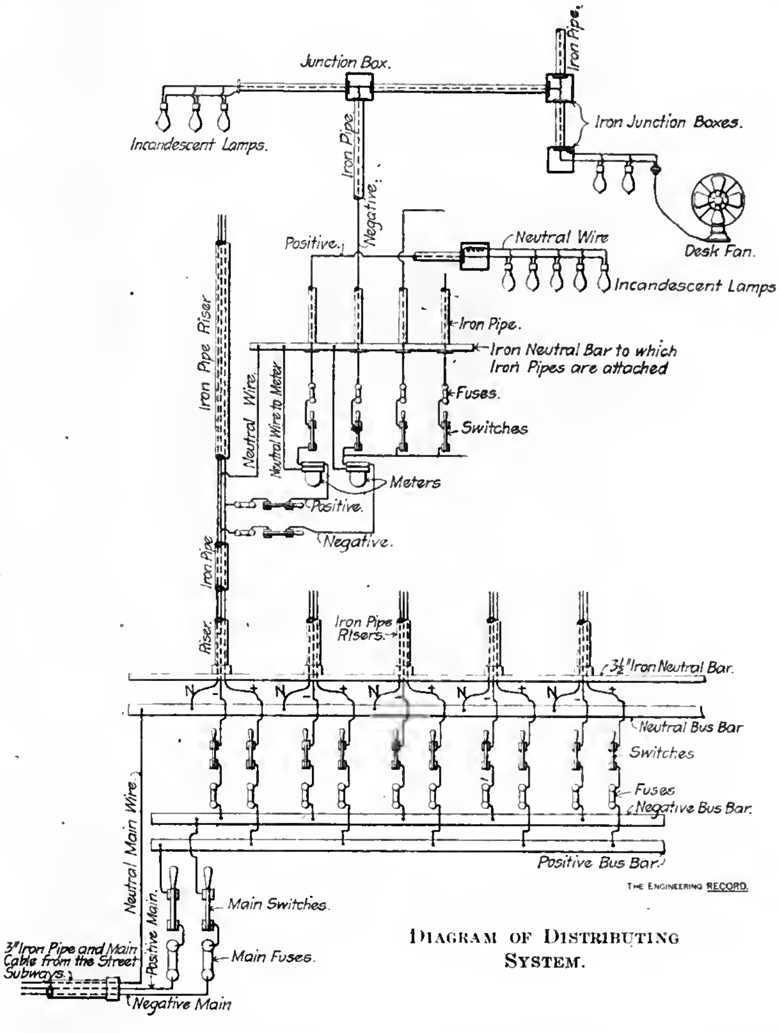


Diagram of Distributing System.

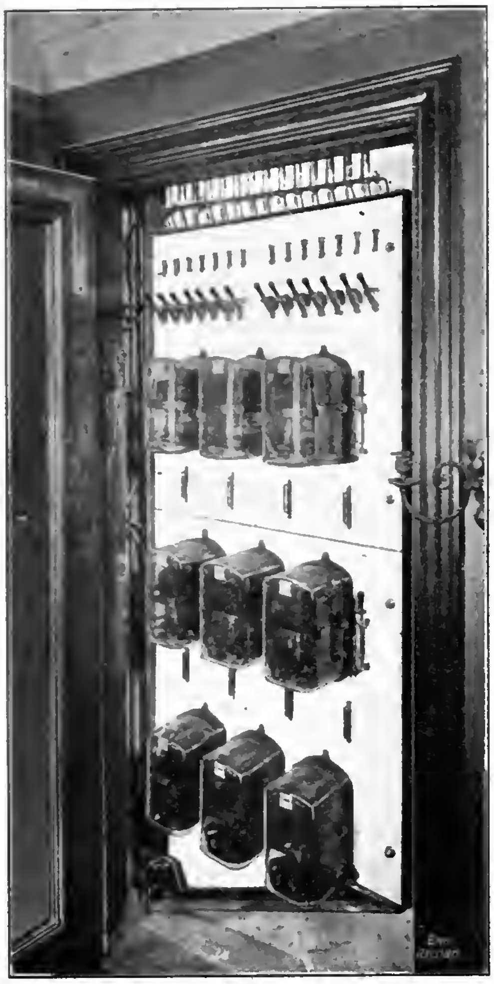
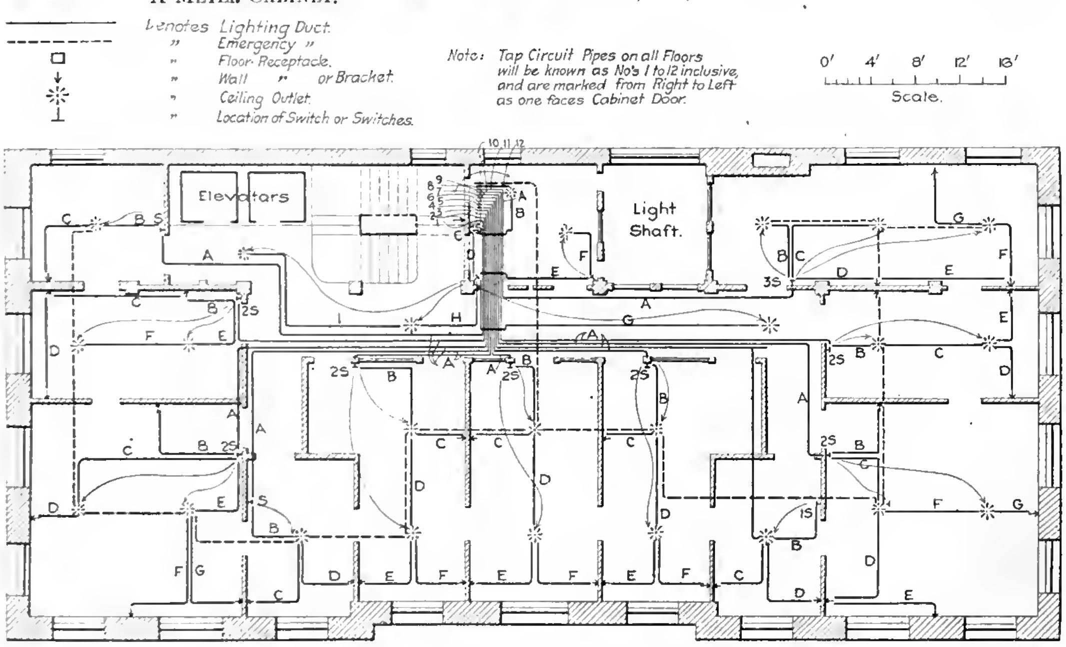
At the distributing panels the circuit is subdivided into a number of branch circuits, as a rule one for each room. This prevents the entire floor from being darkened in case of local trouble in any room and gives an opportunity for measuring through watt-meters the current used by the individual tenants. The board shown has nine General Electric Company's meters with glass cases. This number will allow one for each of the greatest number of concerns likely to occupy one floor, that is nine tenants. The meters can be connected on the back of the board into one or more circuits as may be desired. The switches at the top of the board control the various circuits for that floor. Directly above these are D. & W. enclosed fuses which protect each branch circuit. Between the rows of meters are fuses for the protection of mains for that floor and above the top of the board can be seen the ends of the conduits containing the positive and negative leads, as the case may be. Beyond the panel board the circuits are of the simple two-wire system, the conduit serving as one leg. The method of connecting the ends of the conduit by a neutral bar is also shown in the photograph and at the extreme right the attachment of the neutral wire. The positive and negative wires have long flexible ends to allow the board to be swung outward. It will be noticed that the conduits are not used for the neutral conductors except on the floor branches.



A Meter Cabinet.



Fourth and Seventh Floor Wiring.

The wiring of the various floors differs somewhat in its details but the plan here shown for the fourth and seventh floors may be taken as typical. It shows 12 regular circuits and one emergency circuit. In this particular the second to ninth floors inclusive are alike. The first floor has one more regular circuit and the tenth, one less. The basement, ground floor, eleventh floor and loft have no emergency circuits, but the eleventh has an emergency wire between all of its fixtures, so that any part of it may be connected in at will to supply a fixture from an adjoining circuit until its own can be repaired. The basement and loft have five circuits each, the eleventh floor 12 and the ground floor 13. On the plan the full lines represent regular circuits and the dotted lines the emergency circuits. In this connection it must be remembered that the lines show conduits only and that the number of conductors they contain varies. Some idea of the number of wires in any conduit may be obtained by tracing out the switches connected to that line. There is always one switch for each ceiling fixture. These switches are placed on the side walls, and where there are more than one to a circuit they are placed side by side. All side lights are controlled by the buttons on the sockets.

In general all bracket outlets and receptacles are 6 feet above the floor and all switch outlets 4 feet above. All piping, except that supplying the side wall lights in the banking room, is run on the floor above the rooms in which outlets connected to that pipe are installed. All pipes are laid at right angles to, or parallel with, the side of the building. The approximate location of the ceiling boxes is 1½ inches below the bottom of floor beams. These boxes are set flush with the completed ceiling. The space from center to back of top plate on switch boxes is filled in with expanded metal lathing leaving ⅝-inch for finish lathing and plaster.

The telephone wires connecting all of the rooms are run in 1½-inch conduit with outlets in the baseboards and risers in the halls. These are made large enough to provide for the greatest number of wires that may ever be needed.

The building contains 75,000 feet of metallic conduit, 120,000 feet of Okonite rubber insulated wire, 600 switches and 1,300 lamps. The banking rooms of the Union Trust Company alone have nearly a mile of pipe for electric wires. The system was designed by Mr. William Carpenter Woodward, of Providence, and the work was supervised by Mr. H. C. Wright. The telephone system was furnished by the Couch & Seeley Company, of Boston, and the fixtures by Messrs. Mackinney & Waterbury of the same city. The C. S. Bush Company was the contractor for the wiring.

Separate Versus General Contracts.

A paper by G. E. Gifford in the Proceedings of the American Society of Civil Engineers for August, 1902, p. 533.

The topic under discussion will be regarded by the speaker primarily from the standpoint of the contractor, and by giving the views of the contractor, he hopes to show the owner, the purchaser, or the consulting engineer, that his own interests lie with the contractor in this matter. He believes that contractors almost universally will agree that the dividing up of contract work, so that each principal branch is under original contract with the purchaser, is preferable to the making of one general contract which must be sublet to specialists in the different trades.

The speaker has talked with many contractors on this subject, and does not recollect ever hearing one say that he preferred the general contract system. It is recognized, of course, that there have been formed large contracting firms and corporations who are ready to undertake work of almost any magnitude, and involving many different trades. This has been brought about not so much from preference as from necessity, because the greater part of government and municipal work is being let in this way, and, in order to bid upon it at all, the contractor must take it as a whole. This is also true of some private work, especially the large building constructions.

In many cases the contracting firm consists simply of an office; practically all its actual operations are performed by sub-contractors, and the most important man in the whole outfit is the purchasing agent. He does what the consulting engineer or the architect should do at first hand for his clients. In other cases the contracting firm makes a specialty of some particular branch of work, we will say masonwork or steel-work, and actually carries out this portion of the contract with his own appliances or at his own shops. The remainder, which he cannot do himself, he is obliged to sublet or "farm out," as it is called, or else undertake operations with which he is not familiar and which he can only carry out at a disadvantage. He would much prefer to have only such work as he himself can perform, but is obliged to take the remainder in order to get his portion. The consequence is he is loaded up with a lot of work which he is not adapted to perform, but for which he has to be financially responsible, and he either does it at a loss to himself or at a loss to the purchaser.

It may be urged that the proper way to overcome this difficulty is by a combination of contractors in different lines who are willing to unite their bids in a grand total, including only one profit, and each one then perform his portion of the work. This is no doubt what the purchaser, the engineer, or the architect thinks will be done when he receives proposals in this way. The only trouble with this theory is that it does not harmonize with practice. There is not an entire unanimity of opinion and complete trust in one another among contractors in different trades, which is no doubt to be regretted, but which fact, nevertheless, remains. In a community-of-interest contract someone has to be the principal; someone must be designated as the main contractor, must receive the instructions, confer with the owner or his agents, draw the pay and settle with the others. There is the rub.

What is the practical way in which general contract work is actually taken?

We will assume our contract to be a large city bridge, involving substructure, possibly with pneumatic foundations, dredging, cutstone masonry, concrete, excavation, embankment, paving, sidewalks, perhaps some sewers to be extended or moved, and water pipes to be changed. Then we have the superstructure with a draw span which will involve not only the structural steel, but various kinds of machinery, electric motors, electric lighting plant, a little carpenter work, some automatic gates, fancy hand railing, asphalt paving, and painting. There have been bridges let in New York City the bidding sheet of which showed more than one hundred items for which prices had to be inserted.

We will assume further that the substructure and the superstructure (it being unnecessary to designate specifically before this Society just what items are included under the above heads) are approximately equal. The bridge builder, for example, begins to prepare his bid and finds that he must either combine with some other contractor who will take care of all parts of the work which are technically known as substructure or general contract work; or he must get prices on the separate items from tradesmen of all branches; or he may assume that he knows enough about work of this kind to make his own figures for everything.

The chances are that the first mentioned alternative will be met with the statement: "We will make you figures for our part of the work provided you will agree to tie up with us." This may be the most satisfactory way in the end, provided the bid is successful; if not, there follow the usual charges, expressed or implied, that the bidder was "thrown down" by a bid too high, and if he is the successful bidder and finds that other figures, better than those given to him, have been submitted, he regrets his inability to deal with a cheaper party.

This plan also presupposes absolute confidence between the parties to the proposal, as to fair dealing all around, and this does not always follow. Many of the largest contractors and steel workers absolutely refuse to make prices to other contractors in advance of the receipt of the contract; and in some cases will even decline to bid to another contractor, even though he holds the contract; the position of sub-contractor being so undesirable, for many reasons, particularly the inability to deal directly with the owner, and the financial delays and losses involved in case the main contractor is slow pay or becomes financially embarrassed. The speaker knows what he is saying, in making these statements, from the fact that the firm which he represents almost invariably declines to assume the position of sub-contractor on any work. He knows of others who feel the same way.

Returning to the second method of preparing a proposal, that of getting separate prices on all the different classes of work, we find a marked disinclination, on the part of dealers and tradesmen, to give their best figures for bidding purposes, if they will give them at all. An inquiry of the sort is likely to be met with the question: "Have you this contract?" The answer being "No," it is likely that an excuse will be offered, such as "too busy to figure just now," or else the statement: "We will give you a safe price with which to bid; but, in case you secure the contract, we may be able to do better, and expect to hear from you again." Is this likely to be satisfactory to the bidder desiring to make a close bid? And after he had added his 5 per cent., 10 per cent., or whatever he sees fit to cover the financing of the job, contingencies, and his profit, is it likely to be an economical method for the purchaser?

No doubt, if every contractor had the skill and knowledge of costs and conditions to make up his own figures for all classes of work, it might be best to make a general contract. Sometimes he attempts to do this, with the result that he is entirely too liberal in his estimate, and loses the work, or else makes a mistake somewhere, and, when he comes to do the work or purchase his supplies, finds that there is a corner against him, or some condition has arisen in the market or in labor which he has not accounted for. It is practically impossible for one man or one firm to be fully posted on all the branches of work entering into a large bridge or building contract. The consequence is he finds that he has a losing contract, a highly undesirable state of affairs, not only for himself, but for the purchaser. There is probably no engineer or owner who desires to see his contractor lose money; it is certainly bad for the contractor, and a source of great trouble to the purchaser, if not an actual detriment to the work. Of course, it is not right to assume that all contracts will be profitable, even if taken and prosecuted by specialists; all are likely to make mistakes; but it is fair to presume that fewer mistakes are made in one's own line of work than in something with which one is not familiar.

The subject has thus far been considered principally from the standpoint of the contractor, and the speaker has endeavored to show wherein it would benefit the contractor to take only his own kind of work. In order to bring this about it must be shown to the purchaser, or the engineer or architect who represents him, that he will benefit by dealing separately. The principal argument offered in support of the general contract system is the supposed advantage of having only one party to deal with, and the presumption that trouble among independent contractors on the same work will be avoided by having them all under one control. The first proposition practically includes the second, and, while it may avoid some clerical or office work, it surely does not avoid anything in superintendence or inspection; and the fact that the combining of a large contract under one head will eliminate a large amount of competition would seem to far outweigh a slight saving of detail in drawing up a few extra contracts or making a few extra vouchers for payment.

It is a fact that the general-contract method eliminates competition. As an example, may be quoted the bridge work for the State of New York. The bulk of this work consists of not very large bridges over the canals, some of them aggregating perhaps $50,000, but most of them much less. It is the invariable practice in the Department of Public Works to make one contract to cover each structure, and they nearly all involve a little concrete, a little excavation, a little embankment, and so on, together with the steel superstructure, which, in the case of lift-bridges, may be quite complicated. The consequence is that there is little or no competition in this State work, and in case they are so fortunate as to receive two or three bids, about half the time the bids exceed the appropriation, because excessive prices are put in for the little odds and ends of work which the bridge builder does not want, but has to take in order to get the steel-work.

A local contractor, knowing or being able to ascertain easily the conditions prevailing, could take care of these items well and economically, but he is practically debarred from bidding because he cannot bid on the bridge and cannot find any bridge company who will give him a price. The bridge companies, on the other hand, at least a good many of them, not wishing to be bothered with the substructure work, especially under present conditions, when there is plenty of more desirable work, do not prepare any estimate, and the result is as stated; there is practically no competition and the prices are excessive.

There is no doubt whatever that much better results would be obtained if this work could be divided into, perhaps, not more than two separate contracts. The speaker once took occasion to ask an official of the State why they adhered to this practice, and found that it is because when the laws making the appropriations are passed, they direct that such and such moneys be appropriated and "a contract" be entered into for the work. The officials feel that they are bound to adhere rigidly to the letter of the law. It seems to be nobody's business to change this form of wording. This is only a typical case. The speaker could quote many instances where, of his own knowledge, the method of combining different kinds of work under one contract has prevented competition and raised the cost.

It seems strange that among the chief adherents to this method is the United States, in its various departments, and the largest municipalities of the country. We scarcely ever find it among the railroad companies, who regard the economical aspect more carefully than public officials. The Navy Department, for example, in letting the contract for a building, will include all masonry, carpentry, steel-work, plumbing, etc., under one contract. This surely precludes a certain amount of competition, and presumably is an expensive method, for the reasons stated above. Some of the principal bridge companies have practically turned down Navy Department work, although quite desirable in itself; but it cannot be secured without taking much work which is not desirable, or else under a sub-contract, with its attendant disagreeable features.

Bids for Public Work are tendered by the city engineer of Toronto, Can., Mr. C. H. Rust, in competition with the regular contractors, with the result that during 1901 thirteen of his bids were the lowest, and were carried out by day labor under his supervision. The following table shows the saving to the city in the cost of paving during the year due to this practice:

Class of Pavement.	Length, feet.	City's bid.	Next. lowest bid.	Actual gain to city.
Macadam	694	$1,300	$1,369	$108.80
Macadam	362	850	915	43.61
Cedar block on concrete	108	295	345	56.27
Cedar block on tarred planks....	613	2,700	3,368	460.02
Scorla and granite.	602	5,765	6,445	1,060.96
Totals	$2,379	$10,910		$1,729 66

Portland Cement Concrete Pavements have been introduced on two minor streets in Grand Rapids. They are described substantially as follows by City Engineer L. W. Anderson: Briggs Court has a total width of 30 feet, with 23-foot roadway. The roadway has a 4-inch crown and a curb exposure of 5 inches. The upper end of the roadway was enlarged to a 30-foot radius to allow the turning of teams. Donald Street has an 18-foot roadway and 4-foot walks. The sidewalks consist of a 3¼-inch base and ¾-inch top; the pavement of a 6-inch base and 1-inch top. The concrete for the base consists of one part Portland cement, three parts sand, and five parts screened gravel, the particles ranging in size from 1 inch to ¼ inch in their largest dimensions. The top consists of one part cement and two parts sand. The following is from the specifications: "The concrete pavement shall be laid in alternate 6-foot sections, with at least a ¼-inch expansion joint at the curb, and a template-made joint at the crown. A coarse brush finish shall be given the surface." The contract prices for this paving, which aggregated 2,196 square yards, were $1.78 and $1.56 per square yard.

The Pennsylvania R. R. Bridge at Fifty-second Street, Philadelphia.

At the 52d Street station of the Pennsylvania Railroad in Philadelphia the tracks of the Schuylkill division diverge from the main line and diagonally intersect six freight tracks. In order to avoid a grade crossing and give a free passage to the passenger trains the in-bound trains will enter the station in a tunnel below main line grade, and the out-bound trains on a bridge above grade. The bridge superstructure is of open-hearth mild steel and includes two long plate girder viaduct approaches and a single pin-connected through span of 387 feet 10 inches on centers with Pratt trusses 20 feet apart on centers which have thirteen panels of 29 feet 10 inches each. The center panel has parallel chords 45 feet apart on centers; all the other panels have inclined top chords sloping down to a truss depth of 30 feet at the hips. The span weighs about 900 tons, and being designed for heavy traffic at high speeds, is proportioned for mass and rigidity to resist vibrations and deformations.

The lower chord is made up entirely of 10-inch eyebars, of which there are in the center panel four 1⅝ inches, four 1 15/16 inches and two 2 inches thick. The main diagonal ties are 10-inch eyebars from 1 5/16 to 2⅛ inches thick. There are counters in five panels and all of them are pairs of square rods with loop eyes and sleeve nut adjustments, except in the center panel, where they are stiff members riveted to gusset plates at the top and bottom of the vertical posts. The trusses are sway-braced in the usual manner in the transverse vertical plane at every panel point by intermediate horizontal struts at a uniform clear height of about 20 feet above the rail base, top lateral struts and diagonal X-bracing of single 3½x3-inch angles in the vertical panels between them. The lateral systems consist of angle X-braces in all the panels between the top and bottom chords. The track is carried at a grade of 0.9 per cent. on two lines of stringers 6½ feet apart. All the web members of the truss are packed inside the top chord sections, the diagonal ties being close to the jaw plates of the vertical posts, outside them when there is only one pair of bars in the panel and one pair outside and one pair inside when there are two pairs. The bottom chord pins have the main ties packed next to the jaw plates of the vertical posts and the counters inside the posts.

The top chords and end posts are of the regular rectangular trough section with closed sides and top and latticed bottom; they have a 36-inch cover plate and three 28-inch webs, the two outside ones being 27½ inches apart. The lower flanges of the bottom angles are reinforced with 5-inch plates, and the pins are on the center lines of the web so as to make a nearly balanced and symmetrical section. The chords are made in single panel sections about 30 feet long, and adjacent pieces have no direct bearing on each other. Their ends have half holes for the pins and are milled to a clearance of ⅜ inch. They are not, properly speaking, spliced at panel points, but the joints are covered by light outside field-riveted cover plates over the top plate and the bottom flanges and by projections of the outside web reinforcement plates which form jaw plates with full pin holes at one end only of each chord section, thus not locking the chord sections together. The webs are made up of full width plates with eleven lines of rivets and with narrower plates riveted on between the angle flanges. Both ends of each section of top chord are stiffened by transverse vertical diaphragms about 2½ feet from the pin centers which clear the vertical posts and main ties. The chord shown at U6-U5 has the same maximum cross section as that for U6-U6.

The vertical posts are all made with two built channels with their webs in longitudinal planes, their flanges turned in and latticed. At the bottom they project below the lower chord-bar heads and have wide, thick horizontal plates shop-riveted across their ends and field-riveted to the floorbeams to afford connections for the bottom lateral angles. Above the lower chord pin there is the usual transverse vertical diaphragm for the floorbeam connection, which in this case is made with 36 ⅞-inch rivets in two vertical rows The two vertical posts at U6-L6 have wide gusset plates riveted across their faces at top and bottom to form connections for the center-panel diagonal members or counters, which are I-shaped struts made with two pairs of 6x4-inch angles, latticed. One of them is made in a single continuous piece about 51 feet long, and the other one is cut to clear it at and spliced across the intersection by a pair of 14x13/16-inch flange cover plates nearly 6 feet long. These are shop-riveted to one part of the diagonal to form jaw plates, which are field-riveted to the other part of the same diagonal with 48 rivets and to the intersecting diagonal with 16 rivets. The ends of the diagonals are riveted to the vertical posts with 60 rivets each.

The chord pins are 8 and 9 inches in diameter and up to 50 inches long at L6. They are all made to project ½ inch beyond the eyebars at each end and have the ends finished with a concave cast disc 12 inches in diameter, chambered 1 inch deep on the side towards the eyebar and held in position by a nut on the end of a 1⅛-inch bolt which passes through them and the axis of the pin.

The intermediate floorbeams have the lower sides of the end sections of the web notched to clear the lower chord and extended above the top flange to form the connection to the vertical post. The web is reinforced by two side plates extending from the end to beyond the stringer connection and by a second pair extending from the end to beyond the joint to act as cover splices for the latter. The 30-inch stringers are seated on horizontal shelf angles and have 26 field rivets through their vertical flanges and the web of the floorbeam at each end. The stringers are made with a ⅝-inch web plate, four 6x4x⅝-inch flange angles and four 14x⅝-inch flange cover plates. Horizontal connection plates are field riveted to the insides of their top flanges to receive single 3x3½-inch zig-zag angles, and the bottom flanges are riveted to the lower lateral diagonals. The end floorbeam has square ends seated on pedestals extended from the shoes for the trusses. The top flange angles project to cross the inclined end posts to which they are riveted with bent connection plates and braced by bent horizontal longitudinal angles. The track is carried from the end floorbeams to the abutment masonry on brackets in the planes of the stringer webs which have their top flanges spliced to those of the end stringers by flange cover plates passing through slots in the floorbeam webs. The top lateral diagonals are I-shaped struts made with two pairs of 3½x3-inch angles, latticed, and field riveted at the ends between a pair of horizontal plates like jaw plates on the inner flanges of the top chords. One strut is continuous, and the other is out to clear it and spliced across the intersection by top and bottom flange cover plates shop-riveted to one half and field-riveted to the other half. At the intersection both struts have full web plates which are connected by four vertical plates, two of them bent to acute and two to obtuse angles corresponding to the angles between the struts and one of each shop-riveted to the end of each short diagonal so as to make projecting flanges, which are field-riveted to opposite sides of the web of the continuous strut.

The bottom lateral diagonals are T-shaped struts made of pairs of 6x4-inch angles shop-riveted together back to back, with the vertical flanges up and the horizontal flanges field-riveted at the ends to the connection plates at the feet of the vertical posts. One strut in each panel is made continuous, and the other is cut to clear it and spliced across the intersection with a 16x⅝-inch bottom flange plate shop-riveted to the under side of one of the short pieces and field-riveted to the other and to the intersecting strut. Pairs of short connection angles with their horizontal flanges up have their vertical flanges shop-riveted to the vertical flanges of the struts and their horizontal flanges field-riveted to the under sides of the bottom flanges of the stringers.

The portal bracing consists of a main strut connecting the hip joints of the two trusses, a parallel strut below it in the plane of the end posts, and three horizontal panels of X-braces between them, and has no knee braces. The main strut has a pentagonal cross section, as shown in the detail, with solid web plates on four sides and lattice bars on the fifth and narrowest side. The two sides in the planes of the top flanges of the top chord and end post are made of separate flat plates spliced by a narrow bent cover plate. These plates do not extend quite to the ends of the strut, but are spliced to short end sections which project beyond the edges of the strut and are field-riveted to the inner sides of the flanges of the top chord and end post. These plates also serve as gussets for the connection of the top lateral diagonals and the portal X-braces. The lower horizontal portal strut is simply a plate girder with two 4x3½-inch flange angles and a 26x5/16-inch web perpendicular to the axes of the end posts. Each end of the web is field-riveted to the end post web through a single bent plate. The X-braces between the horizontal struts have I-shaped cross sections made with two pairs of 3½x3-inch angles, latticed.

The shoes are special, in that each has, on the side next the bridge axis, an extension of the bottom plate with a pedestal on it having a wide top plate which serves for the seat of the end floor beam and the end lateral diagonal connection. Each shoe has three webs reinforced to give a total length of 9¼ inches pin bearing. The web plates are in the same planes as the web plates of the end posts and are cut through the center of the pin to clear them and leave only half holes except in the cases of the outside pin plates which project above the others and have full holes corresponding with the projecting jaw plates on the lower ends of the end posts on the opposite sides of the bearings, and with them serving to lock these members together to the end pins. The expansion shoes are seated on segmental rollers 12 inches in diameter and 4½ feet long with transverse grooves in the center to lock them to 2¾-inch ribs on the surfaces of the bottom plates of the shoes and the tops of the bed plates. Both ends of the rollers are connected by tapbolts to horizontal top and bottom side pieces. These are composed of 5-inch channels with their webs reinforced by 5x1-inch plates. The tapbolts are 1½ inches in diameter and 7 inches long, penetrate the roller 3 inches and have a 1⅞-inch shoulder 3/32 inch longer than the thickness of the roller frame. Outside the frame the bolt is turned down to 1¼ inches diameter and has a nut bearing on a 3x½-inch washer.

The 54x68-inch bed plate for the expansion end is 1¼ inches thick and has nine 6x¾-inch flats riveted to the upper surface for transverse bearings for the rollers. The bed plate for the fixed end is 14 inches high over all to compensate for the depth of the roller nest, and is made with a 50x68x1¼-inch bed plate, and a 48x¾x60-inch top plate separated by seven pairs of 12-inch 40-pound channels riveted together back to back. In the longitudinal center line of each bed plate there is a vertical 5x4-inch angle riveted to the web of each channel so that the outstanding flanges of angles on adjacent pairs of channels are in contact, back to back, and are shop-riveted together, making Z-shaped diaphragms stiffening and uniting the channel webs. Each bed plate is anchored to the masonry by four 1⅜-inch stone bolts.

The bridge was built according to the specifications of the Pennsylvania Railroad Company, Mr. W. H. Brown, chief engineer; Mr. W. A. Pratt, assistant to chief engineer and formerly engineer of bridges, and Mr. H. R. Leonard, now engineer of bridges and buildings. The superstructure was built at the Pencoyd plant of the American Bridge Company, Mr. Paul L. Wolfel, chief engineer.

The Output of Cement in the United States has doubled in the five years from 1897 to 1901. According to the Treasury Bureau of Statistics, the output in 1901 was 20,000,000 barrels.

The World's Coal Production, according to a British exchange, is 700,000,000 tons annually. During the past three years the United Kingdom has produced an average of 221,441,000 tons, and the United States 242,816,000 tons. The total of these two countries amounts to nearly five-sevenths of the whole world's production.

Among the Smokeless Cities of Europe, Berlin ranks very high, according to consular reports. This is in spite of the fact that Berlin is a busy manufacturing place, and is accredited to three conditions: The prevailing use of coke and briquettes; the intelligent construction of boiler furnaces and chimneys; and the high standard of skill that is maintained among firemen.

Letters to the Editor.

Residential Septic Tanks.

Sir:—I can hardly agree with the ideas advanced and being put in practice for the care of the sewage of Zion City as outlined in the paper prepared by Mr. Burton J. Ashley for the American Society of Municipal Improvements and published in your issue of the 11th.

It has been considered feasible and desirable to include individual septic tanks in the scheme of sewage disposal for isolated residences and institutions, but it hardly seems advisable or economical to adopt this system in a city or village where a large number desire sewer connections and where it is necessary to use a sewer system to carry off the effluent from the isolated septic tanks. It is easy to admit that with the individual septic tanks the cost of final disposal will be lessened, that the sewers may more easily be kept clean, that the grades may be safely made a little less and that the cost of construction and maintenance of the sewer lines proper may thus be lessened to a slight extent. But over against these advantages are set the cost of constructing the individual tanks, which, it would appear, would greatly overbalance the advantages gained by this individual system, and, in addition, the cost of inspecting and cleaning the separate tanks. Furthermore, serious objection must be raised against the location of a septic tank in every yard. It seems that it would be cheaper to put in an ordinary system of sanitary sewers, with the necessary flush tanks, etc., and at the outlet provide works to care for the sewage, according to the system best suited to the locality. It is commonly believed that one large plant can be operated and maintained for a much less sum than would be necessary to care for a large number of isolated tanks. It certainly could be operated with much less friction than would be encountered in compelling individual owners to properly construct and maintain separate plants.

If septic treatment alone will sufficiently purify the sewage, then the large municipal disposal works will require practically no attention—at the most, much less than it will be necessary to bestow upon the separate tanks. If further treatment than that given by the tank must be provided, a municipal plant will be required anyway and the septic treatment could be much better given at the outfall. Leaving out all considerations of convenience and finance, this system of individual septic tanks must be unsatisfactory from a sanitary standpoint. It is possible to construct water tight tanks of brick and concrete, but it is difficult and requires considerable care. That this care will be used in the construction of every tank is extremely doubtful, and so there will ensue the use of leaky tanks in a good many cases, with the resulting pollution of the subsoil, a very undesirable condition. With improved methods these cesspools or tanks can be cleaned out without producing any great nuisance, but it is a nasty job and one which it would be well to avoid, especially in the more closely built up sections where the tanks can not be advantageously located. With the large number of septic tanks proposed, it is extremely probable that some will not work properly, with the result that an offensive effluent will be produced which may so foul the combined effluents as to make the work of the other tanks of no avail. Conditions may be such at Zion City that this method is the proper one, but it is hard to imagine just what they are.

Bowling Green, Ohio, has adopted the scheme of placing catch basins in the house connections to the sewer system, for the purpose of keeping out the solid matter and thus putting off the day when it will be necessary to provide a sewage disposal plant; but it is understood that this scheme is only a temporary expedient to be followed until the demand for connections shall have reached such a point that it will be easy to secure the money necessary for disposal. The requiring of these separate catch basins is a tax on sewer connections and tends to keep down the number. This is undesirable, also, as it usually is difficult enough in the smaller places to compel connections to be made, without placing any special obstacle in the way.

Yours truly,

BENJ. H. FLYNN.

Columbus, O., October 17.

Concrete Blocks in the Buffalo Breakwater.

Sir:—I notice on page 578 of your issue of June 21, 1902, this paragraph at the end of the editorial on "An Interesting Concrete Structure:"

"It is apparently the opinion of Major Symons that one advantage arising from the fabrication of the (concrete) blocks was the avoidance of the depositing of concrete *en masse* under water. Inasmuch as the top of the cribwork substructure was but little below mean water level, the method of first making the concrete blocks and then putting them in place undoubtedly had substantial advantages. If any one thing has been established, however, by prolonged experience during the past eight or ten years, it is that under proper conditions the best of good results may be obtained from a proper deposition of concrete *en masse* under water."

The conditions of construction at the Buffalo breakwater are evidently not well understood by the writer of the article referred to. In all engineering structures the matter of appearance and finish must be kept in mind. A slovenly piece of work reflects no credit on the engineer having it in charge. The use of the concrete blocks in the Buffalo breakwater gives character and finish to the structure, and facilitates greatly the operations subsequent to their placing. It fell to the lot of the writer of this letter to build the first section of concrete superstructure on this breakwater. The depth of water on the substructure being only a couple of feet and the toe of the concrete having to rest on wood caused all the trouble which made necessary the use of concrete blocks. The concrete toe was exposed to the constant rise and fall of little waves from the surface of the lake. The material could not be put in so fast as to prevent these little waves from washing out all the mortar from the broken stone and gravel. The result was that during the first season's work many holes were formed under the parapet. Some of these holes were more than a foot high and extended back under the wall four or five feet. As I remember the work done during that first season, I doubt whether a length of three consecutive feet can be found in which the toe of the face of the parapet has not been more or less injured in the way mentioned. Every possible care was taken to protect this angle. The joint between the sheeting and the top timber of the crib was calked; and then the two faces were lined with felt. The concrete was placed most carefully and with the least possible disturbance, but the relentless plashing of those little waves went on incessantly and finally triumphed over all the ingenuity of those who tried to vanquish it.

The holes mentioned above had to be filled as best they could. The most successful method accomplishing the work was to pack them full of small bags filled with concrete, the outside of the bags being thickly smeared with quick-setting cement mortar. The result was effective but unsightly. A cut-stone masonry face was tried, but it was found to be prohibitive in cost. Then the concrete blocks were authorized. They had a double advantage: first, they preserved the face of the work; second, they formed a small breakwater behind which the concrete work could be carried on during many days when a little roughness of the lake would otherwise have put a stop to operations.

Two points must be considered in criticising such admirable work as that of Major Symons: concrete will not bond with wood; and a clean edge cannot be put on concrete in a sea way.

Yours truly,

F. A. MAHAN,

Major of Engineers, (Retired).

Paris, September 24.

The New East River Bridge Cables.

With the approaching completion of the main cables six of the seven principal divisions of work on the great East River bridge will have been nearly or quite finished. The building of the caisson piers, of the main towers, of the anchorages, of the four shore spans, of the approaches and of the cables leaves only the roadways and trusses to be suspended between the main towers. The designs for this work have been so carefully elaborated and the contracts so long made that with all the preparations complete for its execution it should soon be possible to predict with confidence the time when the bridge will be ready for use, barring only the direct and indirect delays from labor troubles, which apparently may arise in spite of every precaution.

The four main cables, which are the largest in the world and have been built at the most rapid rate, are practically completed and adjusted and are now receiving the final covering, which, although not an element of their functions in the bridge, is expected to thoroughly protect and preserve them for many years. Each of the four main cables is about 18 inches in diameter, 3,000 feet long and weighs 2,500,000 pounds. It is composed of 10,397 straight steel wires and has an ultimate strength of about 50,000,000 pounds. The wires, about 3/16-inch in diameter, were received in 4,000-foot lengths and their ends were spliced with sleeve nuts to make them continuous throughout each of the 37 strands. They were pulled across the river in double lengths and looped over the end pins like yarn in a skein. After adjustment for length, position and stress they were solidly compacted into a cylinder, bound and covered with a mixture of oil and graphite. They are to be covered with a water-tight cylindrical steel shell, but it has just been decided to interpose a special waterproof covering inside the shell, and a $50,000.00 contract for this has been awarded to the John A. Roebling's Sons' Company, who have built the cables. Waterproofed duck will be cut in strips 7 inches wide and wrapped spirally around each cable from end to end. A second and a third wrapping will follow and then the steel shells will be put on and the cables will be ready to receive the suspended structure.

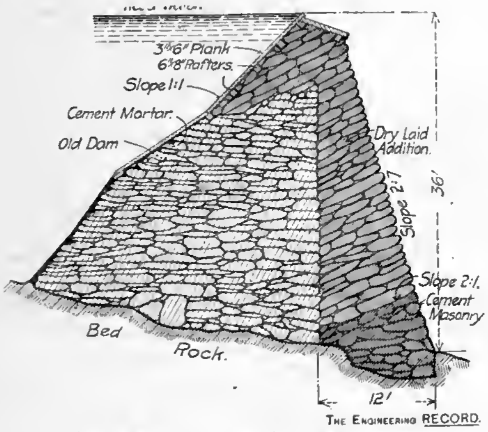
The Mileage of Electric Railways in the United States is now between 24,000 and 25,000 miles, according to a statement made by President Vreeland at the recent convention of the American Street Railway Association. The total capital invested is nearly $2,000,000,000. Eleven years ago there were only 1,800 miles of such railways representing an investment of about $75,000,000.

Reconstruction of a Stone Dam at Roswell, Ga.

The stone dam at Roswell, Ga., a section of which as finally reconstructed is shown in the accompanying cut, was first built some fifteen years before the civil war, and was then used in connection with a regular over-shot water wheel. It was built of dry laid stone, the water face being laid a few inches deep in either a cheap form of Rosendale cement or a very good quality of lime mortar. The old stonework was largely of a flat, stratified formation and was laid in horizontal courses. It is stated that in the body of the dam the stone was very poor, being little better than shale.

About ten years ago the old dam was overhauled and patched. The water slope at the spillway was coated with cement mortar, in which a plank face was laid. This dam had a sheer drop at the spillway of slightly over 27 feet and a depth of spillway of about 5 feet. The length of the spillway was the same as at present, 138 feet. The greatest thickness of the old dam at its base was roughly 30 feet.

As finally reconstructed under the direction of Messrs. Collier & Brown, consulting engineers, Atlanta, a dry rubble addition was placed on the downstream face of the dam, resting on a solid masonry foundation laid on bed rock. The mortar used on the work was composed of one part Atlas cement to three



Section through Spillway.

parts sand. The masonry foundation course was laid with its upper surface sloping toward the center of the dam in the ratio of two horizontal to one vertical, and the new dry laid stonework was placed upon this in irregular parallel courses. The crest of the dam was raised above its former level about 6 feet, and a face of 3x6-inch yellow pine planking was put on the water face and joined to what remained of the old timber face by a watertight joint. The length of the spillway is 138 feet and its depth 5 feet. The total length of the dam is 251 feet. Two head-gates of oak timber, 2 feet 8 inches by 6 feet in size are provided, and two sluice gates about 3 feet square can be used to draw off the pond.

Time was the most important consideration in the reconstruction of this dam. It was necessary to shut down the mill of the Roswell Manufacturing Company, which utilized the power developed, on account of repairs and replacements in the plant, and the company did not wish the work on the dam to cause any further delay. In order to keep the work moving at its fastest rate, six quarries were opened along the shores in the vicinity of the dam. Of these, five were in continuous operation. Two fed to the dam by means of an overhead cable conveyor stretched across the dam site from bluff to bluff, a distance of 500 feet. Three others were connected to the dam by tram lines, and from one the stone was floated down the stream in scows.

The work on the downstream face of the dam was carried on with the dam full, the water level being kept below the spillway by means of the sluice gates. The work on the crest of the dam and on the gates was carried on while the mill was shut down for its own repairs and the pond drained, thus causing no delay in the operation of the mill. The contractors for the work were Sullivan Brothers, and Lewis White, of Roswell.

As the dam at Roswell withstood the floods of last winter, which destroyed the dams at Columbus, Ga., Anderson, S. C., and elsewhere, it is to be assumed that the design is of sufficient strength to withstand the greatest flood likely to occur in that region. The foregoing notes have been prepared from information and drawings furnished by Messrs. Collier & Brown.

Personal and Obituary Notes.

Mr. Robert Maxson Greene, Assoc. M. Am. Soc. C. E., has been added to the force of the Director of Works of the Louisiana Purchase Exposition for structural engineering work.

Messrs. Robert Stockton and Frank Moses, assistant to the president and chief engineer, respectively, of the South Jersey Gas, Electric & Traction Co., at Camden, N. J., have resigned.

Lieuts. William Kelly, John R. Slattery and Paul S. Bond, Corps of Engineers, U. S. A., have been ordered to the Washington barracks for duty with the Third Battalion of Engineers.

Mr. H. S. Burroughs has withdrawn from the firm of Ballantyne & Evans and has opened an office at 27 William Street, New York, for the practice of electrical and mechanical engineering.

Mr. Reed R. Lewis has left the field of general consulting practice to accept the position as superintendent of The Century Architectural & Engineering Co., Real Estate Trust Building, Pittsburg.

Mr. Rudolph Hering has been engaged by the Board of Health of Bridgeport, Conn., to determine the condition of the city's reservoirs and advise regarding the establishment of a filter plant.

Mr. Emil Kuichling has been engaged by the Street and Water Board of Jersey City in connection with proceedings that are to be instituted to compel the Jersey City Water Supply Co. to build a dyke at the Boonton reservoir, according to the board's own plans.

Mr. N. A. Christensen has resigned as general superintendent of the Christensen Engineering Co., of Milwaukee, to manufacture air compressors for all purposes except air brakes, this work being still continued by the company, of which he will remain consulting engineer.

Messrs. G. H. Benzenberg, M. Am. Soc. C. E., of Milwaukee, Allen Hazen, M. Am. Soc. C. E., of New York, and William G. Clark, Jun. Am. Soc. C. E., of Toledo, have been employed by the water-works board of Toledo, O., in connection with the selection of a water supply for that city.

Mr. Albert S. Crane, M. Am. Soc. C. E., has resigned as chief engineer of The Lake Superior Power Co., Sault Ste. Marie, Ont., to take charge of the water-power development of the Chicago drainage canal at Lockport and Joliet, becoming one of the assistant chief engineers of the Chicago Sanitary District.

Col. Allan C. Bakewell, who was recently elected president of the Sprague Electric Co., has long been identified with the electrical industry. He was vice-president and general manager of the old Interior Conduit & Insulation Co., which was absorbed by the Sprague Electric Co., some years ago, and previous to his present office, was for three years second vice-president and general manager of the Sprague Company. Mr. D. Clarence Durland, for the past three years assistant general manager of the company, has been elected its second vice-president.

The following candidates for membership in the American Society of Civil Engineers were announced elected October 15. Associate, Merrill Watson, New York City. Juniors: E. M. Adams, Washington, D. C.; A. F. Armstrong, Ogdensburg, N. Y.; H. J. M. Baker, Port Townsend, Wash.; H. E. Boardman, New York City; O. C. Edwards, Jr., Steubenville, O.; J. W. DuB. Gould, Yonkers, N. Y.; L. T. Haney, St. Elmo, Va.; E. C. Heald, Phœnixville, Pa.; S. B. Hill, Ithaca, N. Y.; A. R. Holliday, New Castle, Pa.; S. C. Hulse, Ithaca, N. Y.; R. C. Kimball, Evart, Mich.; Kieffer Lindsey, Columbus, Ga.; H. P. McDonald, Jr., Jersey City, N. J.; J. H. Madden, New York City; D. H. Ray, New York City; R. H. Sabin, Sherman, Tex.; C. H. Snyder, Johnstown, Pa.; W. P. Taylor, Philadelphia, Pa.

George H. Mendell, M. Am. Soc. C. E., Col., Corps of Engineers, U. S. A., retired, and president of the Board of Public Works of San Francisco, died October 19. He was graduated from the Military Academy at West Point in the class of 1852, as a second lieutenant of the topographical engineers, and remained in the service throughout the Civil War, becoming finally colonel, Corps of Engineers, in 1886. For gallant and meritorious services, particularly at the siege of Petersburg, Va., and in the defenses of Baltimore, he was breveted colonel in 1865. Most of his work for the engineers' corps, both before and after the war, has been in California, with the exception of about five and one-half years as assistant professor in the Military Academy; and since 1876 he has in his civil capacity been identified from time to time with considerable municipal work of San Francisco. From 1878 to 1880 he was consulting engineer of the State of California.

The Intramural Railway at the Louisiana Purchase Exposition will be a third-rail road 9 2/3 miles long, traversing the grounds in three loops. The elevated portions will be wooden viaducts.

A 750-Horse-Power Steam Turbine, to be made by the General Electric Company, is said to have been ordered by the Massachusetts Electric Companies for their station at Newport, R. I.

Timber Dams generally have an indefinite life, but Mr. J. M. G. Watt, M. Am. Soc. C. E., has recently pointed out that it is just the few exceptions that cause great trouble; he has been compelled to tear out thousands of feet of good timber in order to get down to the rotting sticks threatening a structure's stability. Hence a concrete dam is preferable. Where timber must be used, it is sometimes advisable to build several courses in shallow water near the shore and float them into position; he has followed this plan with cribs 250 feet long, 50 feet wide and 8 to 10 feet high. He has found 10x10-inch sticks the most economical, and builds his pens on 10-foot centers. Butt joints are used everywhere. The sheathing on the upstream face is a layer of 3-inch plank covered by one of 2-inch plank, breaking joints; if placed carefully close together they do not need calking. The top layer is in two courses, the upper section being short so that when it is replaced it is unnecessary to draw the pool down more than 12 to 15 inches.

CONTRACTING NEWS

OF SPECIAL INTEREST TO

CONTRACTORS, BUILDERS, ENGINEERS AND MANUFACTURERS

OF ENGINEERING AND BUILDING SUPPLIES.

For Proposals see page xv, xvii, xviii and xxvii.

WATER.

Bridgeport, Conn.—The Bd. of Health has engaged Rudolph Hering, of New York City, to examine the condition of the reservoirs from which the city water is obtained and advise as to the best course for the city to pursue concerning a filtering plant.

Newport, R. I.—See "Government Work."

Paulsboro, N. J.—Consulting Engr. I. S. Cassin, Jr., 2906 Girard Ave., Philadelphia, writes that the following contracts were awarded for water works supplies, machinery, etc. (bids opened Oct. 11), successful bidders all of Philadelphia: R. D. Wood & Co., 330 tons 8-in., 6 in. and 4-in. pipe at $32, specials, 3 cts. per lb. $11,160; also valves and valve-boxes, $322.75; J. Thompson & Co., fire hydrants, $938.90; W. H. Boardman, pipe laying, $3,100; A. H. Haig, standpipe, etc., $4,900; Otto Gas Engine Wks., pumping machinery and plant, $2,440.

Fishkill, N. Y.—E. H. Sheaff, Supt. Fishkill & Matteawan Water Co., writes that it is proposed to lay 4,100 ft. 6-in. and 1,200 ft. of 4-in. water mains; also an additional supply has been ordered by the directors Wm. S. Bacot, Engr. in Charge.

Bradford, Pa.—Bids are wanted by the Water Comrs. until Oct. 27 for furnishing 2,000 ft. of 8-in. and 150 ft. 4-in. C. I. pipe, 6,000 lbs. specials, 6 2-nozzle hydrants and necessary fittings and valves; also for trenching and laying pipe. A. F. Bannon, Jr., City Engr.

Tarrytown, N. Y.—J. W. Ledoux, Ch. Engr. of the American Pipe Mfg. Co., Philadelphia, Pa., writes that said Co. on Oct. 22 awarded the contract for the Pocantico River pumping station, to be erected 3 miles north of Tarrytown, to Moffatt, Hewitt & Norris, 12 E. 23d St., New York City.

Pittsburg, Pa.—Wm. Glyde Wilkins, Engr. and Architect of Pittsburg, is reported to have awarded contracts to H. F. Stark, of Greensburg, for 2 reservoirs, one to be built for the Southwest Water Co., between Connellsville and Uniontown, with 6,000,000 gal. capacity, the other to be built at Hecla for the Hecla Coke Co., 9,000,000 gal. capacity. Total cost about $60,000.

Tonawanda, N. Y.—The lowest bid received by the Village Bd. for a pumping engine to be installed in the Tonawanda water works station on Goose Island is stated to have been from the Holly Mfg. Co., of Lockport, at $26,000 for an engine of 8,000,000 gal. capacity, or $21,000 for an engine of 6,000,000 gal. capacity.

Jamestown, N. J.—By a vote of the people of this city bonds will be issued on Jan. 1 for $600,000 to buy the plant of the Jamesotwn Water Supply Co.

Waynesboro, Pa.—The Waynesboro Water Co. is reported to have voted to issue bonds to the amount of $75,000.

Brooklyn, N. Y.—Comr. Monroe, of the Dept. of Water Supply, Gas & Electricity, has asked for an appropriation of $25,000 for the purchase of meters for the Boroughs of Brooklyn, Queens and Richmond.

Lyons, N. Y.—The Bd. of Aldermen is considering the question of municipal ownership of the water works.

Watertown, N. Y.—City Engr. C. O. McComb and Frank A. Hinds, Engr. of the Water Comrs., are reported to be making surveys to determine the feasibility of obtaining a water supply for Watertown from Crystal Lake.

New Hope, Pa.—G. C. Gohanear, of Carlisle, is said to be desirous of establishing a water plant for this town.

Wilmington, N. C.—A charter has been granted by the State to the Cape Fear Rice Co., which will operate a rice mill at Wilmington. Capital stock, $200,000. Stockholders: H. Burton Anderson, John H. Gore and Jas. W. Sneeden.

Columbus, Ga.—The Columbus Water Works Co. has made an offer to improve its plant at an estimated cost of $100,000 provided the city will withdraw the proposition to issue bonds for the construction of a municipal plant or the proposed issue of said bonds be defeated at the Dec. election.

Tabor, Ia.—Town Clk. A. A. Falling writes that on Oct. 14 it was voted to construct water works at a cost of $6,500.

Bennett, Ia.—The Town Clk. writes that a vote has been taken in favor of constructing a system of water works.

Toledo, O.—The Water Works Bd. has approved a resolution to construct a second water main across the river to the East Side, said main being a continuation of the 30-in. Erie St. main. Estimated cost, $20,000.

Bucyrus, O.—The City Council has voted to extend the water mains on Clark and W. Warren Sts.

Forest, O.—City Clk. Harry E. Moore writes that an ordinance has been passed providing for the construction of water works and an electric light plant, to cost $25,000.

Fremont, O.—Bids will be opened Nov. 7 by the Water Works Trus. for the installation of an air lift plant at the local pumping station to pump several wells.

Sullivan, Ill.—Bids are wanted Nov. 3 for the erection of a brick building at the city water works for the boiler and machinery of water works. D. G. Lindsay, City Clk.

Mallard, Ia.—Press reports state that this city is to build a new system of water works.

Columbus, O.—Bids are wanted Oct. 28 for the construction of a 2-span steel truss aqueduct, timber trunk, having a total length of 106 ft., to be built one mile south of St. Mary's, on the Miami and Erie Canal, crossing St. Mary's River. Chas. E. Perkins, Ch. Engr. of Pub. Wks.

Oelwein, Ia.—Press reports state that the City Council has decided to purchase a new pump of 1,000,000 gal. capacity.

Lansing, Ia.—Geo. C. Morgan, of Chicago, Ill., is reported to have prepared plans for a reservoir, pumping station, etc.

Worthington, O.—The City Council is considering the matter of constructing water, sewerage and light plants.

Ottawa, O.—Press reports state that a vote has been taken in favor of the construction of water works and a sewerage system.

Newark, O.—The City Council has passed an ordinance authorizing the issue of $300,000 bonds for the construction of a new water works system.

Youngstown, O.—The Water Works Trus. have submitted a proposition to Council for the expenditure of $250,000 for a filtration plant.

Scranton, Miss.—This city has voted to sell its water works and electric light system to Dr. L. S. Anderson, of Moss Point, Miss.

Mena, Ark.—City Engr. S. B. Robertson writes that municipal water works are to be built at a cost of $25,000. Time for receiving bids not yet fixed. J. H. Hamilton, Chmn. Bd. Water Comrs.

Purcell, Ind. Ter.—D. Carter, Pres. of the Purcell Water Co., writes that a system of water works will be constructed at a cost of $45,000. Bids not yet called for.

So. McAlester, Ind. Ter.—City Clk. Gus. A. Gill writes that on Oct. 18 it was voted to issue $150,000 bonds for the construction of water works and sewerage.

Louisville, Ky.—Bids are wanted by the Louisville Water Co. until Dec. 20 for 30,000,000-gal. and 24,000,000 gal. pumping engines, as advertised in The Engineering Record.

Birmingham, Ala.—The Birmingham Water Works Co. has signed the agreement with the city to establish a filtration plant at North Birmingham within 12 months, and one on Shades Mountain for the Cahaba supply, to be completed within 18 months.

The Hawkins Spring Water was recently incorporated, with a capital of $150,000, for the purpose of operating water works in Jefferson County and elsewhere. Morris Adler, Pres.; S. E. Thompson, Vice-Pres., and S. M. Adler, Secy.

Guthrie, O. T.—W. T. Roberts, of Austin, Tex., is one of the incorporators of the Otter Creek Irrigation Co., which was recently organized under the laws of Oklahoma, with a capital stock of $1,000,000, for the purpose of constructing an irrigation system in the southwestern part of Oklahoma, bordering on Tex. M. M. Hankins, of Quanah, Tex., is also interested.

Redding, Cal.—J. B. Devereux, of Denver, is reported to have purchased water rights along Brandy Creek with a view to supplying this city with water.

Basin, Wyo.—The Bluff Canal Co., which will operate at Basin, has been incorporated, with a capital of $25,000.

Cody, Wyo.—Press reports state that the Cody canal is to be extended 15 miles for the purpose of reclaiming 12,000 acres of land.

La Junta, Colo.—Bids are wanted Nov. 1 by the Otero Irrigation Dist. for excavating about 350,000 cu. yds. of earth and rock along the line of Otero Canal, and for constructing a timber dam across Arkansas River. M. F. Miller, Secy. F. T. Lewis, of La Junta, Ch. Engr.

The La Junta Irrigation Co. has been incorporated, with a capital of $5,000, by Clyde Turnbull, Bert Harris and G. R. Markey, Arapahoe, Neb.

Wilbur, Wash.—Press reports state that a water system is to be constructed.

Edgemont, S. D.—This town is to have a system of water works for fire protection and domestic use.

Arlington, S. D.—The citizens are said to have voted bonds for the sinking of an artesian well.

Sterling, Colo.—Town Clk. C. L. Goodwin writes that on Oct. 11 it was voted to issue $63,000 bonds for the construction of a gravity water works system.

Ordway, Colo.—Town Clk. and Recorder Wm. Edgar writes that on Oct. 10 it was voted to construct water works.

Central City, Colo.—City Clk. and Treas. M. K. Sullivan writes that the city proposes to construct a reservoir at a cost of $30,000. Contract for excavating already let at 75 cts. per cu. yd Contract for walls and cement work will be let as soon as weather permits in the spring. Geo. W. Schneider, Engr. in Charge.

Phoenix, Ariz.—The water storage conference committee of representatives of the various irrigation interests in this valley have adopted the report of the Executive Committee charged with the work of outlining a plan for harmonizing all interests in order that the Government may proceed with the building of a storage reservoir at Tonto Basin site. The plan provides for a merger corporation known as the Water Users' Asso., to deal directly with the Government, guaranteeing payment for the dam in 10 years and the proper distribution of water. Estimated cost of dam, $2,500,000, according to local press reports.

Columbia City, Wash.—Municipal Water Works bonds to the amount of $5,000 have been sold.

Montreal, Que.—The Finance Com. has decided to purchase 3 new boilers for the low level pumping station. Estimated cost, $15,000.

SEWERAGE AND SEWAGE DISPOSAL.

Bristol, R. I.—The Council has authorized the expenditure of $7,000 for sewer work.

Worcester, Mass.—The Com. on Sewers of the City Council has voted to build a sewer in Hollywood St.

Boston, Mass.—The following bids were opened Oct. 1 by the Metropolitan Water and Sewerage Bd. for Ward St. pumping station, Section 77, high-level sewer, Roxbury; bidders all of Boston.

Bidder.	Foundations and Connections. Excav., 20,000 cu. yds.	Con. Mas., Amer., 100 cu. yds.	Boulder Cement Con. Mas., Amer., 500 cu. yds.	Con. Mas., Port., 7,000 cu. yds.	Rolled Beams & Ransome Twisted Steel, 70,000 lbs.	Found. & Connec. Br. Mas., Port. 700 cu. yds.	Cut Gran. Stone, 150 cu. yds.	Superstructure complete.	Totals.
Connery & Wentworth......	$1.35	$5.50	$3.80	$6.95	$0.03¾	$22.00	$61.00	$149,187	$254,462
McNeil Brothers	1.35	6.30	7.35	8.40	0.04	18.00	55.00	164,509	278,264

Big Valley, Tex.—The Big Valley Canal & Irrigation Co. has been incorporated, with a capital stock of $5,000, by J. L. Ratekin, W. H. Oglesby, C. Ballard and others.

Lancaster, Tex.—The Attorney General, Austin, Tex., has approved an issue of $10,000 city of Lancaster water works bonds.

Victoria, Tex.—The Council has under consideration the installation of a filter at the water works. Estimated cost, $8,000.

Waco, Tex.—The Colorado Power & Mfg. Co. of Waco, has been incorporated, with a capital of $12,000, to construct and maintain dams, lakes, reservoirs, canals, etc., for irrigation and milling purposes. Incorporators: N. N. Seley, R. H. Chatham and others.

Vicksburg, Miss.—Local press reports state that the city is desirous of purchasing the water works plant and constructing a system of sewerage.

Gonzales, Tex.—A vote is to be taken on the proposition to issue $32,000 bonds for the establishment of a municipal water plant.

Kansas City, Mo.—The Bd. of Pub. Wks. has approved ordinances calling for appropriations of $9,000 for improvements at Turkey Creek pumping station, and $6,000 for repair of pipes around the station.

Enid, Okla. Ter.—The proposition to issue $15,000 bonds to extend the water mains and $25,000 to build a sewer system is reported to have carried.

Golden, Colo.—The contract for constructing a gravity water works system from Beaver Brook to Golden is stated to have been awarded to M. B. McDonald, of Denver, for $95,000.

Bridgeport, Neb.—The Beerline Irrigation Co., with headquarters at Bridgeport, has filed articles of incorporation. Capital, $10,400. Incorporators: Geo. W. Beerline, John Beerline, Edgar D. Smith and others.

Canajoharie, N. Y.—Village Clk. J. C. Melick writes that on Oct. 16 it was voted to construct a sewerage system at a cost of $36,000.

Washington, D. C.—Bids are wanted Nov. 15 for constructing a portion of the Low Area Trunk sewer, as advertised in The Engineering Record.

Buffalo, N. Y.—Bids are wanted Oct. 31 for the construction of 10, 12 and 15-in. tile sewers in several streets; also for the construction of 48 to 27-in. brick sewer in Mumford Ave. Francis G. Ward, Comr. Dept. of Pub. Works.

Brackenridge, Pa.—City Engr. E. E. Maurhoff, of Tarentum, writes that the contract for sewer construction (bids opened Oct. 20) has been awarded to Hastings & Walsh, of Charleroi, Pa., as follows: Concrete, $5; manholes, $45, complete; receiving basin, $60; lumber per M., $22; 2-ring brick sewer laid in cement with terra cotta invert, 3,488 ft. 4 ft.x5 ft., at $5.40 per lin. ft.; terra cotta pipe for connections, 36-in. at $4, 24-in. $1.50, 18-in. $1.20, 15-in. $1, 12-in. 80 cts., 10-in. 65 cts., and 8-in. 50 cts.; total, $19,757. Other bids received were as follows, the prices per lin. ft. for brick sewer and the totals being given respectively: Luster Construction Co., Tarentum, $7.33, $34,905; J. H. McQuade, Pittsburg, $5.70, $20,998; Keeling & Ridge, Pittsburg, $7.75, $28,084; J. B. Sheets & Co., Pittsburg, $6.28, $23,007; Ott Bros., Pittsburg, $5.65, $20,733; Thos. Sweeney & Co., Pittsburg, $6.75, $24,596.

Butler, Pa.—The Council has passed an ordinance providing for the construction of a sewer in Mercer St.

Oneida, N. Y.—City Engr. W. R. Vedder writes that bids are wanted Nov. 11 for the construction of a trunk sewer, 8-in. to 20-in. vitrified pipe to be used. Estimated cost, $25,000.

McKeesport, Pa.—The Common Council has passed ordinances for sewers in Acheson and Powderly Sts. and Crooked Run.

Massena, N. Y.—Village Clk. J. W. Webb writes that at the recent election it was voted to construct sewers; bids for same will soon be received; work to be started early in the spring. Cost, $20,000 to $40,000.

Yonkers, N. Y.—The contract for constructing a sewer in McLean Ave. and S. B'way has been awarded to Molloy & Murray for $11,500.

Comr. Cooper has reported to the Common Council, placing his preliminary approximate estimate of the cost of constructing a drainage tunnel, 7 ft. in diameter, to provide sewage facilities for the upper portion of Saw Mill River Valley, including an outfall into the Hudson River, at $122,950.

Jamesburg, N. J.—Bids are wanted Nov. 5 for constructing sewers at the State Home for Boys. Edw. Spaeth, Pres. Bd. of Trus., 742 Broad St., Newark, N. J.

Jersey City, N. J.—The Street & Water Bd. has confirmed specifications for the proposed sewer in Harrison Ave. The city will pay $5,635, which is 4/5 of the total cost of said improvement.

Waukegan Ill.—Mayor F. Finer writes that the following bids were opened Oct. 10 for the construction of a system of sanitary sewers, the work, which calls for sewers in numerous streets, includes *a*, 31,173 ft. of 18-in. to 6-in. vit. pipe sewers, from 15.4 ft. in depth to 4 ft. in depth; *b*, 168 manholes; *c*, bulkhead and outlet with 200 ft. of cast iron pipe, 12-in. in diameter; *d*, 20 combined flush tanks; *e*, lumber left in place per M; total: Jas. Cape & Sons, Racine, Wis., *a*, $2.80 to 40 cts.; *b*, $10 each; *c*, $800; *d*, $40 each; *e*, $50 per M; *f*, $23,314. Reichert Const. Co., Racine: *a*, $2 to 35 cts.; *b*, $30 each; *c*, $150; *d*, $70 each; *f*, $25,230. John W. Barker, Melrose Park, Ill.: *a*, $1.29 to 32 cts.; *b*, $32 each; *c*, $2,603; *d*, $125 each; *e*, $25 per M; *f*, $27,073; Chas. T. Bartlet, Evanston, Ill.: *a*, $1.30 to 39 cts.; *b*, $20 each; *c*, $600; *d*, $40 each; *e*, $24 per M; *f*, $26,990. W. H. Harris, Terre Haute, Ind.: *a*, $1.50 to 45 cts.; *b*, $37.50 each; *c*, $1,000; *d*, $75 each; *e*, $25 per M; *f*, $27,684.

Toledo, O.—Bids are wanted Nov. 3 for the construction of a 10 and 12-in. pipe sewer in alley west of Hoag St., also for a 10-in. pipe sewer in alley between E. B'way and Essex St. Chas. H. Nauts, City Clk.

Millburn, N. J.—The following bids were opened Oct. 20 for building a sewerage system. Alexander Potter, New York City, Ch. Engr.

The two sets of figures show the difference in cost in providing a sewer for Section 6 of a capacity sufficient to permit the admission of Morristown, Morris Plains, and Madison to the Joint Trunk Sewer. This section is the last section of the Joint Trunk Sewer to be let until it is definitely determined whether or not Morristown and the other cities across the South Mountain will connect up with this Joint Sewer. The sewer throughout has been made large enough for the admission of these municipalities.

The contract for Section 4 of the Joint outlet sewer has been awarded to John P. Hall, of Jersey City, for $47,553. For bids received for Section 4 see The Engineering Record of Oct. 4.

Griffin, Ga.—Local press reports state that this city proposes to have surveys and estimates made for the construction of a sewerage system.

Logansport, Ind.—City Engr. Walter A. Osmer writes that the extension of the sewerage system asked for, involving an expenditure of $175,000, will probably be granted.

Burlington, Ia.—The following bids are the lowest received Oct. 6 for sewer construction: Ash St. sewer, Stewart & Hayden, at 80 cts. per lin. ft. complete; Central Ave. sewer, Burlington Const. Co., $2.45 per lin. ft. for sewer complete, not including appurtenances extra specials; $77.25 for catch basins, including connections, and $45 for manholes; North Oak St. sewer, Geo. Kriechbaum, at $1.75 per ft. for sewer complete. Emmet Steece, City Engr.

Des Moines, Ia.—The City Council has ordered the construction of the North Des Moines sewer, which is to be built all of 12-in. pipe.

Port Huron, Mich.—Bids are wanted Nov. 1 for the construction of a brick and tile main sewer in Beard and 20th Sts. R. D. O'Keefe, Supt. of Pub. Wks.

Milwaukee, Wis.—Sewer bonds to the amount of $100,000 have been sold by this city.

The estimated cost of changing sewers in the 18th Ward for track depressing is placed by the City Engr. at $40,000.

Bond Hill, O.—The Village Council has decided to issue $40,000 bonds for sewer construction.

Minneapolis, Minn.—The City Engr. has been authorized by the Council to purchase 200,000 brick for sewer construction.

Dayton, O.—The Co. Engr. has been directed to make surveys and estimate the cost of constructing a sewer in Harrison Township.

Kalamazoo, Mich.—The contract for constructing a concrete sewer in Vine St. has been awarded to H. P. Streicher, of Toledo, O., for $9,487.

Cass Lake, Minn.—The contract for the extension of the sewer system is stated to have been let to Pastoret & Martin, of Two Harbors, for $7,474.

Oelwein, Ia.—The City Council has passed resolutions for the construction of certain sewers.

Cincinnati, O.—The Bd. of Pub. Service has approved City Engr. Stanley's plans for the construction of a trunk sewer in the ravine east of Torrence Road. Estimated cost, $10,753.

Akron, O.—Bids are wanted Nov. 1 for constructing local sewers in portions of 6 streets and a main trunk sewer in Sewer Dist. No. 9 in Meadow Alley. Bids will also be received Nov. 15 for constructing a main trunk sewer in Sewer Dist. No. 9 in Howe St. Chas. H. Isbell, Clk.

Worthington, O.—See "Water."

Ottumwa, Ia.—City Engr. J. T. Brady, writes that no bids were received Oct. 20 for the construction of a portion of South Ottumwa trunk sewer, and new bids have been asked until Nov. 3.

The 6-ft. brick sewer across Richmond Ave. recently destroyed during heavy rain is to be soon replaced by culvert of ample size.

Ottawa, O.—See "Water."

Vicksburg, Miss.—See "Water."

Gueydan, La.—Engr. Chas. D. Pabbitt is said to be making a survey of White Lake section with a view to draining and reclaiming large tracts of marsh land.

St. Louis, Mo.—Ordinances will probably soon be passed for the reconstruction of sewers in alleys between Pine and St. Charles Sts., 9th and 12th Sts. Estimated cost, $50,000.

Smithville, Tex.—A stock company is being organized here to put in a sewerage system for the city.

So. McAlester, Ind. Ter.—See "Water."

Louisville, Ky.—The ordinance providing for a $5,500,000 bond issue for streets and sewers is stated to have been passed by the Council.

Ft. Smith, Ark.—City Engr. T. A. Bayley writes that the city will receive bids Oct. 31 for the extension of about one mile of sewers; cost about $10,000.

Enid, Okla. Ter.—See "Water."

Fresno, Cal.—In a recent report to the Bd. of City Trus., City Engr. I. Teilman recommended the construction of a 30 and 36-in. brick intercepting sewer and a septic tank 60 ft. wide, 8 ft. deep and 500 ft. long, to be built of concrete. Estimated cost, $55,000.

Grand Forks, N. D.—The Co. Drainage Comn. is stated to have awarded the contract for the Levant ditch, which will be 13 miles in length and about 20 ft. wide, to P. McDonnell for $28,000.

Montreal, Que.—Local press reports state that $8,000 has been voted for the continuation of St. James St. sewer.

BRIDGES.

Springfield, Mass.—The Special Comn., consisting of John W. Corcoran, of Clinton; John J. Flaherty, of Gloucester, and Geo. F. Swain, of Boston, appointed to act in the South End grade crossing, after a hearing at the Court House, decided that public necessity and convenience required the abolition of the grade crossing at the South End Bridge.

Hatfield, Mass.—The citizens on Oct. 15 are stated to have voted to expend $3,000 toward a fill and bridge near North Hatfield. This work is to be done in connection with the electric road. The work will cost about $5,000, and the electric road has offered the town $1,600 for its share of the work.

Bath, Me.—Theo. L. Dunn, Ch. Engr., Portland, Me., writes that preliminary examinations are being made for the bridge which the Maine Central R. R. contemplates building across the Kennebec River at Bath.

Lawrence, Mass.—It is stated that the Boston & Maine R. R. Co. (H. Bissell, Ch. Engr., Boston) will erect a $20,000 bridge over So. Union St. About half of the expense will be borne by the Boston & Maine and the remaining $10,000 will be divided between the Boston & Northern St. Ry., the county and the city.

Syracuse, N. Y.—It is stated that plans are about completed at the City Engrs. office and the contract will soon be let for the construction of a bridge over the Oswego Canal at Butternut St.

Mohawk, N. Y.—A press report states that the Utica & Mohawk Valley Ry. Co. will construct 8 bridges; one of the bridges is estimated to cost $140,000. C. H. Clark, Ch. Engr., Utica.

Pulaski, Pa.—The State Viewers appointed by the Dauphin Co. Court are reported to have recommended the construction of a $20,000 stone bridge of two arches at Pulaski (Harrisburg, C. H.).

Newtown, Pa.—Bids are wanted Nov. 1 for building a bridge on Jefferson Ave. in the Boro. of Newtown. Elmer E. Funk, Clk. of County Comrs., Doylestown.

Wilmerding, Pa.—The Pittsburgh Rys. Co. is stated to have awarded to the McClintic-Marshall Construction Co., of Pittsburg, a contract for the erection of a steel viaduct 1,500 ft. long to span the tracks of the Pennsylvania R. R., and the Turtle Creek & Westinghouse traction tracks at Wilmerding.

Scranton, Pa.—Residents of the 10th Ward have presented a petition to Recorder W. L. Connell, asking that bridges be constructed over Roaring Brook at the end of Ash and Myrtle Sts.

New Castle, Pa.—The New Castle Electric Ry. Co. is reported to have submitted to the Co. Comrs. and City Council a proposition providing for the construction of a viaduct from Moravia St. over all the R. R. tracks and the Shenango River to a point on Mahoning Ave. The cost of the viaduct, with the lands necessary for the approaches, is estimated at $200,000, and it has been suggested that this sum be borne in the following proportions: Steam railroads, $100,000; County of Lawrence, $36,000; city of New Castle, $24,000, and the New Castle Traction Co., $40,000.

Towson, Md.—Residents of the 4th District are stated to have petitioned the Baltimore Co. Comrs. to co-operate with the Carroll Co. Comrs. in building a bridge over the Patapsco at Bensons Ford.

Georgetown, D. C.—At the last session of Congress an appropriation of $65,000 was made for the repair of the Aqueduct bridge across the Potomac at Georgetown. A project submitted by Col. Allen, Corps of Engrs., has been approved by Gen. Gillespie. It provides for the reconstruction of pier No. 5 from the bottom up. A raft has been constructed for taking probings at the site of the pier, and it is expected that contracts for the work will soon be let.

St. Paul, Minn.—The Com. on Sts. of the Bd. of Aldermen is stated to have accepted the plans of City Engr. Rundlett for the steel bridge to be constructed at Arcade St., to cost about $54,000.

Mason City, Ia.—The Chicago, Milwaukee & St. Paul R. R. Co. is stated to have decided to partially change and reconstruct its viaduct at Mason City. D. J. Whittemore, Ch. Engr., Chicago, Ill.

Washington, Ind.—Local press reports state that bids will be received Nov. 10 by the Co. Comrs. for the construction of a bridge over the White River. The plans of Engr. E. C. Faith call for a bridge 420 ft. in length, 26 ft. in width and supported by two concrete abutments, each 21 ft. in length, one on each bank, and two piers in the river; probable cost $15,000.

Racine, Wis.—Ch. Engr. Edw'd C. Carter, of the Chicago-North Western Ry. Co., Chicago, writes that the proposition to construct a double track and new bridge at Racine has been considered but has not been authorized.

Anderson, Ind.—Bids are wanted Oct. 29 by Co. Aud. Otis P. Crim, for the building of approaches to bridge over Fall Creek at Cox's Ford. J. Burr, Comr.

New Castle, Ind.—Bids are wanted Nov. 7 for the construction of 6 small steel bridges. Edwin Hall, Comr. of Henry Co.

Watertown, N. Y.—The Jefferson Co. Bd. of Superv. has taken action providing for the construction of 18 miles of highway under the Higbie-Armstrong law. Total estimated cost, $134,620.

Syracuse, N. Y.—The lowest bids received for the paving of East and West Colvin St. are stated to have been as follows: For asphalt—the Empire Contracting Co., at $1.60 per sq. yd., using Alcatraz, curbing at 55 cts., total, $23,993; for brick—John W. Bustin, Syracuse, at $1.87 per sq. yd., using Syracuse brick, total, $27,487.

Troy, N. Y.—Rensselaer County Supervisors have adopted plans and specifications for the improvement of the following highways: Troy-Sand Lake Road, 1.49 miles, cost $15,200; Wynantskill-West Sand Lake Road, 4 miles, cost $39,400; East Nassau Road, 3.02 miles, cost $18,121; the old northern turnpike, from Hoosick River bridge at Eagle Bridge through Buskirk; also the road from station 118x39 to Buskirk's Bridge, a distance of 2.75 miles, in Hoosick, cost $26,250; Brick Church-Rock Hollow Road, a distance of 3.33 miles, cost $33,800; Boston and Albany turnpike, a distance of 5.41 miles, cost $50,300; the Troy-Poestenkill Road, a distance of 3.6 miles, cost $33,450. One-half of the total expense, which is $216,521, is borne by the State and one-half by the county.

Newton, N. J.—The Bd. of Chosen Freeholders of Sussex Co. has awarded contracts for building three sections of macadam roads as follows: Road from Sussex Borough to Newton, to McKernan & Bergen, of Paterson, for $6,611; road from Stanhope to Newton, to the Augustus Munson Co., of Rockaway, for $7,807; road from Sparta to Newton, to McKernan & Bergen, of Paterson, for $4,406.

La Salle, Ill.—Contracts will soon be let for the following work: 26,424 sq. yds. of brick paving on broken stone foundation; 12,158 lin. ft. of stone curbing, and 10,860 cu. yds. of excavating. Estimated cost, $44,850. E. J. Noonan, City Engr.

Burlington, Ia.—The following are the lowest bids opened Oct. 6 for brick paving: Main St.—Geo. Kriechbaum, at $1.35 per sq. yd for paving, 55 cts. per lin. ft. for curbing and 40 cts. per cu. yd. for grading; Valley St.—Geo. Kreichbaum, at $1.80 per sq. yd. for paving, 75 cts. per lin. ft. for curbing, and 45 cts. per cu. yd. for grading.

Pekin, Ill.—The City Council has passed an ordinance providing for the paving of S. 4th St.; estimated cost, $18,096.

Milwaukee, Wis.—The contract for paving Market St., 4,265 yds., has been awarded to the Western Paving & Supply Co. at $2.30 per yd. for asphalt pavement.

Ft. Dodge, Ia.—The City Council has been petitioned to pave several streets with asphalt.

St. Paul, Minn.—City Engr. Rundlett estimates the cost of paving Exchange St., from Cedar to 9th Sts., as follows: Asphalt, $12,308; sandstone, $13,602, and brick, $10,238.

Sebring, O.—The contract for about 5,800 sq. yds. of brick paving is reported to have been awarded to John Hadley, of Canton, for $8,300.

Minneapolis, Minn.—The Park Bd. has decided to expend $7,000 on the new boulevard along the west bank of the river.

Hammond, Ind.—Bids are wanted Nov. 4 for improving sundry streets. W. F. Bridge, City Engr.

Indianapolis, Ind.—Bids are wanted Oct. 29 for improving portions of Cora St. by grading and paving with brick. Harold C. Megrew, Clk. of the Bd. of Pub. Improv.

Delphi, Ind.—Bids are wanted by Co. Aud. Jas. C. Smock, Dec. 1, for grading, graveling, draining, etc., the Burlington and Cutler gravel road; total length about 32 miles. E. E. Kirkpatrick, Engr. in Charge.

Akron, O.—Bids are wanted Nov. 15 for grading, curbing with stone, guttering and paving with brick, on W. Market St. Chas. H. Isbell, City Clk.

Cincinnati, O.—Street paving and improvement bonds to the amount of $200,000 are reported to have been sold.

Topeka, Kan.—The contract for macadamizing W. 6th St. road has been awarded by the Co. Comrs. to Ramsey & Ramsey at 38¾ cts. per sq. yd.

Nashville, Tenn.—The City Council has passed a bill appropriating $28,000 for paving Broad St. and West End Ave., to be available as soon as the property owners raise an additional $6,000 to help pay for the work; bituminous macadam will be used.

Memphis, Tenn.—Local press reports state that the Memphis St. Ry. Co. has arranged for paving within its tracks and 2 ft. on each side of tracks on such streets of Memphis as the tracks are on, and which will be paved by the city, with asphalt. Estimated cost to company is given as $150,000.

Paducah, Ky.—City Clk. W. H. Patterson writes that the proposition to issue $100,000 bonds for street improvements will be voted upon at the Nov. election.

Guthrie, Okla. Ter.—The City Council is said to be receiving bids for paving. Address Mayor Ball.

Boise, Idaho.—Bids are wanted Oct. 30 for the construction of cement sidewalks in numerous streets. Dean Perkins, City Clk.

Toronto, Ont.—An additional appropriation of $20,000 has been made for the improvement of Temiskaming Dist. roads.

Montreal, Que.—The Road Com. has instructed the City Surveyor to ascertain the cost of an asphalting plant to be owned by the city.

POWER PLANTS, GAS AND ELECTRICITY.

Augusta, Me.—The Union River Light & Power Co. has been incorporated to develop the water power of the Union River and its tributaries. A. Wendal Jackson, Pres., N. Y. City, N. Y.; I. L. Halman, Treas., Boston, Mass.

Madison, Me.—A committee is reported to have been appointed to investigate the cost, etc., of installing a lighting plant.

Brooklyn, N. Y.—Plans have been filed for a 1-story brick, heat and light plant, 55x128 ft., to be erected for the city at Clarkson St. and Albany Ave., to cost $30,000. Architect, L. H. Voss, 65 De Kalb Ave.

Patchogue, L. I., N. Y.—The Village Trus. are stated to have granted Irvy Myers, of North Paterson, N. J., a franchise for a gas plant.

Saugerties, N. Y.—The Saugerties Light, Heat & Power Co., of Saugerties, has been incorporated; capital, $50,000. Directors: H. R. Hord and R. C. McCormick, New York.

Addison, N. Y.—The Village Trus. are stated to have granted Jas. R. Reynolds a franchise to pipe gas from the Potter County gas fields to Addison, for fuel and lighting purposes.

McKeesport, Pa.—The Common and Select Council have passed a resolution authorizing the City Controller to secure bids for furnishing the city with electric light after Dec. 15 for 1 year. The ordinance for the municipal electric light plant is reported to have been defeated.

Centralia, Pa.—The Schuylkill Light, Heat & Power Co., of Girardville, is stated to have secured the contract for lighting the city by electricity at $95 per light per year.

Bath, Pa.—A charter has been granted to the Bath Light, Heat & Power Co., with a capital of $1,000, to supply light, heat and power to Bath and adjacent territory. Incorporators: Chas. Shuman and Wilson H. Seem, of Bath; W. M. Bennett, of Nazareth, and others.

Philadelphia, Pa.—Press reports state that plans for the new heat and light plant of the Univ. of Pennsylvania were posted Oct. 17 in the mechanical building by Prof. Spangler. The building will cost about $500,000.

Bradford, Pa.—The Bradford Gas Co. was formed Oct. 18 at the office of L. Emery, Jr., to drill for and produce natural gas to be sold to manufacturers.

Winnsboro, S. C.—Bids are wanted Oct. 29 for erecting an electric lighting plant of 35 arc and 600 incandescent lamps. W. B. Smith Whaley & Co., Engrs., Columbia.

Akron, O.—Bids are wanted Nov. 6 for making all connections, erecting, maintaining and furnishing all material necessary for furnishing the city with good and satisfactory lights for a term of 5 years: the contract calls for 800 or more gas lamps of 50 c. p. each, to be lighted on the moonlight schedule. Chas. H. Isbell, City Clk.

Sycamore, Ill.—City Clk. J. D. Beckler writes that on Oct. 17, at a special meeting of the Council, it was voted to award the contract for city lighting to De Kalb-Sycamore Electric Co.

Bettsville, O.—W. L. Day is stated to have petitioned the Council for a franchise for an electric light plant.

Milwaukee, Wis.—A plan to extend and enlarge the steam-heating service of the Milwaukee Electric Ry. & Light Co. is reported to be under consideration by Pres. John I. Beggs; the plans include the boring of large tunnels through the downtown streets within a few blocks of the plant on Broadway.

Baraboo, Wis.—Local press reports state that the Baraboo Gas & Electric Light Co.'s plant has been sold to Brown & Mayer, of Chicago, Ill. New mains will be laid and the entire system, both for fuel purposes and street lighting, will be put in new. B. H. Strong will be retained as mgr.

Forest, O.—See "Water."

Superior, Wis.—Bids will be received by the Common Council Nov. 18 for a franchise for the construction, maintenance and operation of a plant for the distribution of electric currents throughout the city, supplying said city with electricity for power, heat and lighting purposes. John A. Hobe, City Clk.

Youngstown, O.—A press report states that Chas. Hauk, of Toledo, is about to organize a company to furnish manufactured fuel gas to Youngstown, Warren, Niles, Girard, Struthers and Lowellville.

Worthington, O.—See "Water."

Berwyn, Ill.—The Village Trus. are reported to be investigating the advisability of installing a lighting plant in connection with the water works.

Effingham, Kan.—John W. Wilson, Pres. of the company recently granted a 20-year light franchise, writes that bids are wanted until Nov. 1 for the construction of an electric light plant, to cost about $6,000.

Scranton, Miss.—See "Water."

Talladega, Ala.—Engrs. Collier and Brown, of Atlanta, Ga., are reported to have a representative in Talladega who is preparing plans for the Talladega Co. which proposes developing the water power on a stream 10 miles from the city to generate electric light and power. They have secured all rights and franchises, and will commence active construction at an early date.

Huntsville, Ala.—Mr. Jackson, of Nashville, Tenn., is reported to have been selected to prepare plans for municipal electric light for Huntsville.

Schulenburg, Tex.—Negotiations are reported to be pending for the re-establishment of the electric light plant destroyed by fire last Nov. Alderman L. E. Miller, of Houston, owns the franchise.

Corona, Cal.—F. A. Worthley, Supt. of the Riverside Electric Light Plant, is reported to have been employed by the City Council to furnish an estimate of the cost of an electric light plant for Corona.

San Francisco, Cal.—The Golden State Power Co. is reported incorporated, with a capital of $10,000,000, to develop the water power in Feather River. Directors: C. L. Morrill, Theo. Getty and others.

Ellendale, N. D.—J. A. Johnson, of Fargo, is reported to have petitioned for a franchise for an electric light plant.

Douglas, Wyo.—John Morton and T. J. Williams are stated to have petitioned the Council for a franchise for an electric light plant.

Ballard, Wash.—An ordinance is stated to have been introduced in Council granting Oren C. Wilson and his associates a franchise to install and operate a plant for general electric light and power.

Denver, Colo.—Hendrie & Bolthoff are stated to have secured the contract for installing the electric light plant in the court house, for $3,675.

San Pedro, Cal.—City Clk. O. C. Abbott writes that a 50-year gas plant franchise has been sold to H. C. Rogers, of Pasadena, Cal.

Toronto Junction, Ont.—The Canadian General Electric Co. is stated to have secured the contract for furnishing 85 arc lights with two 50-light transformers, switchboard, etc., for $3,580.

ELECTRIC RAILWAYS.

Bourne, Mass.—The Selectmen are stated to have granted the Middleboro, Wareham & Buzzards Bay St. Ry. Co. a franchise to extend its line to Sandwich. Chas. H. Cox, Ch. Engr., Middleboro.

Waltham, Mass.—The Boston Suburban Ry. Co. is stated to have purchased a site in Waltham and will erect there a central power house to be used as a feeder for its railway system. A general repair shop will also be erected on the site. N. C. Smith, Supt., Newtonville.

Norton, Mass.—The Norton & Taunton Ry. Co. is stated to have petitioned the Selectmen for a franchise for a location from Norton Center to the Easton line. C. E. Short, Ch. Engr., Norton.

College Point, L. I., N. Y.—The Cross Country R. R. Co., of Brooklyn, has been incorporated, with a capital of $250,000, to operate a 15-mile electric surface railroad with termini at College Point and Willets Point. Directors: J. F. McClean, A. A. Halsey and Theo. Bernard, all of Brooklyn.

Dunkirk, N. Y.—It is stated that the Dunkirk & Point Gratiot St. Ry. (D. F. Toomey, Mgr., Dunkirk) is to be extended to Buffalo. A reorganization of the company is now under way and the new road will be known as the Buffalo, Dunkirk & Western Ry. Co.

Huntington, L. I., N. Y.—J. H. Smith, of Brooklyn, with a residence at Farmingdale, is reported interested in the construction of an electric railway between Huntington and Amityville.

Dillsburg, Pa.—A charter has been filed for the extension of the Dillsburg, Wellsville & Dover St. Ry. from Rossville to Lewisberry. Newberry, Goldsboro, York Haven, Dillsburg and Bowmansdale.

Le Roy, N. Y.—The Highway Comrs. are stated to have granted a franchise to the Buffalo & Depew Electric Ry. Co. E. Melvin, Ch. Engr., Depew.

New Castle, Pa.—The New Castle Electric Ry. Co. is stated to have petitioned the Council for franchises for a new extension to be built at a cost of about $50,000. The West Washington St. branch will be extended to the city line, as will also the Pittsburg St. branch.

New Kensington, Pa.—The Council is stated to have granted a franchise to the Tarentum & New Kensington St. Ry. Co.

Philadelphia, Pa.—The Bureau of Surveys has approved plans of the Rapid Transit Co. for the extension of its 19th and 20th Sts. line from Tasker St. to Passyunk Ave., through Lebanon Cemetery. W. S. Twining, Ch. Engr., Philadelphia.

Oswego, N. Y.—It is stated that the Syracuse Rapid Transit Co. has under consideration the extension of its line from Liverpool to Oswego. E. G. Connette, Gen. Mgr., Syracuse.

Bradford, Pa.—C. E. Hudson, Supt. Bradford St. Ry. Co. is reported interested in the construction of an electric railway from Bradford to Jamestown, a distance of about 38 miles.

Brockport, N. Y.—The Brockport, Niagara & Rochester Ry. Co. has been incorporated, with a capital of $500,000, to construct an electric road from Rochester to Medina, a distance of 44 miles. Directors: Fred. Beck, Brockport; W. S. Shields, Waterville, and S. J. Spencer, Buffalo.

Springfield, O.—The Co. Comrs. are stated to have granted the Dayton & Kenton Interurban Ry. Co. a franchise to cross the pikes in Clark County for its line from New Carlisle to this city. R. E. Kline, Ch. Engr., Dayton.

Norwood, O.—The Norwood, Oakley, Madisonville & Red Bank Traction Co. is stated to have secured a right of way over the Red Bank and Brotherton Roads. David Davis, of Norwood, and Peter Eichels, of Red Bank, are among the incorporators of this railway.

Davenport, Ia.—The Scott County Bd. of Superv. are stated to have granted a franchise to the Iowa-Illinois Interurban Ry. Co. to build a line from the city limits of Davenport to a mile beyond Bettendorf on the River Road.

Toledo, O.—W. F. Brown, 864 Oakwood Ave., is stated to have been employed to conduct the final survey for the construction of an electric railway for the People's Rapid Transit Electric Ry. Co. to connect Toledo, Napoleon, Defiance, Greenville, Dayton and other small towns.

Belleville, Ill.—The Belleville Interurban Electric R. R. Co. has been incorporated, with a capital of $5,000, by Henry A. Kirchner, Chas. Becker and others, to construct an electric line in Belleville with branch roads to neighboring towns.

La Salle, Ill.—The Ill. Valley Traction Co. (L. W. Johnson, of La Salle, Supt.) is surveying for an electric line between La Salle and Ottawa; distance, 15 miles.

Kenosha, Wis.—Volney W. Foster, of Chicago, Ill., is reported interested in the construction of an electric railway from Kenosha to Waukegan.

Chattanooga, Tenn.—The Chattanooga Electric Ry. Co. is stated to have decided to extend its line to Chickamauga Park. J. W. McFarland, Supt. and Ch. Electrician, Chattanooga.

Knoxville, Tenn.—The Knoxville Traction Co. has been granted right of way by the County Court to extend a line along the Clinton pike about 1½ miles and on Sharps Gap pike about 1 mile; work will begin within 60 days. C. H. Harvey, Knoxville, Gen. Mgr.

Columbia, Tenn.—The Council is stated to have granted a franchise to the Nashville & Columbia Electric Ry. Co.

Nashville, Tenn.—Percy Warner and E. C. Lewis, of Nashville, Receivers, and R. Lancaster Williams, of Richmond, representing the owners of the Nashville Ry., are reported to be outlining improvements on the Nashville Ry. which contemplates the extension of nearly all of the old lines, the building of new ones and the elimination of unnecessary curves.

Biloxi, Miss.—A charter is reported to have been granted to the Gulf Shore Electric R. R. Co. to construct an electric line from a point at or near Henderson's Point, on the southeastern shore of the Bay of St. Louis, to Point Cadet, being the eastern shore point in the city of Biloxi; total length of proposed line is 20 miles. Incorporators: W. W. Hungerford, Geo. P. Hewes and others.

McKinney, Tex.—Jesse Shain and I. E. Reeves are reported to be on the committee appointed to secure right of way for the McKinney & Blue Ridge Rapid Transit Ry.

Waco, Tex.—The Union Traction Co., of Cleveland, O., is reported to have made a proposition to a number of towns between Waco and Dallas for an electric road between these two cities, to do both a passenger and freight business.

Paris, Tex.—J. S. Williams, Sterling Price and S. B. M. Long, of Paris, are reported to have met with C. C. Dorchester and Cecil Lyon, of Sherman, here on Oct. 16 for the purpose of discussing the proposed electric railway between Paris and Sherman.

Atoka, Ind. Ter.—The Lehigh Traction Co. is reported incorporated to construct an electric railway from Atoka to Coalgate, a distance of 15 miles. Principal office to be at Atoka.

Marshall, Tex.—Y. D. Harrison, of Marshall, representing a company, is stated to have petitioned the Council for a franchise.

Phoenix, Ariz.—It is reported that the Co. Superv. have granted Weirich & Latham a franchise for the construction of an electric railway from Phoenix to Glendale and to Mesa City, a distance of about 30 miles.

Missoula, Mont.—D. A. Barlow, of Missoula, is stated to have petitioned the City Council for a franchise.

Hillsboro, Ore.—The City Council is stated to have granted a 25-year franchise to the West Side & Suburban Ry. Co. for the construction of an electric motor line through the city. The line is to be built from Portland and will probably extend to Forest Grove.

Oakland, Cal.—The San Francisco, Oakland & San Jose R. R. Co. has petitioned the Council for a franchise for an electric railway, commencing on Yerba Buena at its intersection with the southern line of Emeryville, thence westerly to the western limits of Oakland.

The Oakland Transit Consolidated Ry. Co. has also petitioned the Council for a franchise for the construction of additional lines. F. W. Nelson, Ch. Engr., Oakland.

RAILROADS.

Schenectady, N. Y.—The State R. R. Comn. on Oct. 16 granted the petition of the city of Schenectady for the abolition of R. R. grade crossings; the contemplated improvement will cost about $2,000,000.

Newton, Ia.—The Newton & Northwestern R. R. Co. is reported incorporated, with a capital of $2,500,000, to construct a railroad from Newton to Fraser, Gourie, Rockwell City and Sioux City. Principal office to be at Boone. Hamilton Browne, Pres.; W. A. Kelly, Secy.

Salina, Kan.—A press report states that the Union Pacific Ry. Co. will expend about $100,000 in improvements at Salina, including the erection of roundhouse. J. B. Berry, Ch. Engr., Omaha, Neb.

Bloomfield, Mo.—The St. Louis & Gulf Ry. Co., of St. Louis, is reported to have filed with the Secretary of State resolutions to extend a branch railroad from a point north of Bloomfield to a point on the line of its road in Dunkin County, between Calagoa and Campbell, a distance of 35 miles. G. W. Carlisle, Div. Supt., Bloomfield.

Louisa, Ky.—A press report states that the work of surveying for the Seaboard Air Line is about completed. The line above Louisa extends along the west side of Tug River to Naugatuck, and to the Breaks, by way of Peter's Creek, and across to the waters of John's Creek, following that stream to the most favorable point for getting through to the Levisa fork of the Big Sandy. Three tunnels will be constructed on this line. W. W. Gwathmey, Jr., Ch. Engr., Portsmouth, Va.

Wetmore, Tenn.—A charter has been granted to the Ocoee Valley Ry. Co., with a capital of $10,000, to construct a railroad from Wetmore to Copper Hill. Principal office to be at Knoxville. Incorporators: J. L. Boyd, J. E. Lutz, Al. A. Yeager and others.

Ducktown, Tenn.—A press report states that the Louisville & Nashville R. R. Co. (R. Montford, Ch. Engr., Louisville, Ky.) may completely change the route of the Atlanta, Knoxville & Northern through the mountain near Ducktown. The contemplated change will cost about $2,000,000 and will reduce the length of the road 22 miles, as well as avoid heavy grades and difficult passages. The proposed route is through the Ocoee River cavern.

Natchez, Miss.—The Natchez & Gulf R. R. Co. has been incorporated to construct a railroad from Natchez to Gulfport. Incorporators: J. W. Lambert, W. H. Shields and others.

Blytheville, Ark.—The Chickasawba R. R. Co. has been incorporated, with a capital of $75,000, to construct a railroad from Blytheville east to the river.

Austin, Tex.—The charter of the Trinity & Brazos Valley Ry. Co. has been filed, providing for the construction of a line of railway from a point on the Brazos River in Hood Co., southeast, via Cleburne, Hillsboro, Hubbard and Mexia, to a point on the Sabine River in Orange Co., in all about 300 miles. S. R. Wrightington and S. E. Young, of Boston, Mass.; E. M. House and R. H. Baker, of Austin, are among the incorporators.

Galena, Mo.—The Galena, Frontenac & Northern R. R. Co. is reported incorporated, with a capital of $100,000, to construct a railroad from Frontenac to Galena. R. B. Billerly and John L. Christopher, of Topeka, are reported to be among the incorporators.

Florence, Ala.—J. L. Bell and associates, of New York, are reported to have secured a right of way through Florence and terminal facilities for the Alabama & Tennessee R. R. The road will run between Florence and Clifton, Tenn., a distance of 65 miles, and will have a branch road 15 miles in length.

Denver, Colo.—The Colorado-Utah Construction Co. is reported to have contracted with the Denver, Northwestern & Pacific Ry. Co. to build and equip about 500 miles of its railroad, between Denver and Salt Lake City, Utah. This contract provides for a substantial roadbed, 80-lb. steel rails and modern passenger and freight equipment.

Dunbar & Sullivan, Buffalo	12.00	2.00	12.00	21,832
J. J. Fitzpatrick, Plattsburg, N. Y.	11.87	1.59	11.87	20,702
H. H. Sturgis, S. Standish, Me.	9.37	2.10	10.37	19,385

*Contract awarded. The contract for removing 1,500 cu. yds. of rock at Saugerties Harbor (bids opened Oct. 20) has been awarded to R. G. Packard Co., New York City, at $5.30 per cu. yd.

Philadelphia, Pa.—Bids will be received at the Bureau of Supplies and Accounts, Navy Dept., Washington, D. C., Nov. 4, to furnish the Navy Yard, League Island, Pa., with a quantity of cement; also for erecting a storehouse at Naval Magazine, Ft. Mifflin, Pa. A. S. Kenny, Paymaster Gen., U. S. Navy.

Washington, D. C.—Bids will be received Nov. 18 at the Bureau of Supplies and Accounts for furnishing at the Navy Yard, Puget Sound, Wash., a quantity of railroad material, electrical supplies, etc., and for the erection and installation of electric generating and distributing plant. A. S. Kenny, Paymaster Gen., U. S. Navy.

Charleston, S. C.—The Navy Department, Washington, has awarded a contract for building the first granite and concrete dry dock at Charleston Navy Yard to the New York Continental Jewell Filtration Co., at about $916,000.

Savannah, Ga.—The lowest bid received Sept. 27 by Capt. Cassius E. Gillette, Corps of Engrs., U. S. A., for repairing and adding to Mackay's Point training wall, Savannah Harbor, was from D. Power & Co., Savannah, as follows: Piling (common), 5,400 lin. ft., at 5 cts.; piling (cluster), 330 lin. ft., at 7 cts.; pile-driving, 2,700 lin. ft., at 9 cts.; mercht. timber, 12,000 ft. B. M., at $30; brush in bundles, 2,000 cu. yds., 51 cts.; stone, 1,800 cu. yds., $2.25; iron, 2,000 lbs., 4 cts.; total, $6,046. Other bids were from Egan Smith & Co., of Jacksonville, at $9,795, and Sam. W. Skinner, Wilmington, N. C., at $9,889.

Muskegon, Mich.—The lowest bid opened Oct. 15 at the U. S. Engineer Office, Grand Rapids, for constructing revetment and repair of pier at Muskegon was from Robert Love, of Muskegon, at $52,317.

Jeffersonville, Ind.—Bids are wanted Oct. 30 at the Depot Q. M. Dept. for supplies, including circulating boilers, sheet zinc, etc. J. M. Marshall, Asst. Q. M. Gen.

Fergus Falls, Minn.—The contract for the constructing of the U. S. Government Bldg. in this city is stated to have been awarded to Lauritzen Bros., of Fergus Falls, for $80,073.

Ft. Morgan, Ala.—Bids are wanted at the U. S. Engineer Office, Mobile, until Nov. 22 for raising and strengthening sea wall at Ft. Morgan, as advertised in The Engineering Record.

St. Louis, Mo.—The contract for the structural steel work for the Government Bldg. at the Louisiana Purchase Expo. is stated to have been awarded to the Penn Bridge Co., of Beaver Falls, for $102,570.

Nashville, Tenn.—Bids are wanted Nov. 24 for building dredge. Lieut. Col. M. B. Adams, Corps Engrs., U. S. A.

Boise, Idaho.—Bids are wanted at the Treasury Dept., Washington, D. C., until Nov. 25 for the installation of a conduit and electric wiring system for the U. S. Public Bldg. at Boise; bids are also wanted Nov. 29 for steam heating and ventilating apparatus for said building, as advertised in The Engineering Record.

Aberdeen, S. D.—The contract for constructing the U. S. Post Office Bldg. is stated to have been awarded to E. Miller & Co., Aberdeen, for $136,400.

MISCELLANEOUS.

Hartford, Conn.—The Bd. of St. Comrs. will receive bids Oct. 29 for 600 ft. of concrete culvert, 10 ft. in diameter, with necessary excavation, partly in rock.

New York, N. Y.—The following bids were opened Oct. 17 at the Dept. of Docks and Ferries for (*a*) rebuilding and extending W. 58th St. pier and (*b*) dredging thereat: Degnon-McLean Const. Co.: *a*, $83,426; *b*, 22 cts. Bernard Rolf, 39 Cortlandt St. (awarded): *a*, $73,333; *b*, 16 cts. H. L. Spearon: *a*, $75,608; *b*, 14 cts. Augustin Walsh: *a*, $83,000; *b*, 20 cts. Wm. H. Jenks: *a*, $78,442; *b*, 14 cts.

Bids opened at the same time for dredging on the North River, between the Battery and 159th St., were as follows: Henry DuBois Sons' Co., 17 State St. (awarded), 14 9/10 c. per cu. yd.; Wm. H. Beard, 18c.; W. H. Taylor, 15¾c.

Watervliet, N. Y.—Bids are wanted Oct. 29 for cleaning out culverts in Dry River, and repairing wing wall at 18th St. culvert. Luhr Eggles, City Clk.

New York, N. Y.—Bids will be received Nov. 3 by McDougall Hawkes, Comr. of Docks, for dredging in the North River between W. 21st and 23d Sts.

Brooklyn, N. Y.—J. M. Briggs was the lowest bidder Oct. 23 for building shore protection at the end of Ocean Parkway at Coney Isl. Concourse, his bid being $15,590.

Syracuse, N. Y.—Bids are wanted Nov. 1 for $50,000 Onondaga Creek improvement bonds; also on same date for $10,000 Harbor Brook improvement bonds. E. J. Mack, Compt.

Baltimore, Md.—Local press reports state that the Baltimore & Ohio R. R. Co. has invited bids for the steamship pier to be erected at Locust Point, at this port. This improvement will represent an outlay of about $500,000; length of pier to be over 500 ft., with two decks.

Milwaukee, Wis.—Local press reports state that the dry docks of the Milwaukee Dry Dock Co. (J. C. Wallace, Gen. Mgr.), at the foot of Mineral St. and on Vogel's Island, are soon to be enlarged at an estimated cost of $100,000.

New Orleans, La.—T. J. Duggan, Secy. Orleans Levee Dist., writes that the contract for reconstructing the levee from Clouet to Pauline Sts., 3d Dist. of this city, has been awarded to W. T. Carey & Bro., of New Orleans, for $23,496.

NEW INDUSTRIAL PLANTS.

The Compensating Pipe Organ Co., Ltd., Battle Creek, Mich., is being organized, and will erect a 300x60-ft. main building, with smaller buildings for engine, boilers, packing and dry kilns. A 150-H.-P. engine, two 100-H.-P. boilers and wood-working machinery will be installed.

The Mitchell Wheel Co., Miamisburg, O., will erect a 300x70-ft. main building, with dry-houses, warehouses, etc. Engine and boilers of 200 H.-P. will be installed.

The Graham Foundry & Machine Co., Monongahela, Pa., will be reorganized and incorporated, and a new plant will be erected. The company will require considerable new equipment, and desires catalogues and price lists from manufacturers.

The Kalispell (Mont.) Malting & Brewing Co. is planning to double the capacity of its plant and install an ice machine.

R. S. Fram, Vandalia, Ill., is interested in the erection of a paper mill, which will include buildings of the following sizes: 25x100, 40x50, 20x35, 35 ft. square, and 30 ft. square. Four 16-ft. boilers of 60-in. diameter, having a capacity of 320 H.-P., a 200-H.-P. Corliss engine and a 25-H.-P. slide valve engine will be installed.

The Miller-Lewis Co., Columbus, O., manufacturing stationers, are erecting a 2-story brick factory, to be equipped with elevator, electric lighting and individual direct-current motors at 220 volts for the machines.

The Geneva (N. Y.) Woven Label Works is erecting 56x90 and 24x30-ft. buildings. Electric power of about 30 H.-P., purchased from a local company, will be required.

The White Enamel Refrigerator Co., St. Paul, Minn., has purchased a brick building about 191x267 ft. in size at Midway, which it is remodeling, and the company is also erecting a 64x200-ft. warehouse. The factory will be supplied with electric power and light and steam heat.

The Camden (S. C.) Water, Light & Ice Co. will rebuild its ice plant, and is in the market for a 15-ton plant.

The Pacific Coast Pipe Co., Spokane, Wash., will erect a 100x200-ft. building to replace plant recently burned. The new plant will have a daily capacity of 3,000 to 5,000 ft. of pipe, and will be enlarged by a brick addition in the spring.

The Southern Steel & Smelting Co., 2 N. Paca St., Baltimore Md., contemplates erecting a smelting plant in the near future.

The Barnard & Leas Mfg. Co., Moline, Ill., maker of mill and elevator machinery, expects to erect a new foundry soon, but details are undecided.

The Seaboard Steel Casting Co., Chester, Pa., will increase the capacity of its plant about one-third, adding a steel building, connected to the main foundry, for storing flasks, and equipped with a traveling crane; a large drying oven; 25-ton furnace; about 50 ft. to the machine shop, and install additional tools to increase the finishing department. Another traveling crane will be installed in the machine shop.

M. Gould's Son & Co., 61-63 Hamilton St., Newark, N. J., makers of trunk hardware and brass goods, are erecting a 4-story, 50x120-ft. building and expect to install a 25-H.-P. gas engine, a 200-light dynamo, three or four drop presses, three or four cutting power presses and exhaust tumbling barrels.

BUSINESS NOTES.

The York (Pa.) Mfg. Co. reports receiving the following orders: Frank Banard, Castries, W. I., 5-ton ice plant; People's Pure Ice Co., Chicago, 65-ton refrigerating plant; Marlin (Tex.) Ice & Cold Storage Co., 30-ton ice plant; Pelican Ice Co., New Orleans, La., 75-ton ice plant; Miller Brewing Co., Rochester, N. Y., 100-ton refrigerating machine; Retail Grocers' Ice Co., Little Rock, Ark., 50-ton ice plant; Gardeners' & Shippers' Ice Co., New Orleans, 25-ton ice plant; Mt. Vernon (Ohio) Ice, Coal & Milling Co., 25-ton ice plant; Border City Ice & Coal Co., 50-ton ice plant; Liberty Brewing Co., Springfield, Mass., two 65-ton refrigerating machines; J. T. Jones, Gulfport, Miss., 15-ton ice plant; Butler (Pa.) Ice Co.; S. Castleman, Belzona, Miss., 15-ton ice plant; People's Ice & Fuel Co., Charlotte, N. C., 30-ton freezing and distilling plant; J. Frederick Weissner, 10-ton freezing system; Belle Springs Creamery Co., Abilene, Kan., 40-ton refrigerating machine and 12-ton freezing and distilling system; Durban (South Africa) Breweries & Distilleries Co., 12-ton freezing outfit.

The Ball Engine Co., Erie, Pa., reports the recent receipt of the following orders: Engines for the electric plant of the Temple Court Bldg., Denver, Colo.; two engines for the John Deere Plow Co., Kansas City, Mo.; an engine for an electric plant at Wilburton, Ind. T.

N. A. Christensen, Herman Bldg., Milwaukee, Wis., has now control of the manufacture of his air compressors, except those connected with air brakes exclusively, which will be manufactured by the Christensen Engineering Co., of which he was formerly superintendent and is still consulting engineer.

The Columbian Cordage Co., Auburn, N. Y., has recently contracted with Westinghouse, Church, Kerr & Co. for a generating equipment, comprising water-tube boilers, Roney stokers, economizers, mechanical draft, coal-handling apparatus and high-pressure steam piping. The present boiler plant contains five water-tube boilers, hand fired, operating at 100 lbs. pressure. The new plant will contain 1,575-H.-P. boiler capacity, and the transformation will take place without disturbing the operation of the plant. The present brick chimney will be retained and used in connection with the mechanical draft apparatus, as it is necessary to provide means to elevate to a suitable height the waste acid gases resulting from the various chemical processes of rope manufacture.

The Electrical Equipment Co., 939 Monadnock Bldg., Chicago, has been awarded a contract for the installation of a lighting plant for the City of Washington, Ia. The equipment includes a Westinghouse three-phase 60-cycle generator, direct-connected to an Ideal engine. Work is now under way, and the plant will be in operation about Jan. 1. The same company has also been awarded a contract for the installation of a water-power electric transmission plant for the Rouge River Light & Power Co. at Rockford, Mich. The equipment includes two General Electric generators and various motors ranging in size from 10 to 50 H.-P. The plant will be in operation Dec. 1, 1902.

The Keystone Coal & Coke Co., Greensburg, Pa., has contracted with Wm. B. Scaife & Sons Co., Pittsburg, for a large filtering plant for their waterworks at Madison, Pa. Among other recent contracts taken for the Scaife and We-Fu-Go water-filtering systems are the following: W. D. Boyce Paper Co., Marseilles, Ill., 1,000,000 gals.; Thomas Phillips Co., Akron, O., 750,000 gals.; Carroll Hotel, Vicksburg, Miss., complete filtering system.

The Philadelphia Pneumatic Tool Co. states that the sales for September have amounted to 20 per cent. more than any previous month. During the current month the monthly record for foreign shipments has already been broken, large orders having been received from Great Britain, Germany, France, Italy and Denmark.

The Stanley Electric Mfg. Co. has recently opened a sales office in the Empire Bldg., Atlanta, Ga., to take care of the increasing demand for apparatus in the South. The office is in charge of George P. Hardy.

The Dixon Garbage Crematory Co., Toledo, O., has just completed the construction of a new garbage crematory plant for the Quartermaster's Department of the U. S. Army at the San Juan Post.

The New England Structural Co., Boston, is building foot-bridges for the Pemberton Mills, Lawrence; Forbes Lithograph Mfg. Co., Revere; and the Ipswich Mills Co.

The F. D. Cummer & Son Co., Cleveland, has just closed a contract with the Midland Portland Cement Co., Indianapolis, Ind., for three dryers; one for coal, one for stone, and one for clay.

The Goodall Worsted Co., Sanford, Me., is building a large addition to its present works, and has purchased from the Westinghouse Electric & Mfg. Co., a 400-Kw., two-phase, alternating-current generator which will be belted to an 800-H.-P. Brown engine. The generator will furnish power to all departments of the plant by means of Westinghouse induction motors, and will also provide current through transformers for lighting at 104 volts.

THE ENGINEERING RECORD.

Volume XLVI., Number 18.

TABLE OF LEADING ARTICLES.

Some Peculiarities of Industries.......... 409
The Power Plant of the Cambridge Electric Light Company, Cambridge, Mass. (Illustrated)..... 410
The Hydraulic Power Plant of the Riverside Power Company.......... 412
Electrical Apparatus in English Coal Mines. (Illustrated).......... 413
Cooper's Bridge Foundation Specifications. (Illustrated).......... 414
The Use of Slag in Cement Making.......... 416
A Protracted Job of Underpinning. (Illustrated) 417
The Erection of the Pennsylvania Railroad Train Shed, Pittsburg. (Illustrated).......... 419
Fire and Load Tests of Concrete-Steel Floors. (Illustrated).......... 421
Water-Supply Systems in the Ansonia Apartment Hotel. (Illustrated).......... 422
A Seaside Resort Steel Pier and Pavilion. (Illustrated).......... 424

The Engineering Record, conducted by Henry C. Meyer, is published every Saturday at 21 Park Row, New York. Its opinions on technical subjects are either prepared or revised by specialists.

Subscriptions are received and single copies supplied by the International News Company, Breams Building, Chancery Lane, London.

The subscription rate is $5 a year for the United States, Canada and Mexico, and $6 for other countries in the Postal Union. Remittances should be made by check, New York draft or money order in favor of The Engineering Record. No responsibility is assumed for payments made otherwise, except those for subscriptions to the International News Company.

Some Peculiarities of Industries.

In the investigations of the census bureau a good many curious facts are brought to light which would otherwise be buried in local histories. Some of these facts relating to the localization of industries have been compiled by Dr. Frederick S. Hall, and some of his statements are full of interest as showing how other causes than the presence of cheap raw materials or good shipping facilities have caused certain trades to become localized in small cities or country districts. These two factors have been potent in many cases, of course, and even Chicago enterprise could not take from Baltimore its precedence in oyster canning nor could Yankee thrift compete in coke making with the Connellsville district. But in some lines of manufacture, the history is simply a record of the result of a mere chance.

A good instance of the result of chance is afforded by Lynn's position in the shoe trade. It is the result of one Adams Dagyr's choice of that place as a home in 1750. He was a skilled Welsh shoemaker who trained his apprentices so well than in 1764 he was termed "the celebrated shoemaker of Essex." His influence was all-important in causing the manufacturing spirit of his town to lean toward his specialty, and it is not surprising, therefore, that in a calling where skilled labor was the most important element of manufacture until a comparatively few years ago, Lynn occupies a prominent place. Over 40 per cent. of the products of the city, on the basis of value, are boots and shoes, the proportion being exceeded only in Brockton, with 75 per cent., and Haverhill, with 61 per cent.

The inventive genius of a woman is responsible for the most localized industry in the country, and the fact that this woman was the wife of a blacksmith of Troy has given that town the distinction of being the first city of the country in the collar and cuff industry. We can imagine the value of detachable collars and cuffs would appeal strongly to the wife of the village smith. but it is a little surprising to learn that the great business behind such an idea was first scented by a Methodist minister, who established the first collar and cuff shop in the town about three-quarters of a century ago. Manual skill is necessary in this industry, and the large supply of specially skilled labor in Troy has localized the manufacture in that city, which now produces 85.3 per cent. of the total product of the country.

The glove manufacturing of the country was localized by the barter of a country glove maker. About the middle of the eighteenth century, Sir William Johnson brought many Scotch families to his great estate in New York, and among them were some members of the glove guild of Scotland. They brought the simple implements of their trade with them and taught their children the trade. It never amounted to anything, however, until about 1809, when a quantity of gloves were sent on horseback to Albany. They sold readily and a demand for them soon arose which fixed Gloversville and Johnstown as the centers of the industry. Skilled labor thus became abundant there, and, as this is the decisive element of the industry, English, French and German glove makers establishing branches in this country have settled in those two towns, which now produce over 54 per cent. of all the leather gloves made in the country.

One of the most interesting examples of localization is afforded by the knit-goods industry, in which Philadelphia, Cohoes and Amsterdam are the leading centers. In Philadelphia the first start was made in 1698 when a large number of skilled hand knitters from the German Palatine settled in Germantown. The industry was fixed at Cohoes in 1832 when Egbert Egberts of that place invented the first power knitting machine; the abundant water-power at the town made the use of the machine very profitable. The neighboring town of Amsterdam likewise possessed a valuable water-power, and it was not long before the knitting industry was firmly established there as well. There is a further localization to be mentioned in this connection, moreover, for Philadelphia knitters manufacture hosiery almost exclusively, while underwear and other knit goods are the chief products of Cohoes. An analogous condition is found in the boot-and-shoe industry; Brockton makes men's shoes, Lynn ladies' shoes and Haverhill shoes for young people and children.

The pottery trade centers at Trenton and East Liverpool, a fact that illustrates the prevalence of the law of heredity in manufacturing as well as in natural history. Skilled labor from abroad settled at both these points, where coarse pottery was already made from local deposits of clay. The industry is one in which skilled handwork prevails to an unusual degree, and the advantage of possessing this labor was increased in the case of the two cities mentioned by facilities for water transportation and proximity to coal supplies. The manufacture of porcelain and other fine-grade pottery was undertaken, and the industry so firmly established that these two places remain its centers, although the clay used in Trenton for the purpose is brought more than 50 miles and none of that used for the fine product of East Liverpool is found within hundreds of miles of the city. The demand for sanitary porcelain in New York and Philadelphia has stimulated its manufacture at Trenton, while many of the East Liverpool makers specialize in fine chinaware.

Localization of this nature is peculiar neither to the present time nor this country. An English book of the thirteenth century tells of the localization of scarlet cloth in Lincoln, burnet at Beverly, russet at Colchester, needles at Wilton and razors at Leicester. In Russia there are now over 500 villages devoted to various branches of woodworking, in one village practically nothing being made except spokes for the wheels of vehicles, in another nothing but the bodies, and so on.

These few instances of specialization and localization of industries from other causes than proximity to raw material, good shipping facilities or abundant water power are particularly interesting because of the probability that another ten years will see changes in the census figures far greater than any yet recorded. Combinations of one sort or another are taking place in so many industries that the managers will soon be in possession of statistics showing definitely where certain classes of goods can be made best. At these places, consequently, there will probably be a specialization or localization beyond anything yet witnessed, while other places will lose industries for which they have long been noted. This will work hardship to many operatives and mechanics who must change their homes or go into other trades, but the result will eventually be beneficial. The manufacture of agricultural machinery, largely in the hands of a few great firms, has become localized on these grounds in places where freight rates and proximity to hardwood timber have shown that the products are turned out and shipped with the least expense. The same thing is taking place quietly but extensively in the iron and steel trade, while its occurrence in the furniture business is so recent and marked as to require no comment. It is full time to recognize that native shrewdness and manufacturing skill have to face now a new competition in the enormously valuable statistics which uniform systems of accounting place at the disposal of the managers of combinations of manufacturing plants of a similar nature.

Construction on the Louisiana Purchase Exposition grounds is making good progress, according to a recent report of Director of Works Taylor. Of the nine buildings which are to form the main group of the fair, seven are in course of erection. The Manufactures Building has recently been contracted for, and the Transportation Building, it is anticipated, will be put under contract very shortly. There are now about 8½ miles of railway and spur tracks on the grounds. In connection with the landscape work 127 large trees, from 9 to 16 inches in diameter, were transplanted, and, with the exception of 8 or 10, all have grown remarkably well.

The Atlanta Water & Electric Power Company has begun the construction of works for the development of nearly 20,000 horse-power at a point on the Chattahoochee River about 16 miles from Atlanta. It is estimated that the plant will cost $1,500,000 and will require about eighteen months for construction. The principal features of the work will be a concrete dam across the river 50 feet high and about 1,100 feet long and a power house of concrete steel construction 200 feet long. The equipment will consist of seven 1,500-kilowatt generators, each direct-connected to a pair of turbines with a maximum capacity of 2,500 horsepower under a head of 50 feet. The electrical machinery is being supplied by the Westinghouse Company. The hydraulic machinery will be furnished and the dam and power house built by the S. Morgan Smith Company, of York, Pa. At the present time about 250 men are employed upon the construction of cofferdams and erection of cableways. There are to be three cableways across the stream to be used in depositing the 60,000 cubic yards of concrete masonry. Mr. S. Morgan Smith, of York, Pa., is president of the company, and Mr. Forest Addair, of Atlanta, is vice-president.

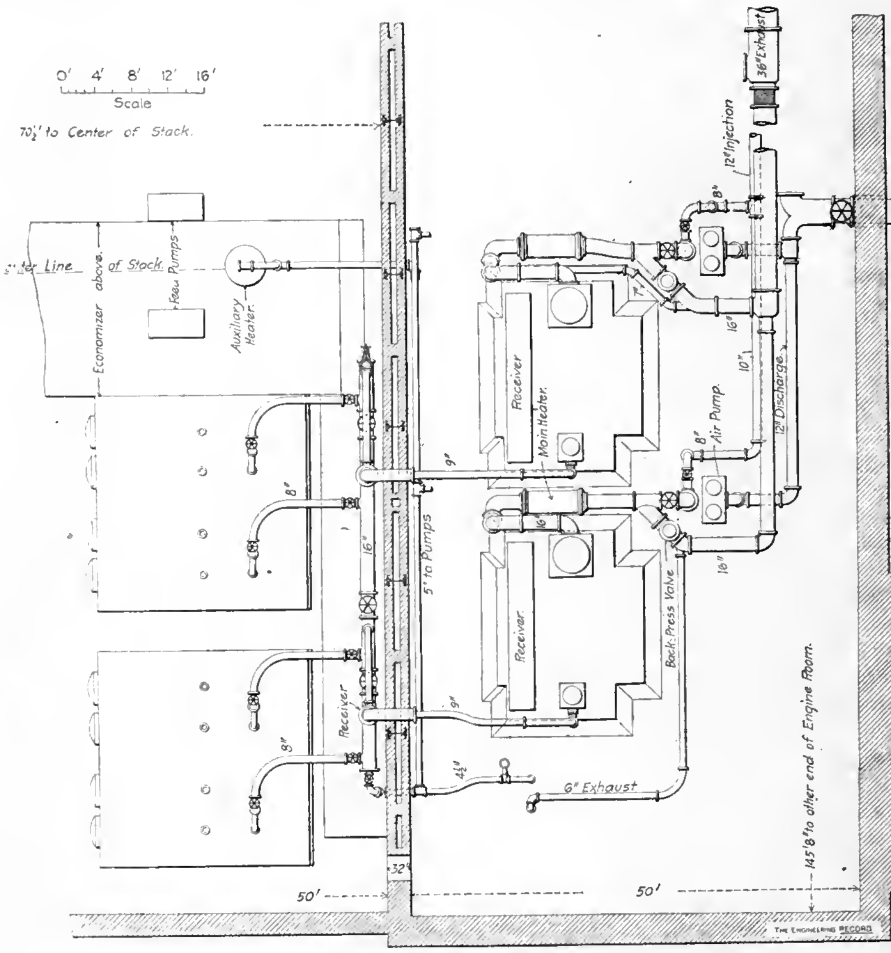
Power Plant of the Cambridge Electric Light Company, Cambridge, Mass.

The Cambridge Electric Light Company has recently completed a distinctly modern electric lighting and power plant, on Western Avenue near the Charles River, in Cambridge, Mass. The new plant is an alternating-current one with a three-phase 60-cycle supply furnished from direct-connected vertical compound condensing generating units, of which the steam engines are to receive superheated steam. In addition to both main and auxiliary feed-water heating, economizers have been provided, to utilize the heat of the flue gases. Among other notable features of the plant may be mentioned the lofty character of the building, which has resulted in well lighted and ventilated boiler and engine rooms, an unusually light basement under the engine room, due to numerous outside windows in that story and to several openings in the engine room floor, the use of a traveling crane in the boiler room as well as in the engine room, and an extensive provision of special pipe hangers to allow for expansion changes in practically all classes of piping. The old plant, near which the new one has been built, had been outgrown by a rapidly increasing business and is to be entirely dismantled.

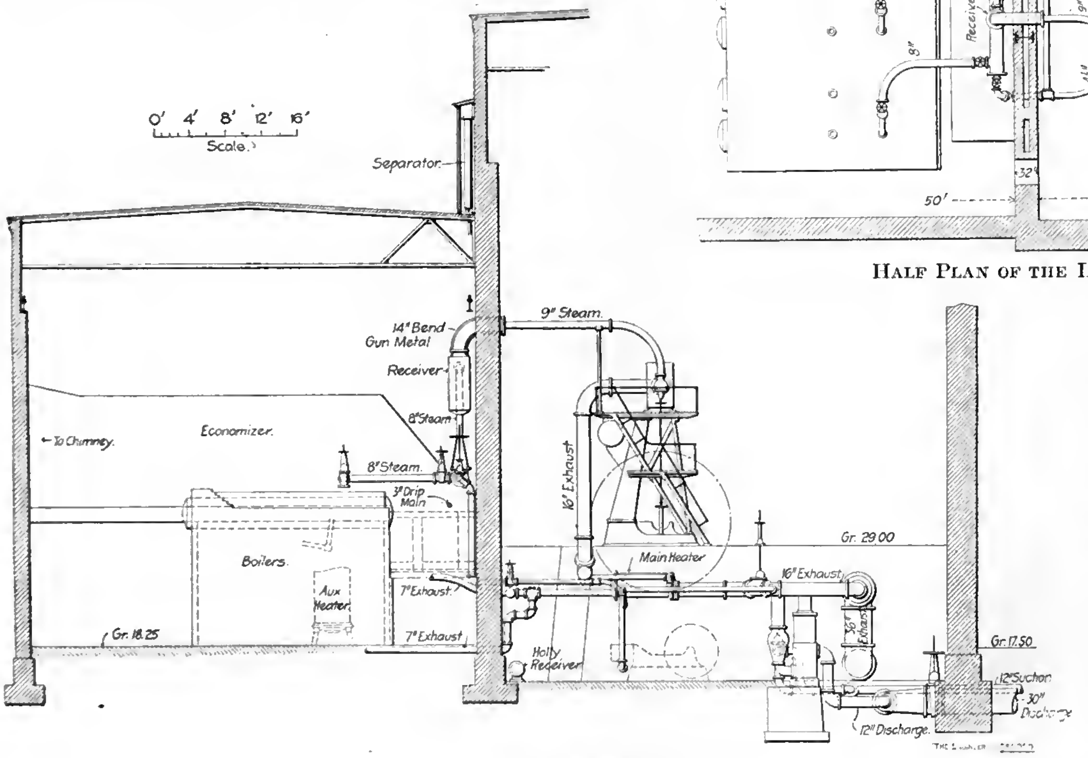
The power house is a steel frame building with brick walls and a timber roof supported by steel trusses. The street walls of the building are built with an enclosed air space of 8 inches, and are faced on the outside with a cut-stone base course and surmounted at the roof by a heavy balustrade. In main dimensions the building is 106 feet x 151 feet 4 inches and is of the class in which the engine and boiler rooms are side by side, the longitudinal partition being composed, similarly to the street walls, of two 12-inch walls with 8 inches air space between. The boiler and engine rooms are of the same width, 50 feet, and are 145 feet 8 inches long, but if desired, one end wall may be torn down and indefinite extension made. The floor of the engine room is 10 feet 9 inches above the level of the boiler room floor, and the basement floor 4 feet 3 inches below it, leaving a clear height in that story of 13 feet 8 inches. In the boiler room, the lower chord of the roof trusses is 41 feet 9 inches above the boiler room floor; in the engine room, the distance is about 52½ feet. In the case of each room, the roof has a large monitor, and in the engine room, in addition, there is a row of windows in the upper part of the main walls above the main windows. The interior walls of the boiler room are of red glazed brick for perhaps the first ten feet, and are painted white above; the under side of the roof is white, while the roof trusses are painted green. The floors are all of cement. The cranes are 25-ton hand-power Maris traveling cranes.

The boiler room contains two batteries of Babcock & Wilcox water-tube boilers, two boilers in each battery. There is space for a future installation of two similar batteries in the present building. Located in the center of the present boiler room are two boiler feed pumps, the auxiliary feed-water heater and the economizer, the latter supported overhead, so that the floor space underneath could be utilized for the pumps and heater. Incidentally the flue gases do not have to be carried downward in their passage from the boilers to the stack, which rises outside of the building as an entirely independent structure.

Each boiler contains 192 4-inch tubes 18 feet long, arranged in 16 sections 12 pipes high, and two 42-inch steam drums 23 feet 3⅝ inches long. They were built to carry 200 pounds pressure, and the steam connections are made so that before entering the steam header all the steam from each boiler must pass through a superheating coil which contains 125 square feet of heating surface. Grates have been provided for burning soft coal, and the grate surface in each boiler is 67.6 square feet, bearing a ratio to the total heating surface of each boiler, which is 3,964.5 square feet, of 1 to 58.7. No provision has yet been made for mechanically handling coal, as it is conveniently brought to the boiler house by water.



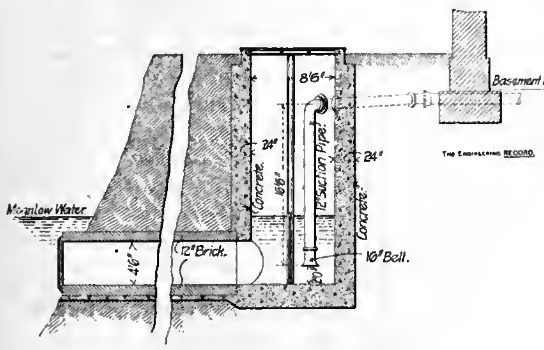
HALF PLAN OF THE LIGHTING STATION.



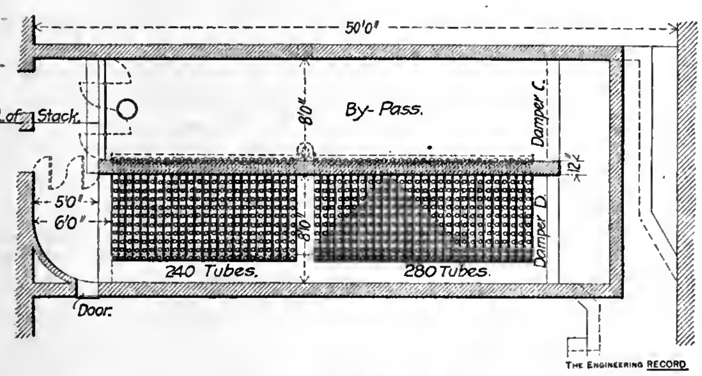
CROSS-SECTION OF THE STATION.

The smoke passage is located immediately behind the boilers and is of brick, its floor and ceiling consisting of arches sprung between light I-beams that extend from the partition wall to the boiler setting. The wall of the passage back of the boilers is 12 inches thick. The floor and the roof above the ceiling arches are both covered level with Portland cement mortar, composed of equal parts of sand and cement, with the mortar 4 inches thick above the I-beams in the floor construction. The inside area of the smoke duct is constant its entire length, 36 square feet, which is not quite 54 per cent. of the aggregate area of the four openings into the smoke passage from the four boilers.

At the center of the boiler room the breeching is carried upward into the economizer setting, which is a brick structure of 12-inch walls, carried on steel columns from the boiler room floor and having brick arch floors and roof finished with Portland cement plaster. The setting is constructed to have a central direct smoke passage to the chimney with two sets of economizer tubes on each side. Half of the full boiler plant only having been installed, the second set of tubes has not been put in place and as now built, the economizer setting comprises one set and the by-pass. The by-pass passage has an area of 60 square feet, which is 1 2/3 times the area of the present smoke passage. The economizer was built by the Green Fuel Economizer Company and consists of the usual 4-inch tubes 9 feet high, arranged in two groups, one of 280 tubes and the other of 240 tubes. An accompanying drawing indicates the method of operating the dampers controlling the entrance to the setting. Each of the two dampers is



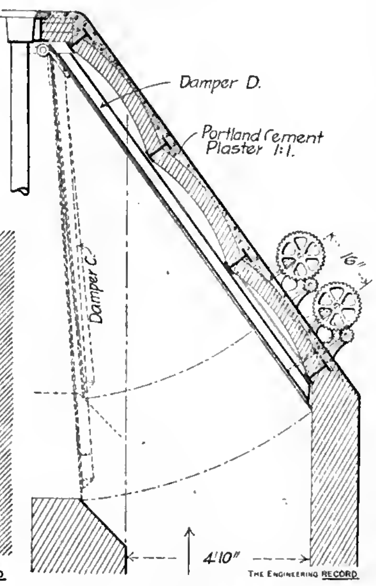
Condensing Water Intake.



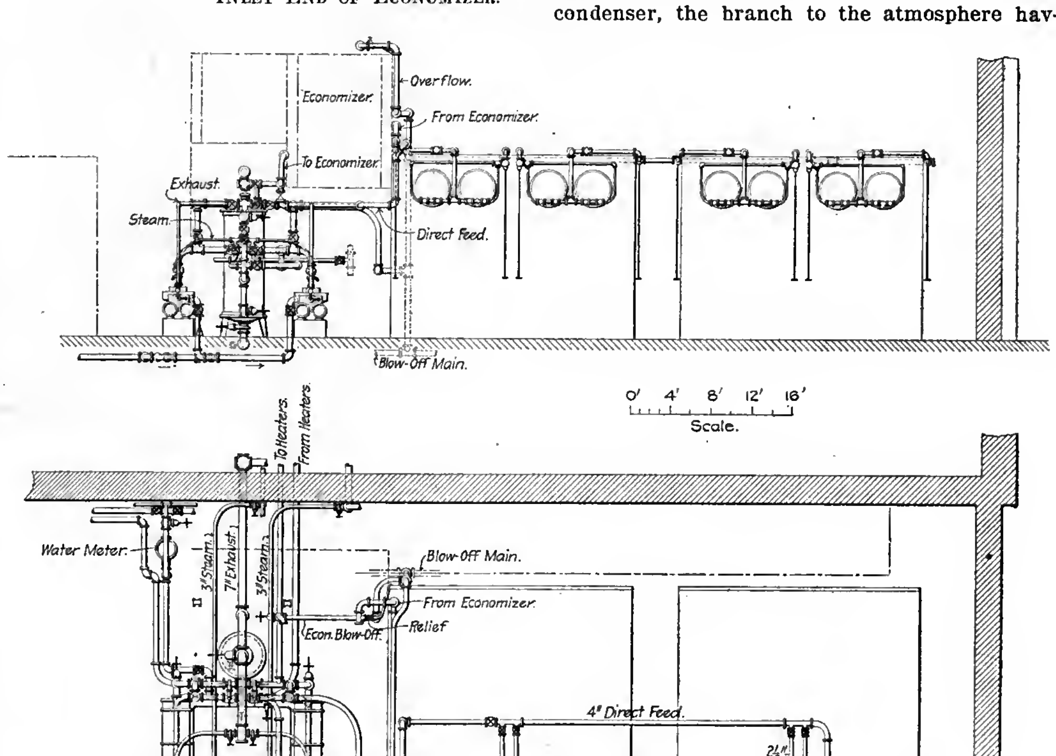
Plan of Economizer.

hinged at the top and is lifted or lowered by means of a chain at the bottom, the winding drum operated in each case by a hand crank through spur gearing. The dampers at the exit of the passages are suspended by chains at their axes, the chains passing through the top of the setting and being twisted to turn the dampers. The economizer extends below the by-pass passage and the clean-out doors are located on the inner side of the economizer wall and under the by-pass passage. The chimney, which is located a short distance outside the boiler room, is of brick of the double-shell type, with a constant inside diameter of 9 feet and a height above the grate bars of 252½ feet.

The steam from each boiler is carried from the cross-connection joining the outlets of the two superheating coils in each boiler to a 16-inch header by means of a horizontal 8-inch wrought-iron pipe bent horizontally. This pipe is connected into the side of the header, with a valve at the cross-connection and at the header. The header, which is of steel and supported by cast-iron roller bearing chairs fastened by extension pedestals to the top of the smoke duct, is divided into four sections, corresponding to the four boilers, by gate valves. These are readily accessible from the roof of the smoke passage. The supply pipes to the engines already completed rise 8 inches in size in a long upward bend to a steam receiver, which is suspended in position by means of a special bend of gun metal passing through and anchored in the partition wall. From the top of the receiver, the engine supply continues 9 inches in diameter, with resultant reduction in velocity, roughly 6,000 feet per minute, and passes through the gun metal bend into the engine room where it reaches the high-pressure engine cylinder by means of long downward bend. The receivers are 30 inches in diameter and 6 feet high and, besides being a reservoir of steam, used to lessen the chance of pipe vibrations by the periodic cut off of steam and to supply a sudden demand of steam, act as separators. These receivers and each section of the header are drained into a 3-inch drip main suspended below and run parallel with the header; from this the water is conducted into a Holly receiver and returned, together with other clean high-pressure drips, into the boilers by means of the Holly system. For the supply of the various pumps, a 5-inch main is carried along the partition wall in the basement of the engine room, this main supplied by a 5-inch pipe from each end of the main header. The high-pressure piping throughout is provided with the Vanstone joints with copper gaskets.



Inlet End of Economizer.



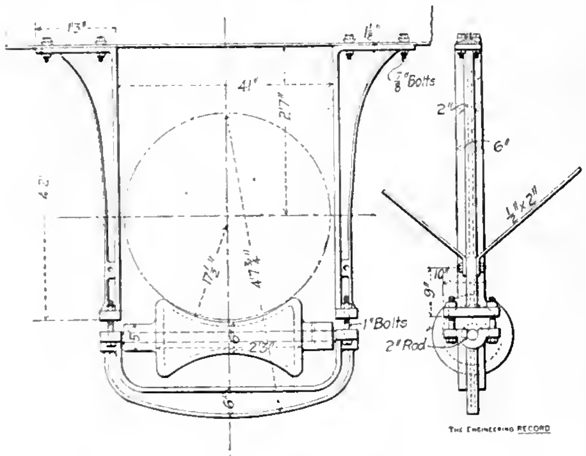
Plan and Elevation of the Feed Piping.

There is at present in the engine room two 500 kilowatt electric generating units, a 1,500-kilowatt unit approaching completion and space for another 1,500-kilowatt unit, making the capacity of the initial plant when entirely installed, 4,000 kilowatts, with a continuous overload capacity of 1,000 additional kilowatts. The units consist of McIntosh & Seymour vertical cross-compound engines and General Electric three-phase 60-cycle alternators, the alternator and a fly-wheel being located between the two cranks. The governing mechanism is of the interia fly-wheel type, under control of a ⅛-horse-power motor, mounted on the wheel and controlled from the switchboard, for moving the weights to the desired position and thus securing facility in synchronizing. The smaller engines have 18 and 38-inch cylinders and a common stroke of 42 inches, and the large engine 31 and 64-inch cylinders and 48-inch stroke. The rotative speed of the smaller units is 120 revolutions per minute and that of the large combination, 120 revolutions; the alternators generate a voltage of 2,300 volts. Current is transmitted, at this pressure, throughout Cambridge, being stepped down by transformers at the points of use. The switchboard, which was built by the General Electric Company, is located against the outside wall of the engine room, and the conductors pass out of the building through a wiring tower, which is a small shaft built against a rear corner of the boiler room.

Each engine is provided with a receiver for the passage of the steam from the high-pressure to the low-pressure cylinder, and the high-pressure cylinder is jacketed for high-pressure steam and there is a high-pressure steam coil in the receiver. The condensation from each source is returned to the boilers by means of the Holly system. The exhaust steam from the low-pressure cylinder passes first through the main heater and then may be conducted to the atmosphere or to the condenser, the branch to the atmosphere having the usual back-pressure or relief valve for use when the condenser is in operation. The heaters were made by the Whitcock Coil Pipe Company, of Hartford; for the smaller engines, they contain 165 square feet of heating surface, and for the larger, 334 square feet.

The condensers are of the Blake vertical twin type of jet condenser, with 12-inch steam cylinders, 25-inch air pump and 18-inch common stroke. The reciprocating members rise into the engine room, and a light well has been built around them, giving considerable light to the basement in that way, in addition to that obtained from the basement windows. The condensers are located on the far side of the engine foundations from the boiler room and the main exhaust line is carried to the outside of the building independently of the exhaust from the pumps and auxiliary machinery. The exhaust piping throughout is of cast iron.

The condensing water is drawn from the Charles River through a tunnel to a well near the power house and from there through a 12-inch injection pipe. The tunnel is circular in section, 4 feet 6 inches in diameter, of 12-inch brick walls and about 85 feet long. Its inlet is protected with a grill of 1-inch iron bars, set vertically. The well is 8 feet 6 inches in diameter, built with concrete walls 24 inches thick, and capped with a cast-iron cover; it is about 23½ feet deep. It is fitted with a partition of wood with a copper-wire screen in the bottom, the partition dividing the well into two compartments, one in which the screened water is taken through the enlarged mouth of the injection pipe and the other in which debris collecting outside the screen can be removed. The screen consists of ⅛-inch copper wire, with ¾-inch mesh and has a free area of about 14 square feet. The discharge pipe from the condensers, which is 30 inches in diameter, ends 75 feet beyond the condensing water intake.



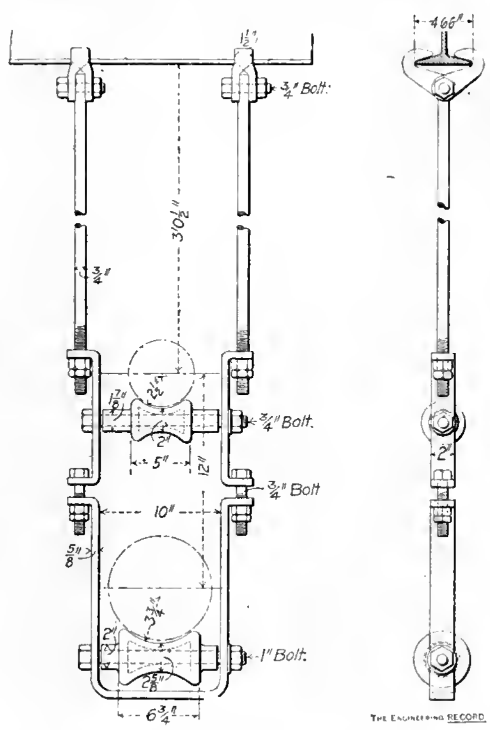
Hanger for 36-Inch Exhaust Pipe.

The condensing water piping throughout is of cast iron, and in the power house is carried in a cement lined trench below the basement floor.

Besides the condensers and the boiler-feed pumps, which are supplied from the auxiliary steam main, there is a steam-driven exciter unit in the basement, supplied from the same source. This consists of a 10x12-inch Armington & Sims horizontal engine, running at 275 revolutions per minute, and a 120-volt Westinghouse direct-current dynamo of 25 kilowatts capacity. This is intended to supply the field current for starting the alternators, but under normal running conditions the field excitation will be obtained from a 35-kilowatt motor driven set in the engine room. This comprises an induction motor directly connected to a direct-current dynamo. Space has also been reserved for a larger set to care for the entire plant upon the addition of the fourth unit. The three make a very flexible and practically a duplicate combination for excitation.

Feed-water ordinarily is taken from a rain water tank of 40,000 gallons capacity, and when necessary, from the city water mains through a water-meter. No purification or water softening has been found necessary. There are two feed-pumps situated, as stated, underneath the economizer, one the reserve of the other. These are of the Blake outside packed plunger type, designed for high-pressure work, with 6½-inch plungers and duplex compound steam cylinders, 8 and 12 inches in diameter and 12 inches stroke. They deliver the water usually through the main heaters in the main engine exhaust pipes, then through the auxiliary heater, for the utilization of the exhaust from the pumps and auxiliary apparatus, then through the economizer and into the boilers. Any one of the heaters may be by-passed, as may also the economizer. The feed-pumps are governed automatically by means of a Locke governor. The by-pass around the economizer is extended into an independent boiler feed main, while that from the economizer makes a second feed main. The method of taking connections from both mains, which, it may be pointed out, can be connected together, is shown in an accompanying drawing of the feed piping systems. The auxiliary heater is of the closed type, of the same make as the main heaters, and contains 500 square feet of heating surface.

An extensive oiling system has been installed



Hanger for a Pair of Pipes.

for the generating machinery. It includes a duplicate installation of filters and oil tanks under a compressed air system of circulation. The equipment is located in the basement against the engine foundations and facing the basement windows. The oil tanks rest on brick piers on the basement floor and are 4 feet in diameter and 3 feet high with dished heads, the heads turned in the same direction. The filters, which are of the Cross make, are 35 inches in diameter, 4 feet 4 inches high, supported immediately above the level of the top of the oil tanks. The compressed air is furnished by a 5-horse-power motor-driven Ingersoll-Sergeant Drill Company air compressor, and a compressed air tank 3 feet in diameter and 6 feet 9 inches long is provided, suspended from the basement ceiling. A 1-inch pipe leads from the air tank to the tops of the two oil tanks, with valves so that either tank can be put into use, and there is a branch to this pipe for filling with fresh oil. The oil is forced from the bottom of each tank through 1-inch piping to the lubricating system. On its return it is delivered by 2-inch piping into the filters and thence by a ¾-inch pipe into either oil tank to be recirculated. The air is maintained at 50 pounds pressure.

The power plant was designed by Messrs. Sheaff & Jaastad, of Boston. The general contractor for the structure, including the chimney, was Mr. F. B. Gilbreth, of that city, and the contractor for the piping was the Walworth Manufacturing Company. It will be interesting to note that in the construction of the foundations for the building and machinery, the portable gravity concrete mixer made by the Contractors' Plant Company was used, combined with the concrete set-up invented by Mr. Gilbreth, which is moved away from the mixed concrete instead of removing the concrete from the concrete mixer. Mr. D. E. Badger, chief engineer of the plant, supervised the construction, while the electrical end was looked after by the chief electrician, Mr. W. R. Eaton.

The Hydraulic Power Plant of the Riverside Power Company.

The city of Riverside, Riverside County, Cal., owns an electric generating system driven by steam, using crude oil as a fuel. In addition to the steam plant the city buys electricity from several different sources and sells electricity for lighting and power. The conditions of irrigation around and in Riverside are such that the plants pumping water for irrigation, either from wells or from the various canals, are considerable consumers of power, and the majority of these pumping plants may be so operated as to utilize the surplus electric power without materially interfering with the lighting load. Some of the choicest orchard land is above all existing or projected canals, and the city has been making a determined effort to increase its sales of electric power to the irrigators of such land, and, in fact has somewhat oversold the supply.

The Riverside Power Company is one of several companies that were gotten up to sell electricity to the city at wholesale. The Riverside Power Company utilizes the water supply of the Santa Ana River by passing it through a canal which heads three miles below the city and extends six miles along the bank to a power station, where two 300-kilowatt General Electric generators are to be driven by turbines. The design of the system, as worked out in a report of Samuel Storrow, consulting civil engineer, of Los Angeles, Cal., included a concrete-lined canal having a capacity of 120 cubic feet per second and leading to a reservoir capable of storing 12 hours' flow. The original scheme provided for a power plant so designed that the day load on the electric equipment could be taken care of by one generating unit, and the night load by two units, the intention being to allow the reservoir to fill up during the day by the excess of the capacity of the canal over the demands of the wheels, and then to allow the reservoir to empty through the power house during the peak of the lighting, thus giving a fluctuating delivery to correspond with the fluctuating demand upon the system.

The intake of the canal is placed at the "Narrows" of the Santa Ana River, where its channel is crossed by a granite dike and the wide valley contracted as the river enters the canyon. This is a particularly strong and satisfactory site for a diversion weir, and has but one objection—that the river carries an extraordinarily large amount of sand, which is constantly moving down stream at all stages of the river and more especially at times of flood. This difficulty was obviated by building sand-boxes, or "blow-offs," in the bottom of the canal at a point about 1,000 feet below the entry, where the canal enters the flume and passes along the side of a vertical cliff and directly over the left bank of the river.

The great fluctuation in the discharge of the river, varying from 5,000 cubic feet per second or more in the winter floods to 30 cubic feet per second in the short season of low water in July, renders it necessary to have two points of diversion, one at the above-mentioned granite dike for use during low water, and one at a point about 600 feet down stream for use during floods, when the works at the dike will be entirely submerged and the upper part of the canal entirely filled by the drifting sand. An excess of grade is given to this upper part, and the gates are so arranged that as the floods subside the upper 600 feet of the canal will be cleared of the sand by sluicing it out in such a way as will restore the upper intake to use without interfering with the operation of the system.

Contracts have been let for the grading, for the water wheels, and for the electric plant at a price within 3 per cent. of the estimates of the engineer. Active grading has begun under the charge of Mr. H. Clay Kellog, who has contracted to do the necessary civil engineering. The estimate for the grading and concrete is $42,000. The company has a contract with the city of Riverside by which the city will purchase all the electricity that the company can generate and pay therefor at the rate of $6 per horse power per month, for deliveries at the distributing station in the city of Riverside, during a term of thirty years. The exact design of the consulting engineer has been carried out, excepting that the canal is being built with a capacity of 140 cubic feet per second, and the reservoir, which was suggested to enable the system to give a larger output during the peak of the load, is to be omitted.

The electric plant is to be furnished by the General Electric Company, and includes the following: Two alternating, 3-phase, revolving-field, 12-pole, 300-kilowatt, 11,500-volt, 50-cycle generators, with base, and two bearings and shaft arranged for water-wheel connections, to operate at 500 revolutions per minute; two 4-pole, 17-kilowatt, 125-volt exciters, arranged to operate in connection with a water-wheel or by an induction motor, at 750 revolutions per minute; and three 200-kilowatt, 50-cycle, air-blast transformers, primary circuit 10,000, secondary 2,300 volts. The switchboard arrangement will consist of two 300-kilowatt, 11,500-volt generator-panels, one induction motor panel, two exciter panels, one 600-kilowatt, high-tension transformer panel, one 600-kilowatt, low-tension feeder panel, and General Electric lightning arresters. Form K automatic oil switches will be used throughout.

The officers of the Riverside Power Company are: President, Hon. E. W. McGraw, of San Francisco; vice-president, Charles H. Toll, of Los Angeles, and secretary, W. E. Pedley, of Riverside. The other directors, in addition to the officers, are G. D. Cadwallader and Myron Alguire.

The Wachusett Dam, at Clinton, Massachusetts, for the Boston Metropolitan Water-Works, is progressing steadily. According to the recent monthly bulletin of the excursion committee of the Boston Society of Civil Engineers, rubble masonry in the main part of the dam is being laid by ten derricks with a combined capacity of about 500 cubic yards of masonry per day. These derricks are of the stiff-leg type, are fitted with large bull wheels and operated by compressed air. Each derrick is self-contained and can be lifted bodily by the Lidgerwood cableways and set in a new position from time to time, as required by the progress of the masonry.

Electrical Apparatus in English Coal Mines.

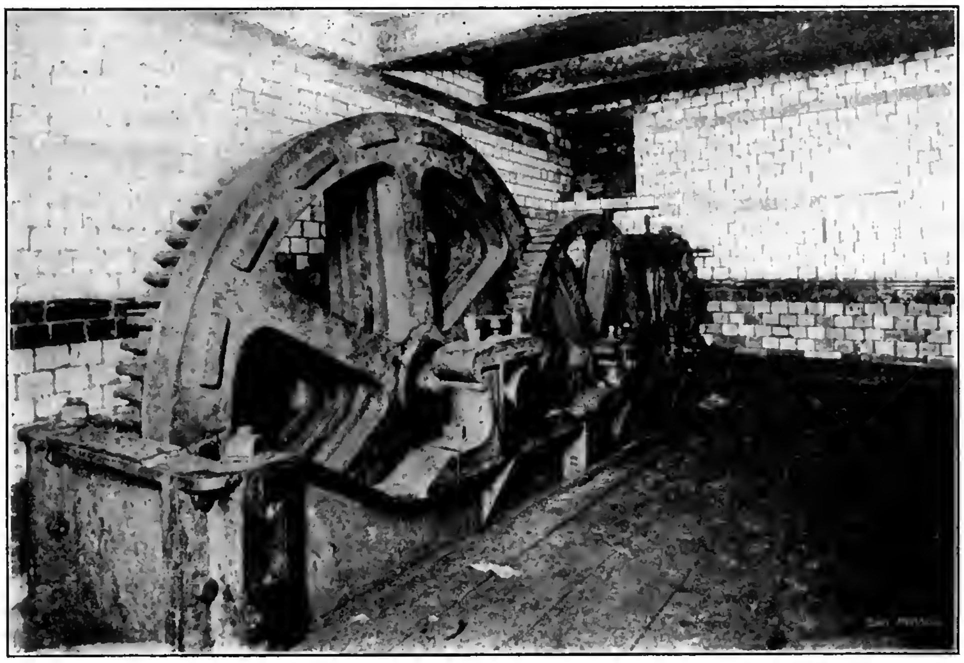
The price of coal in England is steadily rising, shafts are being carried deeper and deeper, and, the richer veins having been exhausted, the thinner veins, containing often poorer grades of coal, must now be developed. These things have put the British operator upon his mettle, and he has taken up the latest and most improved methods of coal mining very rapidly. He has adopted for power transmission alternating currents and induction motors, which, for mining work and especially coal mining, are stated to have many great advantages over direct-current machinery. The foregoing facts are well illustrated in the following brief description of the electrical plants recently installed at a number of English coal mines.

The Sneyd Colliery, at Burlem, Staffordshire, has recently put in a complete alternating current equipment. Current is generated by a Westinghouse three-phase alternator, direct coupled to a Westinghouse steam engine. Westinghouse induction motors aggregating about 1,000 horse-power are used for driving "main-and-tail" and "endless" rope hauling engines, for pumps and for several other auxiliary purposes. The hauling gears with their electric motor equipment are shown in the accompanying photographs. These mines are gaseous, and the use in them of direct current machinery would have been dangerous. The induction motor, however, on account of the fact that it has no moving contacts to spark or flash is well adapted for use in such locations.

The Clapwell Colliery, of Chesterfield, has recently installed two three-phase Westinghouse alternators, one of 225 kilowatts capacity and the other of 20 kilowatts, together with a 6-kilowatt, direct current exciter. The British Westinghouse Company also furnished ten induction motors, aggregating 280 horse-power. The Oxcroft Colliery, of Chesterfield, has installed two three-phase Westinghouse alternators, each of 200 kilowatts capacity and operating at 440 volts, 30 cycles per second and 100 revolutions per minute. The equipment includes two exciters, each of 11¼ kilowatts capacity, and a small generator of 1½ kilowatts capacity; also 13 Westinghouse induction motors with an aggregate capacity of 300 horse-power and a complete switchboard outfit for the entire plant.

About 4,000 horse-power of Westinghouse electrical apparatus is about to be installed in the several collieries owned by the Stavely Coal & Iron Company, of Chesterfield. The Sherwood Colliery, of Mansfield, have purchased two three-phase Westinghouse alternators, each of 50 kilowatts capacity, operating at 440 volts, 60 cycles per second and 900 revolutions per minute, and three direct-current, multipolar generators of about 12 kilowatts aggregate capacity. At the Tredegar Iron & Coal Co.'s collieries, in Monmouth, a complete power equipment is being installed, comprising two 150-kilowatt, three-phase Westinghouse alternators, two exciters, each of 7½ kilowatts capacity, and ten induction motors ranging in size from 50 to 5 horse-power and aggregating 220 horse-power.

The Bolsover Colliery Company, of Chesterfield, has decided to adopt electric driving to a considerable extent, and has placed a large order with the British Westinghouse Co., including a 180-kilowatt, three-phase alternator, together with exciter, a 200-horse-power induction motor, complete switchboards, etc. The Stanton Iron Works Company, of Pleasley, will equip its collieries with electrical apparatus, including about 150 kilowatts in generating capacity and 100 horse-power in motors, all purchased from the British Westinghouse Company. The Tyrdail Collieries, of Carmarthen, have contracted for an electric power installation consisting of a 60-kilowatt, three-phase, Westinghouse alternator, exciter, switchboard, and about 50 horse-power of induction motors. The New Cross Hands Colliery, of Lanelly, has purchased an electrical power equipment consisting of a 125-kilowatt, direct-current Westinghouse generator, with switchboards, etc., complete, and several Westinghouse direct-current motors.



Induction Motor Operating "Endless Haulage," Sneyd Colliery, Staffordshire.

From the above examples it will be apparent that the British manufacturers are by no means slow to see the economies of electric driving.

The Panama Canal Company can transfer to the United States "a good, valid and unencumbered title," according to the opinion of Attorney General Knox, officially rendered October 25, after an exhaustive research. The recent French premier, M. Waldeck-Rousseau, confirms this by the statement: "The United States will acquire the finest and most impregnable title of ownership to the property transferred, and will assume no other obligations than those stipulated in the contract of transfer itself."

Cooper's Bridge Foundation Specifications.

General specifications for foundations and substructures of highway and electric railway bridges have been prepared by Mr. Theodore Cooper, consulting engineer, New York, and will soon be published for the use of builders and engineers. Through Mr. Cooper's courtesy we present in advance selected illustrations and abstracts from the text which give some valuable data and indicate the character of the specifications. Mr. Cooper briefly analyzes the general cases, points out important conditions and requirements and describes typical structures, calling attention to essentials of their design and details of their construction. These features add materially to the value of a simple specification. The author has thus provided a general standard which will be very useful in designing and specifying work of this class, for which there is little formulated data generally available. There are 24 pages of text classified under numerous headings, two appendices and twelve full-page engravings of general designs and details of typical substructures. The text describes and specifies simply and clearly good and suitable structures and methods which are not complicated by elaborate calculations or requirements difficult for an ordinary builder to follow. The drawings are exceptionally clear and well arranged.

In the preface the author notes that while standard specifications are available for highway bridge superstructures there are none for their substructures and that he has therefore endeavored to illustrate the more common forms of substructures and foundations suitable for highway bridges and give the required proportions for all ordinary cases, with instructions and specifications for their construction.

Standard proportions and specifications for the substructures of highway bridges will not only broaden the competition for their construction, but will result in obtaining a better class of substructures than has been generally the case heretofore. They will also enable in many cases the local artisans to proportion and build the same.

The author excludes from consideration difficult foundations in deep water or those requiring pneumatic or other special appliances or works of such expense as would demand special study of the conditions to determine the best or most economical solution; also city bridges and long-span bridges, where a higher and more elaborate class of substructure may be demanded and justified.

Attention is called to the necessity for a careful determination of the regimen of the river, the conditions of flood, character of bottom scour, traffic, and the requirements of navigation to aid a careful judgment in the selection of the type of substructure, and it is recommended that where the local knowledge of the river and its banks and bottom is not complete and certain, a special examination should be made by an experienced engineer. In many cases the location of the piers is determined by natural conditions: where it is a matter of choice the most economical arrangement of spans can be found by appendix A.

The character of the bottom on which piers and abutments must be founded is considered under three classes, first, rock; second, hard ground, as hard-pan, gravel, compact sand or hard dry clay; third, soft ground, as soft or wet clay, silt or mud, whose sustaining power must largely depend upon the frictional resistance of long piles or piles driven through the soft material to an underlying material of a harder character.

Several paragraphs are devoted to instructions for the preparation of the site to receive the foundations. Where the footings are carried down to rock the excavation should be made to sound hard surface and filled up to a level or stepped surface with concrete.

In hard ground the material should be excavated to a depth below the action of frost or scour by surface currents, with a minimum depth of 3 feet, if above the water. And for foundations in the water, to a depth sufficient to be below any possible scour by the river currents (usually increased by the placing of piers in the stream) and to give the piers sufficient foothold to resist displacement by the shoving action of floods, ice or floating material.

Where the foundations are on or near the banks of streams or on sloping strata they should be carried deep enough to insure them from slipping by the sliding of this underlying material.

Where the material is liable to be softened, scoured or undermined by water action or where under water the foundations cannot be carried deep enough to be beyond any possibility of being affected by scour the bottom should be piled.

In soft ground the material should be excavated to a stratum of harder material or else it must be excavated to a depth where the soil is permanently wet, if on land, and below ordinary scour, if in the water. Piles spaced not over 2½ feet centers should then be driven over the whole area to a "good refusal." The piles should be cut off or driven to one level and then covered with a timber platform or a layer of well-rammed concrete 2 feet thick, upon which to start the masonry. In all cases as the masonry is built up, the remaining openings of the excavation should be refilled with good material well rammed in place.

The general requirements provide that wood shall be used only where it will be permanently wet. Metal is not allowed in contact with the soil except for the shells of deep water piers and for piles. Concrete must be laid in the open when possible. The tops of viaduct piers must be at least 18 inches above the surface of the ground, and all bridge seats must be single stones or concrete blocks with an area double that of the metal base supported. The size and refusal of piles is specified, and 8 to 12 feet in wet gravel, sand or stiff clay, and 20 to 40 feet in soft clay or silt given as the minimum penetration. The instructions for framing and connecting timber work give particulars about spiking, notching and dovetailing. Particular care is taken to make the requirements for cement so simple and the tests so easy, that good results can be obtained under ordinary local conditions, without expert services. The character of the sand and gravel is described and directions are given for making and using the concrete and mortar. Mortar shall be made with 300 pounds natural cement and 12 cubic feet of sand, or 375 pounds Portland cement and 16 cubic feet of sand. Concrete shall be made with 375 pounds Portland cement to 8 feet of sand and 16 feet of ¾-inch broken stone or gravel, or with 300 pounds of natural cement, 12 feet of sand and 24 feet of broken stone or gravel, the latter formula being allowable when the foundations below the surface of the ground are not exposed to weather or running water.

The detailed specifications for rock faced broken-range masonry, for rock faced, coursed masonry and for monolithic concrete masonry are simple and comprehensive and conform to the standard requirements for good work. Steel shells for concrete piers are required to conform to the requirements of Cooper's highway bridge specifications for 1901, and the thicknesses, riveting and bracing are specified.

The second part of the specifications includes descriptions of the design and construction of different types of foundations and is intended to be mandatory as well as explanatory. Plans and elevations are given for the different classes of ordinary bridge substructures, with the leading dimensions indicated by letters corresponding to tabulated values giving the proportions for varying sizes and assumptions.

Methods of constructing foundations on submerged soft soil are illustrated by Plate 2. One figure shows a sheet pile and puddle cofferdam enclosing an excavation in which piles are driven and capped with concrete or a timber platform to receive the masonry. Another figure shows piles driven in an open dredged excavation, cut off level, and filled around with broken stone to receive the solid timber bottom of a caisson, which is floated into position and sunk on the pile tops by building the masonry inside, after which the detachable sides of the caisson are removed, leaving the bottom permanently engaged between the masonry and the pile tops.

Plate 2 shows a plain masonry abutment, on hard bottom and without wing walls, which is proportioned for spans of from 75 to 200 feet. Plate 3 shows a masonry abutment and wing wall on hard bottom. Plate 4 shows a long and narrow masonry river pier with cutwater, on hard bottom, and gives tables of dimensions for spans of 50 to 300 feet.

To spread the loads and weight of the masonry over soft or unequal soil or to facilitate the founding of piers under water, it is often expedient to use timber platforms, grillages, caissons or cribs.

Timber platforms consist of two or more layers of closely-laid timber alternately crossing each other and thoroughly spiked together to act as a solid platform. The thickness and size of each platform must be such as to distribute in a proper manner the full load over the piles, where used, or over the underlying material, without exceeding the carrying capacity of such material.

Timber grillages are similar layers of alternately crossing timbers laid with open spaces about the width of the timbers, so they can be weighted with gravel, stone or concrete, to facilitate the sinking and placing into position. They are generally floored top and bottom with plank.

Open caissons, the only kind of caissons here considered, are timber platforms or grillages with water-tight wooden sides attached thereto (usually so as to be removable after the work is completed), so as to form a water-tight box in which the masonry can be built in the dry; and which can be floated into place and sunk in proper position, either upon the pile heads or on the prepared bottom.

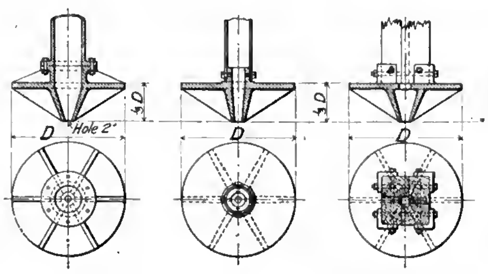
Timber cribs are formed of alternate longitudinal and transverse timbers, notched, dovetailed and spiked together at their crossings, so as to form a rigid structure divided into a series of pockets several feet square. The open spaces of the ends and sides may be filled in with timber, so as to make them close and solid. A portion of the pockets are floored over so they can be filled and loaded with broken stone or concrete to sink the cribs into position upon the bottom or into the mud to a depth sufficient to get the desired stability. After the crib is in proper position the floored pockets should be loaded and the open pockets dredged until the desired depth is obtained. For hard bottom, where it is not possible to obtain a level surface by dredging, the bottom should be carefully cross-sectioned and the bottom of the crib built to the correct shape to get a proper bearing.

The author considers that the use of cribs for foundations may be justified where there is no possibility of their settlement or displacement, and that cribs may be sometimes used to protect and hold the footings of cylindrical piers on hard bottom, as shown by Plate 7, or to give lateral stiffness to pile foundations in soft mud or deep water, as shown by Plate 9, which is not here reproduced. This plate gives a plan and elevation of a group of piles driven through a pocket in one end of a crib which is sunk into the soft bottom with rock ballast in pockets both sides of the piles. The top of the crib is a little below low water and the tops of the piles at a little higher level are capped with a platform of crossed timbers, also below low water, which receive the masonry pier for one truss of the bridge. There is a similar separate pier for the other truss at the opposite end of the crib. The crib is made with notched and dovetailed joints and with square timber except that the floors of the ballast pockets are made with round timber. The well through which the piles are driven is lined on the sides with vertical planks, and is filled with small broken stone or gravel packed around and between the piles.

Attention is called to the necessity for providing for river piers foundations which are below the possibility of scour. Abutments should be designed as retaining walls for the earth banks behind them, with weep holes or other provision for drainage, and the earth deposited back of such walls should be carefully rammed in layers as the masonry is built up. Plate 5 shows a square tower pier which is one of two separate piers supporting the superstructure instead of a long pier where there is quiet water and no danger from ice or other floating material. It has an extended footing on an offset timber grillage with a close laid plank floor top and bottom, and is sunk, with its diagonal parallel to the current, in a dredged excavation and filled around with broken stone.

Plates 6 and 8 show piers on soft bottom with piles having their tops enclosed in steel shells which reach down into the ground and are filled with concrete. One of them has a single oblong shell with rounded ends, and the other has two separate cylindrical shells connected by riveted transverse bracing above low water. With each there is a table of dimensions and numbers of piles required for different classes of bridges and for spans of 50 to 250 feet. The bottoms of the shells should be sunk below danger of scour, by loading and interior excavation, and they should be filled with piles driven to good refusal and cut off at low water level. The piles should be kept 4 to 6 inches clear of the shells and the spaces between the piles must be less than the size of the smallest pile used. For the oblong shells this close spacing need only apply to the end portions, symmetrical with the center of the bearings of the trusses. The spaces between and about the piles must then be well filled and rammed with Portland cement concrete. The shells above low water shall then be pumped dry and filled with Portland cement concrete in well-rammed layers to the top, where it must be finished off in proper shape for the bridge seats and drainage.

For material which can be excavated from the inside of shells to a sufficient depth below possible scour, but which does not need piling; the shells should be sunk to the proper depth, the bottom sealed against the admission of water by depositing concrete through pipes or in bags, then pumped dry and the interior properly filled with Portland cement concrete. Or, the bottom may be dredged beforehand to a proper level and the shells bolted rigidly to a timber platform or grillage and then sunk as an open caisson.



Part of Plate 11.—Disk Piles.

For rock bottom, where it is possible to fit the platform to the rock surface, this form may be used, but where the weight of the piers is not sufficient to give abundant security against the shoving action of floods, ice or floating material the platform should be anchored securely to the rock by anchor bolts.

For rock or hard bottom cylinder piers may be steadied and also protected from scour by a surrounding crib, as shown on Plate 7. After the crib is placed and sunk by filling the floored pockets with broken stone or concrete, the cylinders should be lowered into place through the open pockets provided for them; then the open spaces outside of the cylinders should be well filled and rammed with Portland cement concrete to the full depth of the cylinders. Then the interior of the cylinders should be pumped dry and filled in the usual way with concrete. Where the crib cannot be sunk to the rock, owing to the overlying mud, sheet piles or sheeting can be driven around the periphery of the open pockets to the rock and the mud removed, before placing the cylinders or depositing the concrete.

The permanency of the wooden crib in fresh water and the protection of both sides of the metal shell by cement concrete gives this style a superiority over those where the outside of the shell is in direct contact with the water and hence subject to continuous oxidation.

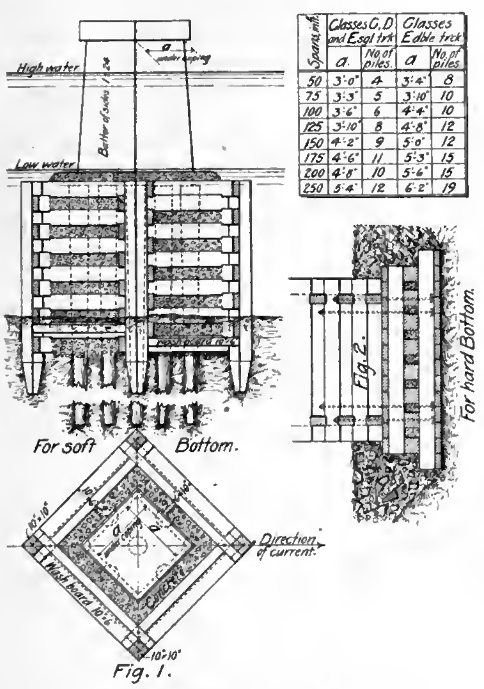
Little or no faith should be put in the claim that when the metal shells do finally rust away, the concrete core will be able to serve the full purpose of a pier, even for the best concrete work; and when the concrete is deposited through the water as has been the usual custom heretofore it will probably be found to be no better than loose stone.

In many localities instead of using metal shells, wooden boxes, as shown on Plate 10, can be advantageously substituted, and should be placed diagonally to the current. The timbers being entirely under water, will be permanent in fresh water, or where the waters are free from the teredo or limnoria.

Low viaduct piers should be built of masonry with a minimum base 3½ feet square for hard bottom for even the shortest spans. The bearing area should be increased 50 per cent. for moderately good ground and should of course be increased according to the length of span and doubled for double track electric railways.

Submerged foundations may be built on disc or screw piles, which, below the mud line should have timber or cast-iron shafts. Disc piles are sunk by the aid of a water jet, to a level sufficiently below any possible scour, so as to have at all times a depth in the sand of 6 to 10 feet. For silt or soft material, the disks should penetrate to a good stiff bottom or else to a depth such as would be required for good piling in the same material.

The discs shall be of cast-iron and of the sizes given in the tables for the particular



Spans, ft.	Classes C, D and E sgl trk a.	Classes C, D and E sgl trk No of piles.	Classes E dble trck a	Classes E dble trck No of piles
50	3'-0"	4	3'-4"	8

125	3'-10"	8	4'-8"	12
150	4'-2"	9	5'-0"	12
175	4'-6"	11	5'-3"	15
200	4'-8"	10	5'-6"	15
250	5'-4"	12	6'-2"	19

Plate 10.—Wooden Box Foundation.

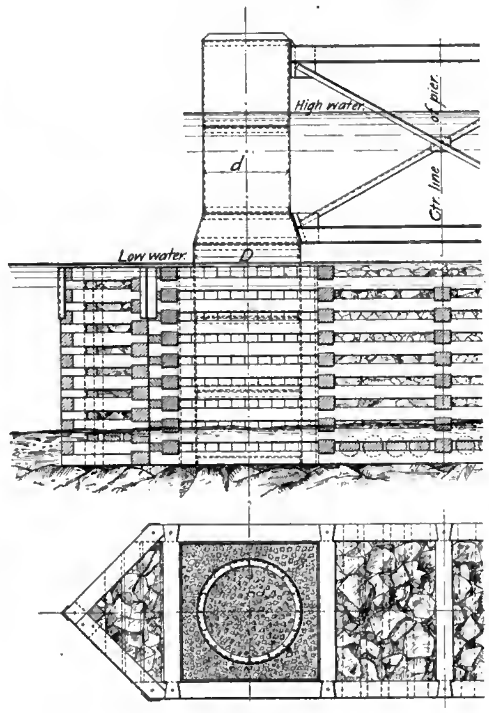

Plate 7.—Cylinder Pier on Rock, with Crib Protection.

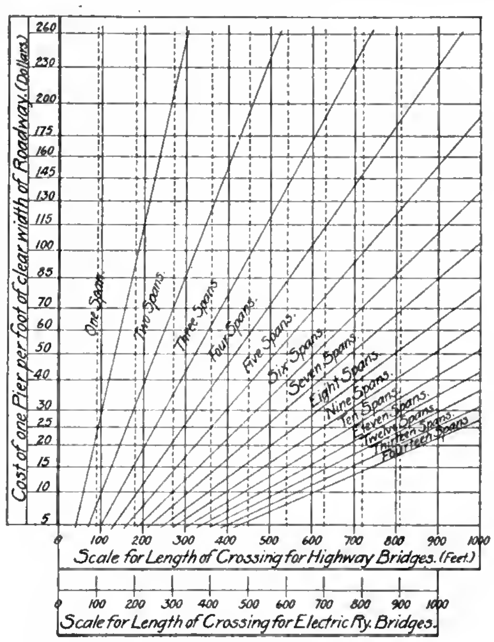

Plate 13.—Diagram for Determination of Economical Spans.

span as proposed. The thickness of the metal in the top plate and thicker parts of the cone and connecting ribs should not be less than 1¼ inches for discs 24 inches in diameter, or 1½ inch for larger sizes. The point should be pierced with a vertical conical hole at least large enough for a 1½-inch jet pipe.

Although screw piles are expensive to make and drive, their use is sometimes justified. They should be designed throughout to resist very heavy torsional stresses.

The best pitch for different materials is a matter of experience and judgment. In general it should be from 1/3 to 1/6 of the diameter of the screw, the larger pitch being for soft material and decreased as the material increases in toughness of penetration.

The points of the screws may be made of various forms to suit the material, which is to be penetrated, viz., gimlet pointed for gravel, serrated for soft rock or coral, blunt for sand or fitted for the assistance of the water-jet in sand or gravel.

Plate 12 shows three screw piles with five different types of points, all of which are hollow castings, bolted to the pile shafts, which in two cases are steel or cast iron pipes and in the third a solid square timber. An accompanying table gives the value of the diameter of the shaft and screw for different types of bridge and lengths of span.

Appendix B gives tables of the amount of masonry in piers and abutments for spans of from 100 to 300 feet, calculated for heights of 10 to 30 feet between top of coping and bottom of footing, and for roadways 12 feet wide, 20 feet wide, for single and for double electric car tracks. The arrangement of piers to give the minimum total cost for the bridge is discussed in Appendix A, accompanied by Plate 13, in which, to provide for bridge of different widths, the cost of one pier per foot of clear width is used; the clear width for highway bridges being the width of roadway and sidewalks, and for electric railway bridges, 14 and 26 feet for single and double track bridges.

The vertical column at the left hand of the diagram (scale of square roots) gives varying costs per foot of clear width for one pier, including towers, if there be any.

The horizontal line at the bottom gives the length of the crossings between centers of abutments (one scale for highway and one for electric railway bridges.)

Having made an estimate of the cost of one pier (see Appendix B) of the required dimensions as per the specifications, divide it by the clear width of the proposed bridge. Then follow the horizontal line through this value to the vertical line through the length of the crossing and the number of spans given for that point will be the required number for economy.

Example: Crossing, 500 feet; width of roadway, 20 feet and two sidewalks, each 5 feet.

Should one pier cost $900 or $30 per foot of width, use 7 spans.

Should one pier cost $1,800 or $60 per foot of width, use 5 spans.

Should one pier cost $4,000 or $133 per foot of width use 3 spans.

Of course, many features of interest in Mr. Cooper's specifications have not been given in this abstract.

In the Chicago Drainage Canal Litigation a motion was recently filed in the Supreme Court of the United States to discharge the case because of lack of action by the prosecutor, the State of Missouri, an entire term of the court having elapsed without an effort by the complainant to further the prosecution.

The Use of Slag in Cement Making.

Extracts from advance sheets of a report by Edwin C. Eckel on the Utilization of Iron and Steel Slags, in "Mineral Resources, 1901."

Slag cement, properly so called, is the product obtained by pulverizing, without calcination, a mixture of granulated basic blast-furnace slag and slaked lime. This product, though in reality a member of the class of pozzuolanic cements, is usually marketed as "Portland cement," in spite of the fact that it differs from a true Portland cement in method of manufacture, ultimate and rational composition, and properties. Six or eight plants are at present engaged in the manufacture of this material in the United States, the production for 1901 being 272,689 barrels. The writer has discussed the manufacture of slag cement in detail in a recent publication. A brief résumé of the technology of the material in question is here given.

As to composition, the material used in the manufacture of slag cement must be basic blast-furnace slag. Tetmajer stated that the ratio CaO/SiO_2 should never be less than unity, and that the best results were obtained when the ratio Al_2O_3/SiO_2 gave a value of 0.45 to 0.50. Prost and Mahon later obtained good results from slags in which the alumina was much higher than indicated by Tetmajer's ratio, and analyses of slags used in practice are shown in the following table, with the ratios CaO/SiO_2 and Al_2O_3/SiO_2 calculated for each slag:

Slags allowed to cool slowly are only feebly hydraulic, even if of proper chemical composition. When used in the manufacture of slag cement, therefore, the slag must be cooled as suddenly as possible. This is effected by bringing the slag, as it issues from the furnace, in contact with a jet or stream of cold water. This sudden cooling "granulates" the slag, i. e., breaks it up into porous particles, and has also two important chemical effects. One is that the slag, if of suitable chemical composition, is rendered strongly hydraulic; the other, that most of the sulphur is removed in the form of hydrogen disulphide. After granulation the slag is dried, usually in rotary driers.

The lime used for mixture with the slag should be low in magnesia, well burned, and carefully slaked. At Chicago, where the Whiting process is used, a small percentage of caustic soda is added to the water used for slaking, the effect being to accelerate the set of the cement. After slaking and drying, the lime is ready for mixture with the granulated and dried slag, which usually has received a preliminary reduction in a crusher, ball mill, Kent mill, or other comparatively coarse reducer. The proportions used will vary from 20 to 40 parts of lime for 100 parts of slag. The mixture and final reduction is usually accomplished, in the American plants, in tube mills. The composition of a number of American and European slag cements is shown in the following table of analyses collected from various sources.

The composition of good slag cements may vary within the following limits: Silica, 22 to 30 per cent.; alumina and iron, 11 to 16 per cent.; lime, 49 to 52 per cent.; magnesia, less than 4 per cent.; sulphur, less than 1½ per cent. It will be noted that the lime content is

lower and the alumina-iron content higher than in a cement of the Portland type. Slag cements also differ from Portland cement in being lower in specific gravity and lighter in color. Normally, they are slower setting than Portland cement, though this defect can be overcome by treatment during manufacture. They are deficient in resistance to mechanical wear, and do not set satisfactorily in dry situations. For use under water or in permanently damp ground, however, they would seem to be of service.

True Portland cements, which must be sharply distinguished from the slag (pozzuolanic) cements discussed in the preceding section of this paper, can be made from mixtures of which one element is blast-furnace slag. In this case the slag is ground, intimately mixed with powdered limestone, and the mixture calcined and reground. Two plants are engaged in the manufacture of Portland cement from slag and limestone in the United States. An analysis of the "Universal" brand of the Illinois Steel Company, a Portland cement made from these materials, is as follows: SiO_2, 23.62 per cent.; Al_2O_3, 8.21 per cent.; Fe_2O_3, 2.71 per cent.; CaO, 61.92 per cent.; MgO, 1.78 per cent.; SO_3, 1.32 per cent.; S, none; loss on ignition, 0.52 per cent.

Cecil von Schwarz, in a paper read before the Iron and Steel Institute of Great Britain, has described in detail German and Belgian practice in the manufacture of Portland cement from blast-furnace slag. (See The Engineering Record of June 2, 1900.) The slag is granulated in order to remove sulphur and to reduce the cost of crushing. The granulated slag is dried and mixed with about an equal amount of limestone. To the mixture is added about 3½ per cent. of powdered slaked lime, and their intimate mixing and reduction are accomplished in ball mills and tube mills. About 8 per cent. of water is added, and the slurry is then made into bricks, which are dried before charging into the kiln. A ring kiln is used, with coke as fuel. The clinker is moistened, stored for six weeks, and reduced in ball and tube mills. Analyses of the limestone, slag, and finished cement follow:

Constituent.	Limestone.	Slag.	Cement.
SiO_2	1.6	30 -35	23.70
Al_2O_3	1.0	10 -14	6.14
Fe_2O_3	...	.....	1.80
FeO	...	0.2- 1.2	.....
MnO	...	3 - 4	.....
$CaCO_3$	97.0	....	.....
CaO	...	46 -49	59.08
MgO	0.5	0.5- 3.5	1.40
SO_3	0.06	0.2- 0.6	1.30
Loss on ignition	...	....	5.70

In England blast-furnace slag has been somewhat largely employed as an adulterant of Portland cement, its color aiding this practice. As commonly carried on, the practice has nothing to recommend it. It should be noted, however, that the addition to a Portland cement of a certain amount of finely ground slag of proper composition should, theoretically, increase the structural value of the product. A "sand cement" made by using slag instead of sand might be made a technical and commercial success, the office of the siliceous slag being to combine with the lime set free during the setting of a Portland cement.

Sleeping cars are to be put on the 173-mile Cleveland-Detroit electric railway.

A Protracted Job of Underpinning.

The five story and basement brick building at No. 51 Exchange Place, New York is adjacent to the west side of the lot on which a tall steel cage building for the Bank of the State of New York is being constructed, as described in The Engineering Record of September 13. The new foundation piers have rectangular pneumatic caissons sunk close to the lot lines, and, as the soil is a very fine sand which will flow through extremely small openings, the excavations endangered the foundations of the old buildings on both sides of the bank lot. Those on the east side were underpinned as described in an article entitled Complicated Underpinning in The Engineering Record of September 27.

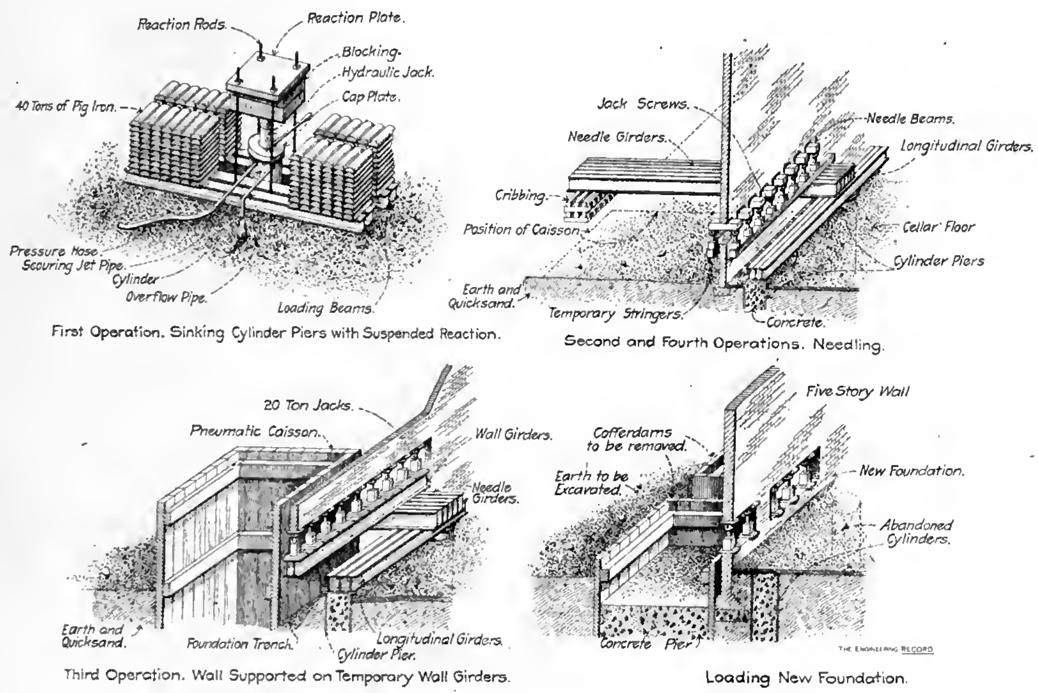
The east wall of the building at No. 51 is about 70 feet high and 100 feet long and has an estimated weight, with its floor load, of about 16,000 pounds per linear foot on the 2x4-foot concrete footing, which was built in a trench excavated only about 6 feet below the curb. This wall required support under its whole length, which might have been positively and permanently afforded by carrying its foundations down to the solid rock in the first place, an operation which could have been advantageously done by sinking cylindrical piers to bed rock, under its center line. This was first done at the Stokes building, New York, as described in The Engineering Record of August 8, 1896, and has since been done in many similar cases in New York, where old foundations were extended to a considerable depth. It was, however, decided to extend the foundations only to about the bottom of the excavation for the bank building, and to seat the footings on the sand and earth at that level.

As the sinking of the caissons so close to the lot line was considered sure to cause some disturbance in the fine wet sand, it was determined in advance not to build the new footings until after the caissons were sunk; and therefore provisions were made to support the wall so as to prevent its settlement from flow of sand while the excavation was in progress and to build the new footings after the caisson work was completed. This system corresponded with the one used for the building on the east side of the bank, but the conditions were somewhat different and caused the details of the work to be modified. Subsequent changes in the plan occasioned further complications in the process, resulting in a very long and elaborate series of operations which have been conducted with great skill and care and have surmounted difficulties of an unusual and serious character.

Both faces of the wall were accessible, but only a very narrow working space was available on the inside, and on the outside most of the ground had to be left unobstructed for the sinking of the 8x15-foot caissons about 6 feet apart and only 2 or 3 inches from the face of the wall. Supports had to be provided on both sides of the wall and as these had to come between the caissons they were about 20 feet apart in the direction of the wall, and as they had to extend beyond the row of caissons they reached at least 10 feet from the outer face of the wall. This necessitated the use of groups of long steel needle girders about 20 feet apart on centers, each group supporting a load of about 320,000 pounds.

Inside building No. 51 operations were restricted to the basement hallway so that the girders could not project more than 5 to 7 feet through the wall, while on the outside they were obliged to extend through the row of caissons and be supported beyond them. This arrangement gave very long span girders with the loads concentrated close to one end. The moments being inversely proportioned to the lever arms gave reactions of about 80,000 pounds at the end of the girder in the bank lot and 240,000 pounds at the end in the cellar. The long ends of the girders were supported in the usual way on timber cribbing which sufficiently distributed their loads on the bottom of the partly excavated pit. The short ends could not be safely supported on the cellar floor so close to the edge of the excavation and it was considered necessary to carry them on piers sunk to rock. The needle girders carried longitudinal girders from which the wall was jacked up to allow the old footings to be removed, compensation to be made for the settlement of the soil, and the new footings to be built and loaded. The weight of the whole wall was transferred from the old foundations to the temporary needle girders in successive sections of about 30 feet, as indicated in the plan of the first and second sections at the street corner of the building.

The first work was to provide for the support of the ends of the needle girders in the cellar of No. 51. This was done, as shown in the sketch of the first operation, by sinking 16-inch steel pipes through the cellar floor to hard pan, a distance of about 40 feet. The pipes were received in short sections and forced down by jacking them against a heavy cast-iron reaction plate from which was suspended a loading platform. As the pipes descended additional sections were screwed on top and the core inside was removed by scouring out the earth and sand with an hydraulic jet through a nozzle on the lower end of a small steel pipe inserted through the upper end of the 16-inch pipe and worked around by hand in the interior. The loosened material was brought up and carried away by the overflow water or was removed finally if necessary by a sand pump, and then the cylinder was filled with concrete and capped with a thick horizontal cast-iron plate at cellar floor level.



First Operation. Sinking Cylinder Piers with Suspended Reaction.

Second and Fourth Operations. Needling.

Third Operation. Wall Supported on Temporary Wall Girders.

Loading New Foundation.

Some Stages of the Work Preliminary to Underpinning.

The loading platform consisted of two pairs of long 15-inch I-beams supported at both ends on timber cross pieces on the cellar floor. The beams were close together in each pair and the pairs were about 2 feet apart. Forty tons of pig iron was piled across each end of the platform and between the piles the pipe sections were set vertically through the middle of the platform. On each side of the pipe cylinder a horizontal transverse pin was arranged to take bearing on the under sides of the beam flanges and engage the loop eye of a 1½-inch vertical suspension rod about 9 feet long with a threaded upper end which projected through a hole in one corner of a cast-iron cap plate about 28 inches square and 3 inches thick. On each rod there was a nut screwed up tight against the plate on both the upper and under side, thus holding it in position against a vertical force in either direction. When a jack was inserted and operated between the top of the cylinder and the cap it developed reaction in the vertical rods, by which, at the limit, the whole load was lifted from the floor and suspended from the top of the cylinder, sufficing with the scouring from the 60-pound jet and ¾-inch nozzle to gradually sink it until another section could be added, and so on. In each cylinder the first section of pipe was 10 feet long and was started in a hole cut through the concrete floor and dug as deep as possible in the open; the remaining sections had uniform lengths of 5½ feet and all were ⅜-inch thick.

At the commencement of the work the pipe sections were coupled together with outside screwed sleeves 6 inches long. These were found to offer a great resistance to sinking and in one case where they were used it took eight men 12 days to sink the cylinder 12 feet. To diminish the resistance the edges of the sleeve were beveled, as shown in the sectional view, and thin wooden lagging of exactly the same thickness as the sleeve was carefully fitted under its edges and around the pipe and secured with thin sheet metal bands. This reduced the friction but it cost $5 a length and caused considerable delay in fitting it on after the pipe sections were coupled up. Finally inside sleeves were substituted for the outside ones, and, the ends of the pipe sections being fitted to make accurate butt joints, a smooth continuous exterior surface was secured which offered much less resistance to sinking. At first the cylinder was driven by a screw jack; but when this was replaced by an eighty-ton hydraulic jack, two men were able to sink it twice as fast as eight had done with the screw. A line of eight cylinders was sunk about 16 feet apart and 3 feet from the wall which was to be underpinned. They were filled with concrete and capped with thick iron plates on which were seated three longitudinal lines of 15-inch I-beams to receive the inner ends of the transverse needle girders, which were inserted through the wall in holes made just above the footing.

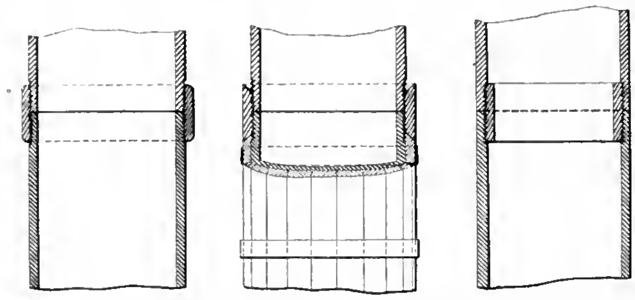
A horizontal row of holes about 14 inches square and 3 feet apart was made 4 feet above the tops of the needle girders and short 12x12-inch needle beams were inserted in them and supported at both ends on jack screws on longitudinal temporary stringers close to the faces of the wall which were carried by the needle girders and on temporary intermediate blocking as shown at the left of the plan and in the sketch of the second operation. The jacks were operated to lift the wall about 1/8 inch as noted by a level set up in the street and reading on marks made on the face of the wall and on a permanent bench mark established across the street. All the old masonry below the needle beams was removed and a pair of 24-inch 100-pound I-beams resting on the needle girders were inserted in the plane of the wall between the jackscrews. Single 20-ton jackscrews were placed in engagement between the top of the I-beams and the bottom of the brickwork, between the needle beams, as shown in this sketch of the third operation and were turned up to release the needle beams. As the latter were removed their places were filled by pairs of 5-ton jackscrews between the 20-ton screws and the whole weight of the wall was thus transferred to the pair of 24-inch girders in its plane which acted as like a lintel and transferred an estimated load of nearly 500,000 pounds to the needle girders, which in turn carried it to their four points of support close inside the wall and a considerable distance outside of it.

Another set of holes for needle girders and needle beams was pierced in the adjacent section of the wall and it was supported in the same manner and the process was repeated until the whole of the wall was carried on jackscrews in its plane or under the ends of short needle beams. The 24-inch girders were set alongside the wall before the needle beams were put in service, and when 24-inch I-beams were not available, two 12-inch I-beams, one on top of the other, were substituted. The first group of needle girders had to be placed about 10 feet from the front of the building so as to come between the adjacent caissons, and this left a portion of the wall near the corner which was supported on the cantilever ends of the 24-inch longitudinal girders projecting 8 feet beyond the center of support on the needle girders.

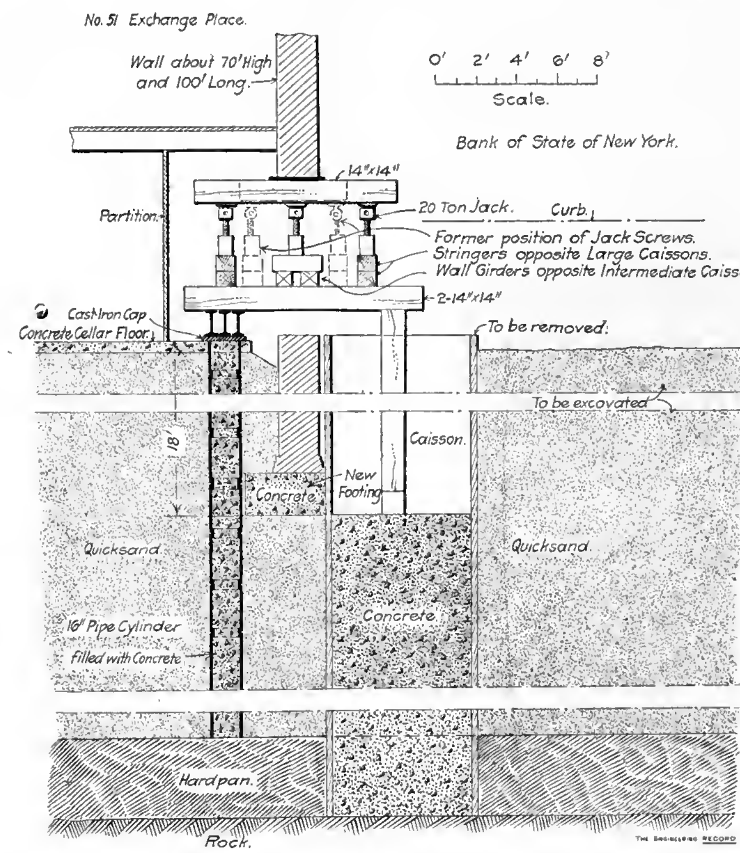
The first floor and basement doors in the street front extend to the side wall and very much weaken its bond with the front wall. Cast iron columns are built into the brickwork on both sides of the doors, and these were reinforced by cover plates bolted on over their lower splices and by a transverse horizontal brace across the feet of the columns, which held them rigidly when they were lifted from their bases and the latter were temporarily removed so that the lower parts of the columns were suspended. The front wall at the corner was supported on a vertical shore engaging the lintel over the first story door and bearing on two jackscrews seated in about the middle of a pair of long 15-inch I-beams which were carried at one end on the needle girders and at the other end on blocking on the sidewalk. The front of the wall was braced by inclined shores, reaching up to the second story and having their feet set on jackscrews chained to the needle girders.

Greased vertical planks were fastened to the face of the wall and served as guide strips, in contact with which the caissons were sunk between the needle girders, as shown in the sketch of the third operation. After the caissons were sunk the needle beams and temporary stringers were replaced as in the second operation, and the load of the wall was transferred to them and the 24-inch wall girders were released and removed to allow the new footing to be built up close to the under side of the old wall at the level of the needle beams. It was found when excavation was commenced in the bank lot, inside the row of wall caissons, that the fine sand flowed in rapidly from the site of the adjacent building through the spaces between the caissons. It was therefore determined to close the spaces by intermediate caissons, which, with the original caissons, form a continuous wall enclosing the side of the bank lot.

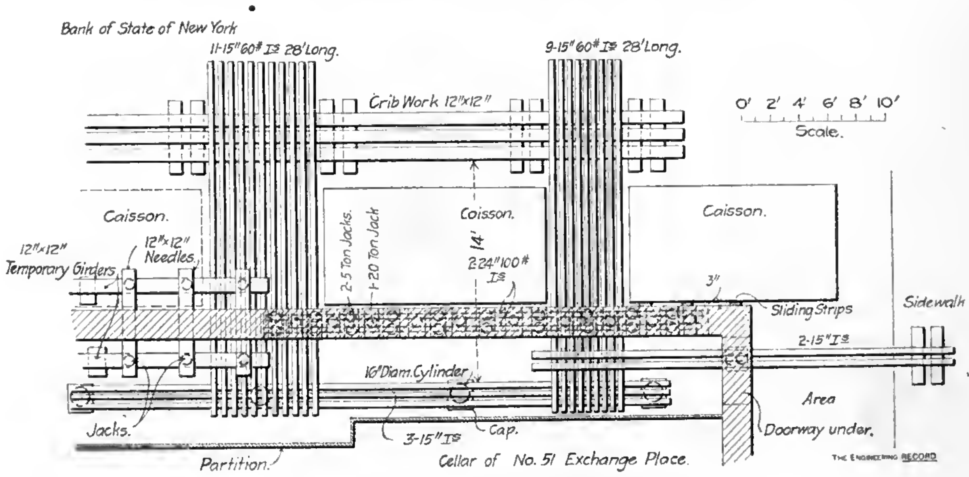
As these caissons occupy the space in which the needle girders were originally set the latter had to be removed after each of the temporary longitudinal stringers which they carried had been replaced by a pair of 14x14-inch timbers, one on top of the other, set close to them outside, and supported on pairs of 14x14-inch horizontal transverse needle girders close together side by side. These are 12 or 14 feet long, from 8 to 12 feet apart on centers, and are supported inside the building on the pipe cylinders, and outside on pairs of vertical 14x14-inch posts set on the concrete in the



Cylinder Pier Joints.



Support of Wall on Second Set of Needle-Beams.



First Section of Underpinning Beams, Girders and Cylinders.

caissons. The temporary stringers are about 7 feet apart on centers and carry lines of 20-ton jackscrews from 2½ to 3½ feet apart which support the ends of 14x14-inch 10-foot needle beams.

Between the rows of jackscrews pairs of longitudinal 14x14-inch timbers about 10 feet long were set side by side in the plane of the wall, so as to span the spaces originally left between the caissons where the steel needle girders had been and the jackscrews were set on them to receive the weight of the wall directly. The adjacent needle beams were thus released and removed and the temporary stringers were cut out between the caissons, leaving clear spaces to sink the intermediate small caissons. After these are completed the center lines of jackscrews and timbers opposite them will be replaced by the needle beams and outside stringers, the new foundations will be built with their footings carried down to a total depth of 24 feet below the curb, equal to the greatest depth of the bank excavation, the wall will be built up close to the lower part of the old wall and the weight of the latter will be transferred to it by a center line of jackscrews engaging old and new brickwork, the needle beams will be withdrawn and the jackscrews operated to lift the building as fast as the pressure causes the new footings to settle. When the settlement entirely ceases the brickwork will be completed and wedges driven and grouted between the old and new parts and the jackscrews gradually removed as the spaces are bricked up.

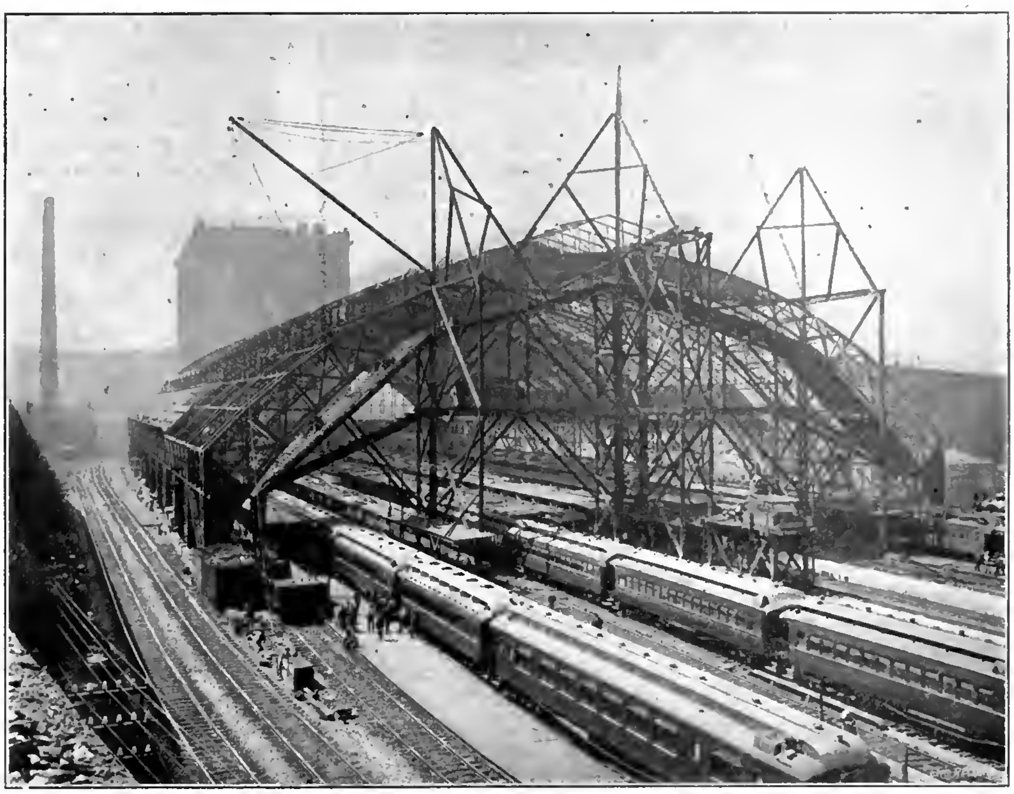
When completed the work will have been accomplished in eight operations: First, sinking the pipe cylinders; second, carrying the wall on needle beams; third, shifting the wall to center line of jacks and 24-inch girders; fourth, transferring the wall to longer, new needle beams; fifth, transferring portions of the wall to center lines of jackscrews and longitudinal girders opposite the intermediate caissons; sixth, building new footings; seventh, transferring the weight of the wall to the new footings and releasing and removing the needle beams; eighth, closing the joint between old and new brickwork and removing the jackscrews. This complex and protracted series of operations involved lifting six times a wall about 100 feet long and 70 feet high, weighing 1,600,000 pounds, which had to be supported at the extremities of long beams while every inch of the face was left free and clear for deep excavations alongside, and had to be preserved from distortion, cracking and other injury. The interior of the building had to be unobstructed and any interruption of tenants or business avoided, and finally the wall had to be constantly watched and adjusted to compensate for the continual undermining of the fine sand under its foundation. This involved vigilance for many weeks, and a system of periodical measurements and records, together with frequent lifting of portions of the wall to maintain its position. For some time the jackscrews had to be turned up daily and their total extension amounted to about 2½ inches, thus indicating the amount which the wall really settled and was lifted. The successful accomplishment of this complicated and prolonged series of delicate and dangerous operations, which were of an unusual nature and involved such critical conditions and heavy loads, reflects great credit on the courage, skill and ability with which they were conducted. The work was executed by the George A. Fuller Company, general contractors for the Bank of the State of New York, and was in charge of Mr. A. E. Riendau, who planned and supervised the method and details.

The pipe cylinders in the cellar of No. 51 Exchange Place were sunk under the direction of Mr. C. C. Lovejoy, who accomplished the work in the very narrow space available without obstructing any other part of the building or interfering with the tenants. If the same cylinders had been sunk under the center line of the wall so as to serve for the underpinning and carry the weight directly to bed rock once for all, as has been illustrated in The Engineering Record in descriptions of the Empire, Gillender, Corn Exchange, Stock Exchange, Queen's buildings and others of similar character which have been built in New York under conditions similar to those at the Bank of the State of New York, the work would have been greatly simplified and shortened and its cost diminished. Instead of the eight operations described only two would have been required—sinking the cylinders and transferring the weight of the wall to permanent bearing on them. The cylinders would have been sunk much more rapidly and less expensively by jacking them down from the under side of the wall itself, and thus avoiding the labor and delay of the less efficient artificial reaction which was secured by the suspended reaction platform. No transfers of loading would have been required, and no settlement would have occurred. The support of the wall would never have been diminished nor the loads on the soil increased. There would have been no obstructions necessary on either side of the wall, and no restrictions to the excavation or caisson sinking. The foundations would have been permanently established on solid rock without unnecessary work, and the cylinders would be in permanent service instead of being abandoned in the cellar. The cost of labor and materials for the entire work would probably have been less than for the first operation described above.

Losses by Forest Fires in the United States are very great, according to a bulletin issued by the Bureau of Forestry at Washington. In an average year 60 persons perish, \$25,000,000 of real property is destroyed, 10,724,000 acres of timber land burned over, and young growth estimated at \$75,000,000 killed.

The Erection of the Pennsylvania R. R. Train Shed, Pittsburg.

The new Pennsylvania Railroad train shed at Pittsburg is a 260x555-foot building 110 feet in extreme height, which was described in The Engineering Record of August 23. The walls and roof have a steel framework with twelve pairs of three-hinge arch trusses of 255-foot span on centers of end pins. The pairs of trusses are 49½ feet apart on centers and the trusses are 9 feet apart in the pairs, the two trusses of each pair being transversely braced together to form a single rib with considerable independent lateral stiffness, and the ribs being braced together with longitudinal struts and diagonals. The trusses have vertical end posts about 37 feet high from the top of the pier to the hip; between the hips the top chord is uniformly curved and the bottom chord is correspondingly curved, but to a smaller radius so as to increase the depth from about 7 feet at the crown to about 16½ feet at the hips. The trusses are built in symmetrical halves connected by a 5-inch pin at the crown and bearing on 5¾-inch end pins through pedestals like bridge shoes which rest at one end on expansion rollers, and at the other end on fixed bed plates.



Erecting Arch Trusses of Pittsburg Train Shed with Traveling Falsework.

The train shed occupies nearly the same position as the old train shed and the difficulties of erection were considerably increased by the necessity of maintaining uninterrupted service for 261 regular passenger trains and transporting 100,000 passengers daily at the same time that the shed site was raised several feet to the new grade and the old depot building was removed and a temporary one constructed. The construction of the new 137x225-foot head house, fourteen stories high, was not exactly a part of the train shed erection, but was so nearly associated with it that it may be considered as influencing that problem.

The west end of the old train shed was first removed and an 89x200-foot temporary wooden house was built on its site and equipped with offices, waiting rooms, restaurant, kitchen, etc., to accommodate the passengers while the new structures were being built. The pipes in the building were connected to the city water main and sewer by double swinging folding arms connected with four elbows so that they opened and closed without springing and allowed the building to be raised as the ground underneath was filled in to the higher new grades. The walls of the old depot were braced by 6x4-inch longitudinal and transverse horizontal timbers at the second story level and a track being laid through the center of the building the materials were carried off on it as fast as torn down. After it was completely removed the foundation excavations were made in sheeted pits and circular concrete piers with conical, extended footings were built in them. The piers rested with a pressure of 4 tons per square foot on a gravel bed 50 feet thick, and were capped with cast iron pedestals which transmitted a pressure of 20 tons per square foot to the concrete.

Under and around the train shed the grade was raised as much as 13 feet in places over an area of about 10 acres by filling in about 100,000 cubic yards of slate, clay and rock excavated from a cut in the hillside which later accommodated several new tracks. The grading was done while about 350 regular trains a day passed over the twenty tracks, and no obstruction or delay to traffic was occasioned by it. The tracks were quickly jacked up about a foot at once, singly, at times when the trains were least frequent. They were temporarily supported on stones while a dirt car was run alongside and ballast tamped under to the required height.

The head house was designed and erected very much like a steel cage office building and after its erection and the completion of the grading the erection of the train shed was accomplished without interrupting the numerous trains constantly passing over the tracks below which were parallel to its axis and covered its site. The tracks were mostly as close as possible together, in pairs with spaces for narrow passenger platforms between the pairs. The platforms were covered with temporary low wooden roofs and very little space was left for the falsework or for handling materials at ground level.

The erection of the train shed was substantially the erection of twelve double bents of roof trusses of about 255 feet span and 87 feet clear height, and was accomplished from a movable falsework with derricks fixed on it, which traveled the entire length of the building. The falsework was about 230 feet long, extending across all but the two outside tracks in the shed (on which two it was supported) and was about 14 feet wide, in the direction of the longitudinal axis of the shed, and about 82 feet high above the rail base in the center. It consisted of a working platform having four inclined planes supported just below the lower chords of the arch trusses by six vertical bents transverse to its length and parallel to the longitudinal axis of the train shed. Each bent was made with two 12x12-inch vertical posts braced together with caps, sills, intermediate horizontal struts and 6x12-inch X-braces in the panels between the horizontal members. The bents were braced together by the working platform and by horizontal and inclined timbers parallel to the planes of the roof trusses.

Each bent was set on double flanged wheels arranged tandem and with the exception of the outside bents ran on rails spiked to 8x14-inch stringers laid on line of platforms so as not to interfere with the use of the tracks. The falsework thus formed a single stable structure which spanned nearly the full width of the train shed and moved under the completed roof trusses from one end of it to the other. The middle two trestle bents, about 10 feet apart, were connected at the top by a horizontal section of the working platform, and were braced together with four panels of longitudinal horizontal struts and vertical X-braces to form a tower. The sills were extended about 40 feet beyond the face of this tower, on the advancing side, to engage with four more 12x12-inch vertical posts in the planes of the trestle bents. These posts were also transversely and longitudinally braced by horizontal struts and X-braces and formed an independent tower with its top extending above the top of the other tower to the level of the upper chord of the arch truss and supporting, at the outer face, the foot of one stiff-leg of a derrick with a 45-foot mast and a 10-ton, 75-foot boom. This tower was thoroughly braced to the main falsework and formed a buttress greatly increasing its moment of stability and adding to its resistance to any forces which might tend to overturn it when being advanced on its narrow base.

The lowest transverse struts, parallel to the planes of the arch roof trusses, were about 12 feet above the tracks so as to clear the passenger platforms and shelters and allow passengers to pass freely through the bases of the towers to arriving and departing trains. The falsework trestle bents next to the center tower on each side were about 60 feet away from it and were connected to it by 12x15-inch horizontal struts attached to their vertical posts at about the middle points. These struts were supported near their centers by long 10x10-inch kneebraces reaching nearly to the feet of the vertical posts but clearing all trains on the intermediate tracks. Similar kneebraces from the ends of these struts supported the centers of the inclined girder-struts which connected the tops of the trestle bents and carried the working platforms.

Two more 12x12-inch vertical posts about 85 feet high and 40 feet apart were braced together in the plane of each of these two trestle bents and fastened and braced securely to the falsework. The top of the outside post in each case was at the level of the adjacent top chord of the roof truss and supported, at the outer end, the foot of one stiff leg of a boom derrick. These derricks were similar to the one in the center of the falsework, and like it had one leg in the plane of the front face of the falsework and secured to it. The remaining two trestle bents, at the ends of the falsework, were about 12 feet high and were not braced in the planes of the arch trusses. Their tops were braced by struts running to the middles of the adjacent bents and carrying a foot walk to the platform which was built there and supported a house used for office and tools. The engine which operated the south derrick was on a platform moved along the south track immediately west of the traveler. The engine for the center and north derricks was located on a traveling platform in advance of the center tower-buttress.

The inclined girder-struts connecting the tops of the trestle bents were chords of four approximately equal segments of the bottom chord of the arch truss. They were pairs of 12x18-inch timbers connected by transverse floorbeams from 6 inches to 11 feet apart to accommodate iron connections on their upper sides. The floorbeams were covered with 3-inch longitudinal planks laid close together and, on the steeper portions of the platform, were provided with cleats to improve the foothold. All connections of the falsework timbers were made with ¾-inch bolts except for some of the lighter braces which were spiked on and all the vertical post splices were made with scabs, like bridge falsework. The falsework contained about 43,400 feet of timber b. m. and with the derricks had an estimated weight of eighty-eight tons.

The falsework was erected with gin poles at the end of the train shed nearest the head house. The arch trusses were received in twelve sections each, delivered on cars running on the regular passenger tracks to the base of the falsework and then hoisted into place and assembled by the three derrick booms which commanded more than a panel of the roof. The pedestals on the south side of the shed are built on solid rock and are only seven feet deep, enough to form an anchorage. The north pedestals are built of concrete founded on a bed of gravel 30 feet below the level of the track and are capped with sandstone. The shoes were in two pieces, as shown in The Engineering Record of Aug. 23.

The bottoms of the shoes on the south side were first set in place and anchored. The bottom chords, formed of 12-inch I beams in 30-foot lengths, were then put in position by drawing them through boxes under the tracks from north to south in the following manner: Two sections of chord were riveted together and pulled through until the north end was clear of the north pedestal. A third section was then riveted on and the whole pulled 30 feet further, when the process was repeated until the whole chord was in position. Both sections of the north shoe and the upper sections of the south shoe were then placed in position and the pins driven home; after which the boxes in which the chords lay were filled with bituminous concrete. This work was completed during the erection of the traveler.

The haunches or vertical end sections of a pair of trusses reaching from the top of the shoe to the hip joint U30-U22, and weighing about 5½ tons each, were then set in position by the side derricks and held until they were bolted to the upper section of the shoe. When they were released, the top of the haunch rested on the traveler. The remaining sections of the truss, about 30 feet long and from 7 to 17 feet wide, were lifted by the derrick booms and set on blocking and camber wedges on the working platform. Both trusses of a pair were assembled simultaneously from both pedestals and were made stable by bolting up the lateral and sway braces in the narrow panel before the sections were released by the derrick booms. The crown hinge pins were driven without trouble as the camber wedges were slacked off to bring the pin holes to match. The purlins, longitudinal struts and intermediate rafters were hoisted and assembled by the main derrick booms, and the falsework was moved out from under the arch rib and advanced one panel length to position for the erection of the next pair of trusses, and so on.

The falsework moved on 16-inch wheels on six lines of rails, and was pulled forward about 50 feet in two or three minutes actual moving time by its three hoisting engines winding up on tackles anchored in the ground in advance of the center and two side bents of falsework trestle. The falsework was not guyed, but the end and adjacent trestle bents were after each movement temporarily braced by inclined shores and the whole structure was jacked up from its wheel bearings when in use. The first arch rib was guyed in both directions by steel cables tightened by tackles anchored to secure fastenings in the ground on both sides of the trusses and care was taken to keep the lateral braces between the trusses well connected during erection. Temporary diagonal bracing of adjustable wire ropes and timber struts were put in the panels between the vertical end posts of the trusses as the work progressed to stiffen it until the sheathing was put on. The lantern and monitor frames were erected with small derricks and gin poles after the falsework had been removed to the next panel in advance.

There were from eight to fifteen gangs of riveters who usually kept the work finished within about one panel of the assemblers. Most of the rivets were driven by pneumatic hammers, with flexible pipes to a 2½-inch main laid from end to end of the falsework and connected to a compressor plant and receiver stationed on a flat car on the north track of the shed just west of the traveler and moved along with it. The total erection force comprised from 75 to 130 men and the best record was the assembling and swinging of a 100-ton pair of arch trusses in 2½ days.

The train shed was designed in the engineering department of the Pennsylvania Railroad Company, Mr. W. H. Brown, chief engineer, under the direction of Mr. W. A. Pratt, now assistant to the chief engineer. The structural steel, weighing about 2,350 tons, was furnished by the Edgemoor branch of the American Bridge Company and was erected by the Pennsylvania Railroad Company workmen in charge of Mr. A. Braun, under direction of Mr. George C. Clarke, assistant engineer in charge of construction.

American Floor System.

arranged so much alike that both can be described together. The object of the tests is stated in the official reports as follows: "To record the effect of the continuous heat of a wood fire below the floor system, averaging not less than 1,700 degrees Fahrenheit for not less than four hours, the filling between the two beams being loaded with a distributed load of 150 pounds per square foot of its area and all carried by such filling; the fire being extinguished at the end of the test with a stream of water directed against the bottom of the platform and discharged through a 1⅛-inch nozzle under 60 pounds pressure for five minutes; flooding the top of the platform with water under low pressure, and then again applying the stream of water through the nozzle under 60 pounds pressure to the bottom of the platform for five minutes."

Each series of tests was made in a brick building constructed for the purpose, the roof forming the flooring system under investigation. The buildings were approximately 14 feet square internally, 10 feet high, and had grates 2½ feet above the ground level on which the fires were made. There was a large door for placing the wood in the house, and various doors and chimneys for draft.

One of the flooring systems tested was that of the American Fireproof Construction Co., of New York. The roof framing in this case was formed of 10-inch 15-pound channels on the walls, with knee-braces of similar channels at the corners, the braces starting from points 4 feet from each corner. The main supports for the roof were a pair of parallel 10-inch 45-pound I beams spaced 5½ feet apart. These beams and the wall channels parallel to them were connected by two rows of ¾-inch tie rods. The steel reinforcement for the concrete was furnished by 1x1-inch T bars laid on the lower flanges of the roof beams as shown in the illustration. The 5½-inch bottom layer of concrete was placed on April 4; it was mixed in the proportion of one part Portland cement, one part sand and six parts of steam ashes. On April 10 the 6½-inch upper bed was laid; this was a mixture of one part Portland cement and fifteen parts of steam ashes. Two days later the centering was taken down and the ceiling of the center bay plastered with half an inch of Acme plaster.

The other floor system tested was that of the White Fireproof Construction Co., of New York. The framing was practically the same as that just described save that the main floorbeams were 12-inch 31½-pound I beams spaced 6 feet 1-inch on centers. The reinforcement was formed of 9/16-inch round tension rods spaced 12 inches apart and laid on the lower flanges of the beams as shown in the illustration. These were wired to three ½-inch rods, placed parallel with the floorbeams to serve as spacers for the tension rods. The bottom 5½-inch concrete bed was mixed in the proportion of one part Portland cement, two parts sand and five parts steam ashes, and was placed on April 4. On April 17 the top filling of 8 inches of concrete mixed in the proportion of one part Portland cement to ten parts of cinders was put in place, and the centering removed. The ceiling was plastered on May 2 with half an inch of Rockwall plaster.

The fuel used for each test was pine and mixed cord wood, the fire being accelerated at the start with kerosene. The floor was loaded to 150 pounds per square foot with brick. The temperature of the fire was measured with a LeChatelier pyrometer. The deflections were observed at nine stations with a Y level. The results obtained are given in the accompanying table, the temperatures being in Fahrenheit degrees and the deflections in inches at the centers of the beams and arch.

The condition of the American arch after the fire test is described as follows in the official report: "The plaster applied to ceiling was destroyed by the fire and water. Two T bars of the center arch had their bottom flanges exposed, otherwise the floor was intact with only a small amount of the principal concrete filling washed down by the water. The concrete showed a very considerable amount of coherence. The beam protection was effective."

peratures are expressed in Fahrenheit degrees, and the deflections in inches at the centers of the beams and arch.

The official report of the condition of the arch after the fire test reads as follows: "The plaster applied to the ceiling (principal arch) was all destroyed by the fire and water. Two of the 9/16-inch round rods were exposed by the water. The beam protection was in good condition, as was generally the entire arch with the exception of the exposing of the two rods mentioned."

The loading test was made on May 10 and the unloading test on May 12, and the results, in connection with those of the fire test, were so favorable as to lead Mr. Ewing to recommend allowing the construction to be used in the Borough.

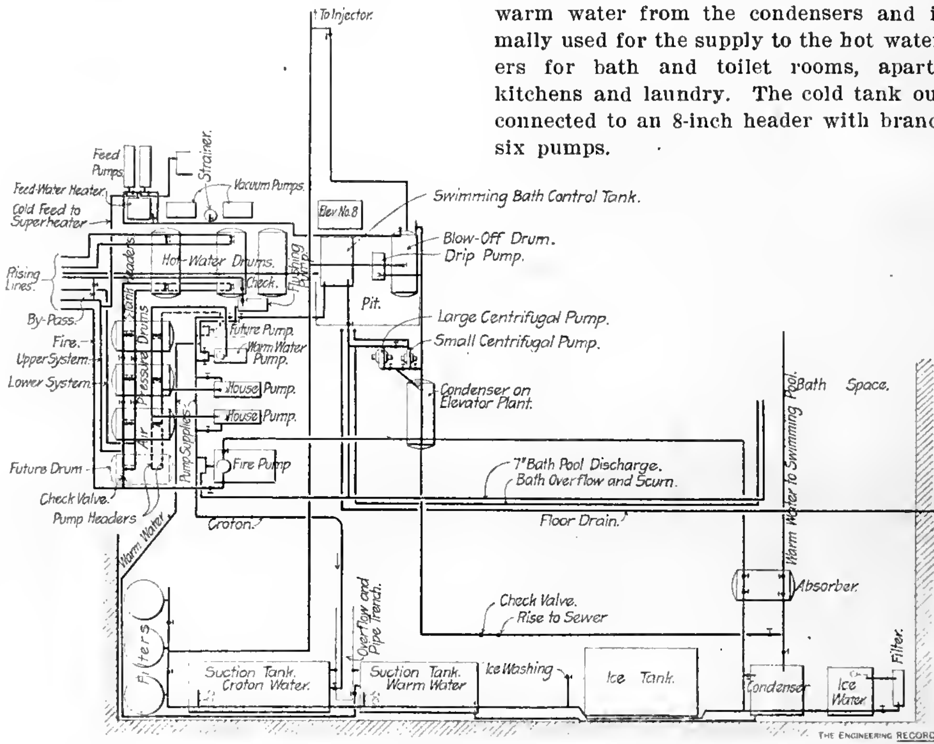
Water Supply Systems in the Ansonia Apartment Hotel.

The Ansonia, at Broadway and 73rd and 74th Streets, New York, is a very large seventeen story, steel and iron building with housekeeping and family hotel apartments for about 1,300 tenants. It is equipped for public and private service and provides from the general installation for individual tenants. It contains three hundred and fifty-five suites of two to thirteen rooms each, every one of which has a toilet room and from one to three private bath rooms. There are 112 private kitchens, 112 butler's pantries, two public dining rooms, a restaurant, a grill room, two large kitchens, a very large laundry, public toilet rooms, Turkish, Russian and swimming baths, a barber shop, reception and assembly rooms for general use, and

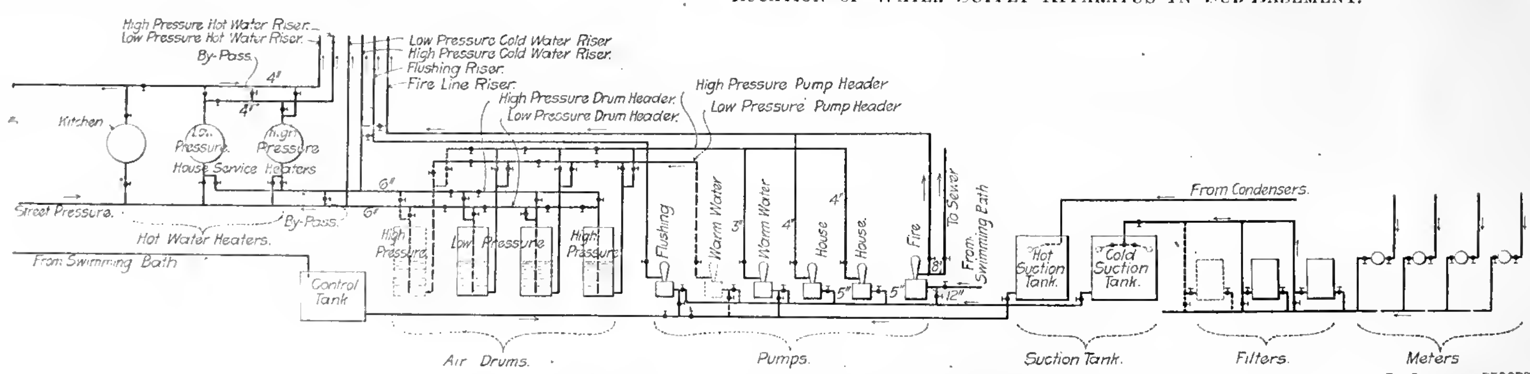
elevator pumps might be properly considered as a tenth system. All water above the first story is supplied under direct pump pressure, with intermediate air cushion drums. The drums and pumps are arranged in double pairs, one set for the supply above the ninth floor and one set for the supply between the first and ninth floors. The upper system is supplied from the top downwards, and the lower from the bottom upwards, thus avoiding excessive pressures and expensive pumping which would be occasioned by the great height of the building if the lower fixtures were under full pressure head. Nearly all the apparatus is located in the sub-basement, and the general plan is to make all the pumps and other apparatus interchangeable and

tor pumps, to the refrigerating plant condensers and to the swimming bath. Between the filters and the suction tank there are direct branches to the boiler feed, to the kitchens and laundry and to the drinking water filter.

There are two 17,500-gallon rectangular suction tanks built of steel plates and angles, mounted on brick piers and covered with wooden tops having locked trap doors. They are painted outside with a shop coat of carbonizing compound and two finishing coats of lead color, and inside with two coats of white enamel. Each is filled through two 4-inch Ludlow valves with cylinder floats and has a 6-inch overflow and a 6-inch outlet. One tank receives cold water directly from the filters, which is used for the cold house supply and the other receives warm water from the condensers and is normally used for the supply to the hot water heaters for bath and toilet rooms, apartments, kitchens and laundry. The cold tank outlet is connected to an 8-inch header with branches to six pumps.



LOCATION OF WATER SUPPLY APPARATUS IN SUB-BASEMENT.



GENERAL ARRANGEMENT OF APPARATUS, CONVENTIONALLY SHOWN.

studios, stores, offices and a bank for rental. It is estimated that there may be about 1,700 people in the building at once and that about 280,000 gallons of water a day, or 84,000,000 gallons a year, will be required for all purposes. This involves a very elaborate water supply and drainage system, which is said to be the largest ever installed under one roof, including as it does 322,000 feet of pipes and over 2,000 fixtures.

The distribution of water may be divided into nine separate systems: high-pressure cold water, high-pressure hot water, low-pressure cold water and low-pressure hot water, all for house service, street pressure cold water and hot water for the basement service, water for the flushing service, water for the fire service, and cold drinking water. Besides these, the street pressure supplies to steam boiler feed, to the refrigerating plant, the hose washing cocks and for the public baths and to the

cross connected so that any given element may be cut out without interfering with the service, can reinforce another similar element, or can be used for any of the systems at will.

Water from the street mains on three sides of the building is received through four 4-inch and one 3-inch lead pipe connections, all of which are controlled by gate valves accessible through manholes with iron sidewalk covers. Each supply has a fish trap and a full size Worthington meter with gate valves each side. All are connected to a main which can discharge into the cold water suction tank directly or through three by-passed Loomis-Manning filters. These filters each have a capacity of 100 gallons a minute under the ordinary street pressure of 30 pounds, and one used for the flushing system has a capacity of 60 gallons a minute under a head of 17 feet. Between the meters and the filters the supply main has direct branches to the fire pump, to the eleva-

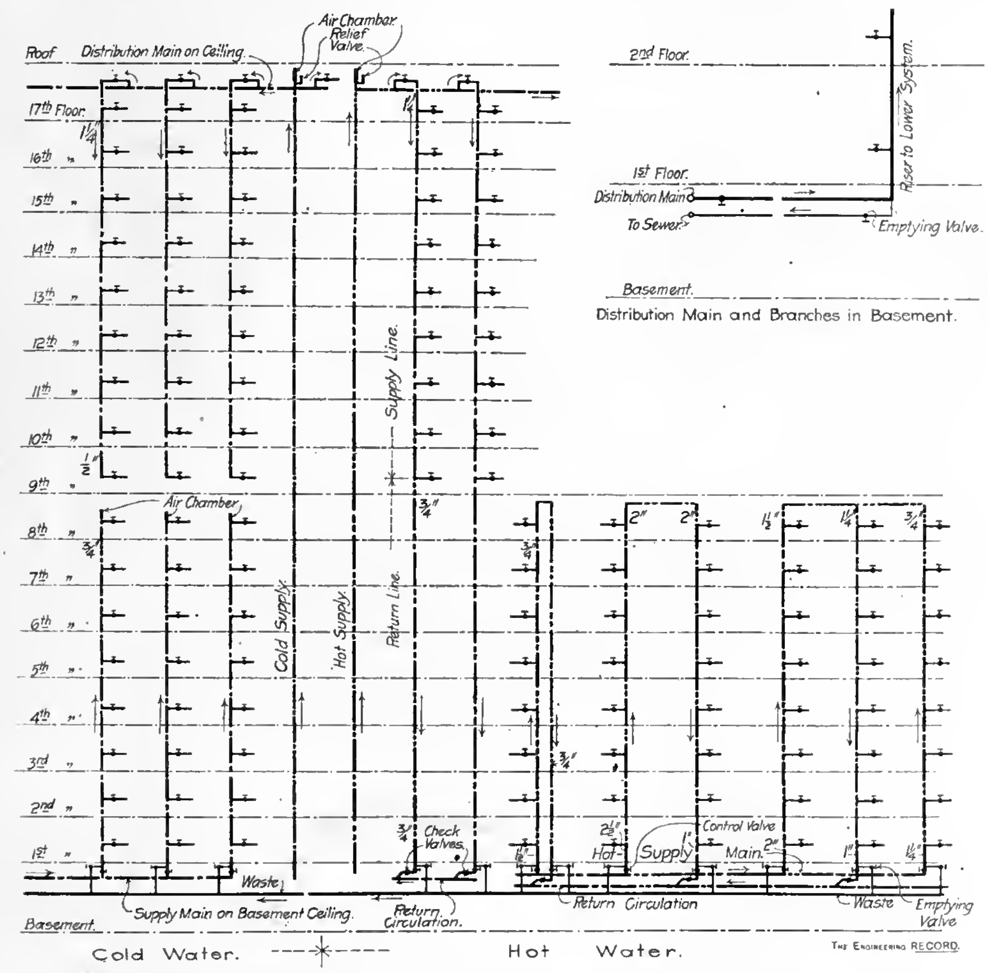
There is an 18x12x10-inch Worthington Underwriter's fire pump with 8-inch suction and 7-inch discharge and a capacity of 1,000 gallons per minute; two compound Davidson direct-acting 9x12-inch cold water high or low pressure pumps, two single Davidson direct acting 12x7x12-inch hot, high or low pressure pumps and a 7½x4½x10-inch Worthington duplex pump for the flushing system. The two hot water pumps are connected to the suction pipe from the warm water tank and the fire pump has a connection to the swimming pool. The flushing pump can draw either from the cold water or warm water suction tanks but is normally supplied from an overflow tank which regulates the level of the water in the swimming bath. The fire pump has two discharges, one to the swimming pool and the other to the fire lines which may be cross-connected to the high-pressure house service cold water system. The flushing pump is also connected to the latter system. All the pumps are automatically controlled by Foster pump regulators. The house pumps are not directly cross connected, but deliver into high and low pressure headers which are valved so that either pump can be put under either pressure.

From both headers supplies are run to each of the air drums, two of which are normally under high and two under low pressure. Each drum is a vertical steel cylinder 5½ feet in diameter and 9 feet high, made with ⅝-inch thick sides and domed heads and supported on iron legs. Each has a 6-inch inlet and outlet and is provided with a 2-inch adjustable relief valve, with extension to the bottom of the drum to act by water pressure, and 8-inch dial Ashcroft pressure gauge indexed to 200 pounds per square inch, a 1½-inch air inlet with valve and swing check, a 1½-inch emptying pipe, a ⅜-inch governor pipe extended to the bottom and connected to the pump controllers so as to regulate the pumps and automatically maintain the pressure in the drums with a variation of not more than 5 pounds. Each drum has a manhole and a mud hole and was shop tested to 220 pounds per square inch, and tested to 150 pounds after its connections were completed. The outlet of each drum is connected to a low-pressure and to a high-pressure header, one valve being always closed so that two of the drums work normally under high and two under low pressure. The headers are cross-connected and have branches to the hot water heaters and to the house distribution lines and risers. By this system the pumps and air drums are usually used in pairs, each pair operating with high or low pressure and with warm or cold water.

There are four distribution mains on the basement ceiling, one for street pressure cold, and one for low pressure hot and separate circulation for the basment fixtures, one for low pump pressure hot, and one for low pump pressure cold to riser lines supplying fixtures between the basement and ninth stories. The hot and cold risers are taken from the ends of branches connected to the upper sides of the distribution mains as shown in the detail sketch.

The low pressure cold water risers are vertical pipes from 2 inches to ½ inch in diameter, diminishing upwards and terminating with an air chamber and air valve in the eighth story. There is no circulation through them except what is caused by the flow of water to the different outlets. The pressure is regulated by the pump governor and is such as to give about 50 pounds at the lowest and 10 pounds at the highest fixtures. The hot water risers in this system are like the cold water risers except that instead of terminating with air chambers at the upper ends they make loops there and return with parallel branches to the basement. In most cases this branch is ¾-inch in diameter and serves simply for the return circulation, but in some cases it is 1½ inches in diameter at the top, reducing to ¾ inch at the bottom, and supplies fixtures. In a third arrangement two hot water risers have a horizontal connection in the eighth story which is connected to a return circulation pipe common to both risers. The feet of all return circulation pipes have horizontal branches in which check valves are set to prevent any reverse flow up the pipes. These are connected to return mains delivering in the usual way to the bottoms of the heaters. The feet of both the flow and return pipes have controlling and emptying valves.

All the hot and cold water for the fixtures above the eighth story is delivered through two main risers, distributed through horizontal belt mains in the seventeenth story, and supplied downwards through vertical pipes diminishing in size as they pass the fixtures in successive stories. The cold water pipes terminate in the ninth story and are emptied through their lowest fixtures. The hot water pipes are reduced to ¾ inch diameter below the ninth story fixtures and thence continue to the basement as return circulation pipes without outlets. At their feet they are connected to a horizontal return main as in the low pressure system. The pressure at the seventeenth story fixtures is about ten, and at the ninth story fixtures about fifty pounds.



Water Supply Systems for Upper Stories Exclusive of Flushing System.

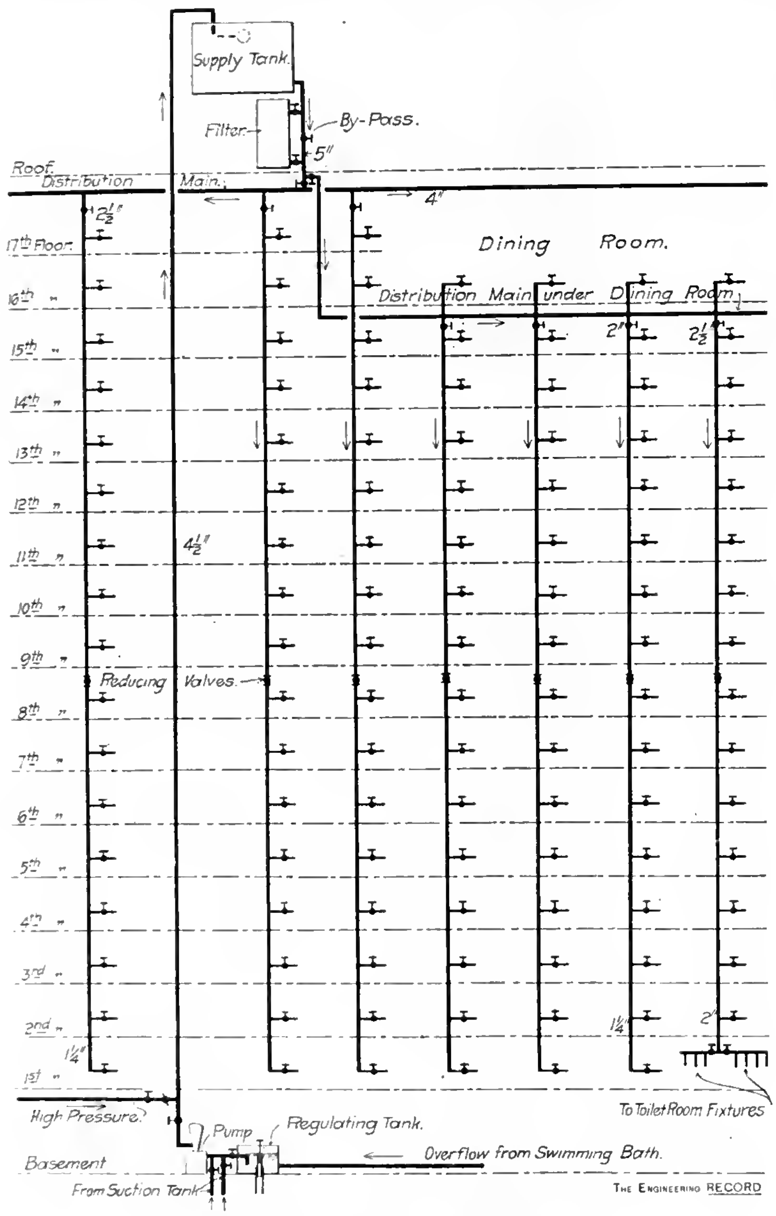
The hot water heaters are 5-foot horizontal cylinders, 12 feet long, made of ½ inch steel plates and tested to 175 pounds. Each has a capacity of 1,800 gallons and contains an 80-foot coil of 2-inch brass steam pipe. Each has a safety valve, a 4-inch inlet and outlet, and a Kiely & Mueller automatic regulating device to maintain a constant temperature in the water which is generally received from the warm water tank at a temperature of about 100 degrees. All the heaters are insulated and are by-passed so that their service is interchangeable.

The swimming baths receive a constant liberal supply of warm water which has passed through the condensers of the refrigerating plant. It overflows into a regulating tank that serves as the normal supply for the flushing system, and is thus used three times so as to effect an important reduction in the water bills. If the flushing supply is in excess of the requirements the surplus is wasted from the regulating tank and is pumped into the sewer; if it is deficient the lack is made up by warm water from the condensers, by cooler water from the absorber, or by cold water direct from the street supply.

The flushing pump delivers through ball cocks into a 21,000 gallon double tank above the roof, and when the tank is full the closing of the cocks develops pressure in the discharge pipe which operates the automatic Ford regulator, shuts off steam and stops the pump. From the roof tank the water passes through a Loomis-Manning filter to a distributing main in the seventeenth story and thence through lateral branches to vertical pipes supplying all the toilet fixtures in the house. The water is so clean that it would not be offensive if not filtered and it may be by-passed around the filter if necessary. A large dining room occupies a part of the sixteenth and seventeenth stories, and as risers cannot pass through it from the general distribution main a special main is run under it in the fifteenth story to supply the lines to the lower fixtures and has also connections upward to the sixteenth story fixtures. There is a Ford pressure reducing valve set in each vertical line of the flushing system at the eighth story to prevent excessive pressures on the lower story fixtures. The lines terminate at groups of fixtures in the first and second stories and some of them are connected at the foot with headers from which connections are made to a number of fixtures.

The fire pump suctions are connected to the cold water storage tank and to the swimming bath, and its 7-inch discharge is connected to 6-inch mains running in opposite directions on the basement ceiling and having four connections to Siamese unions at the sidewalk and four 5-inch stand pipes in the centers of the main corridors besides fourteen outlets with hose lines to various points in the cellar, basement and first floor. Two of the stand pipes have nineteen and two of them have eighteen outlets, with from 50 to 160 feet of hose for each, making a total of eighty-four outlets and 8,810 feet of hose. All of the stand pipes are run full size to the roof and two of them are extended above it. The different hose lines command every portion of every floor and will throw jets across to the opposite sides of all the courts. The fire system has a connection with the high-pressure house supply riser, with a swinging check valve so that all the water in the pressure tanks can be made instantly available, and when the street fire engines are connected to the Siamese unions their pulsation will be absorbed by the air cushions in the pressure drums. The four house pumps with a united capacity of 1,000 gallons a minute are fitted with check valves in their discharge pipes and are cross-connected so that they can supplement the fire pump, and it is also possible to use all the water in the hot and cold suction tanks and in the swimming bath for fire purposes.

The drinking water supply is drawn from the high pressure house main, refiltered and passed through a tank in which there is a coil through which brine from the refrigerating plant is circulated at a low temperature. This cools the water to about 40 degrees and maintains that temperature while it is circulated by duplicate compound 8x12x5x10-inch Knowles pumps to supply a faucet in every housekeeping suite of rooms and a number of public drinking fountains in different stories. The refrigerating plant is installed in the basement and supplied, as previously stated, with filtered water under streeet pressure. It is used for freezing 5 tons a day of ice in cans, and also for cooling a large quantity of brine which, by special compound duplicate Knowles pumps is circulated through coils in the refrigerators in the different apartments and kitchens and cools them without the direct use of ice. Small freezing tanks are, however, arranged in the private refrigerators by which limited quantities of ice may be made, or wine cooled for table use as required.



WATER SUPPLY FOR FLUSHING SYSTEM.

All water pipes are of galvanized iron with extra heavy fittings, tested to 200 pounds pressure at the shop before shipment and to 150 pounds after being put in place. In the three lower stories the high-pressure pipes are made extra thick. Except the exposed connections to fixtures, which are nickel plated, all water pipes are painted and are generally accessibly located in shafts or wall chases. All dead ends terminate with air chambers, and all pipes are pitched to emptying valves by which they can be drained separately without interfering with other portions of the system. The supply to each suite of apartments and to each fixture in the suite, is controlled by independent valves so as to be cut out without stopping the supply to any other part of the system, and the general supplies for the suites, for the kitchens and laundry, for the baths, and for the public service are all separate and independent.

The covering of pipes and apparatus includes both exposed and concealed work and is intended not only to prevent condensation of atmospheric moisture on the surface of the pipes and tanks but to prevent also the cold water from being warmed and the hot water from being cooled by radiation. All hot and cold water pipes, mains and fittings except the short branches to the toilets or fixtures, are covered 1 inch thick with the Philip Carey Company's double felting, canvas wrapped, banded with iron and painted two coats of asbestos paint. The pressure drums and filters are covered with wire net and 1½-inch slabs of Keasbey's magnesia, wired on, and plastered with two coats of hard plaster, finished smooth and painted.

The system is controlled by 80 check valves up to 10 inches in diameter, and by 9,143 other valves exclusive of automatic float and pressure regulating valves. There are 1,848 Jenkins gate valves 2 inches in diameter and larger with iron bodies, composition seats and iron hand wheels, 2,626 1 to 2-inch globe valves with composition bodies and hand wheels, 3,896 globe and 773 lock shields, nickel plated valves at fixtures. All cellar and basement valves have numbered tags corresponding to a chart which shows what service they control. All the supply lines except those for the high-pressure service in the stories above the ninth floor are controlled by basement valves, but these are not concentrated on distribution drums as is sometimes the case. Each separate riser has a control and emptying valve at the foot where it is connected to the ceiling branch from the distribution main.

Mr. Paul E. Duboy was the architect, and Mr. Reginald Pelham Bolton, M. E., consulting engineer, designed and supervised the installation of the water supply and sanitary systems. Milton Schnaier & Company were the contractors for the above described work.

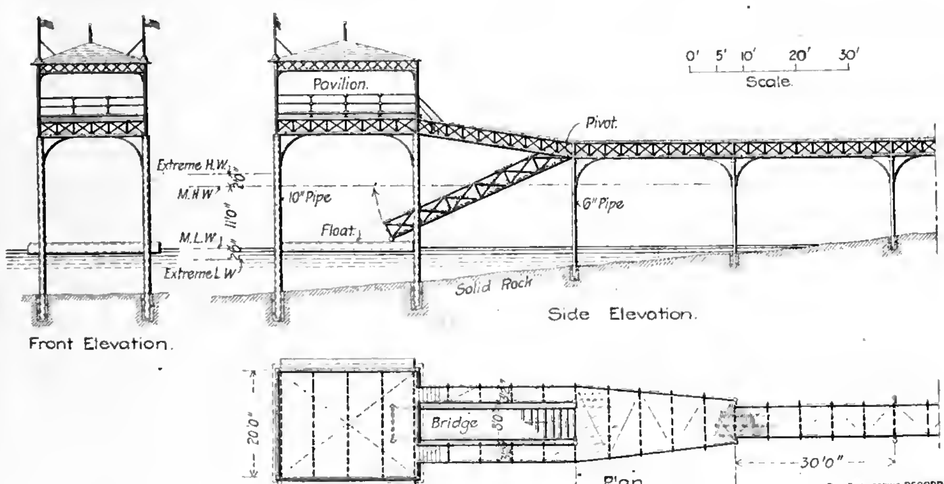
A Seaside Resort Steel Pier and Pavilion.

At Bar Harbor, Me., an elevated steel pavilion has been built about 240 feet from the shore and connected with the promenade from the Mount Desert Reading Room by a light steel pier having a pivoted bridge to the floating landing stage under the pavilion. The pier has six trestle bents, which, together with the masonry abutment and retaining wall at the shore end and the pavilion columns support six regular 30-foot spans and two special spans of the pier floor. Each bent consists of two vertical cast iron columns 6 inches in diameter, ¾ inch thick and 8 feet apart, the tops of which are braced longitudinally by curved knee braces to the lower flanges of the longitudinal girders. Transversely they are connected by cross girders and by stiff angle bracing extending down from 7 feet on the shorter columns to 14 feet on the longer ones.

The columns are from 10 to 22 feet long with their tops in a horizontal plane about 5 feet above mean high water. They are capped by horizontal steel plates riveted to collars or split sleeves made of 9-inch vertical plates bent to semicircles fitting the column and bolted together tightly around it through their projecting flanges. The horizontal struts consist of a pair of 3x2½-inch angles riveted together back to back with connection web plates at the ends which have flange angles tap-bolted to the columns. These plates receive the diagonal struts which are single 3x3-inch angles with top connection plates riveted to the collars which secure the caps. The knee braces are pairs of 3x2½-inch angles curved to quadrants of a circle of about 5 feet radius. A plate is riveted to the bottom of their wide flange and is curved to fit the column to which it is attached by stud bolts. Each cross girder is a pair of 6-inch channels latticed together, 5 inches apart and seated on the cap plates of the columns to which they are secured by rivets through their lower flanges.

About 18 inches from each end each cross girder supports the abutting ends of two riveted trusses 3½ feet deep and 5¾ feet apart on centers. These trusses are formed as indicated in the elevation, with verticals and diagonals and are braced sideways from the top chords to the ends of the floorbeams. The chords are pairs of 3x2½-inch angles back to back, the verticals are single angles and the diagonals are alternately single $2\frac{1}{2}$x2-inch angles and 3x$\frac{1}{4}$-inch flat bars. The trusses serve for hand rails and their top chords are covered by half round wooden strips finished smooth and secured by screws on the under side. At every alternate panel of the truss there is an intermediate floorbeam which consists of a 5x3-inch angle $8\frac{1}{2}$ feet long which is riveted across the flanges of the bottom chord and has sway braces from its ends to the top chords of the trusses. The lower chords are braced laterally by zig-zag $2\frac{1}{2}$x$2\frac{1}{2}$-inch angles, one in each panel between floorbeams. Four lines of 3x4-inch longitudinal joists are laid across the floorbeams and carry the 2x6-inch transverse floor boards, laid with open joints.

In the second span from the pavilion the floor is widened to nearly 14 feet to give room in the span next to the pavilion for a center descending walk to the float and an ascending walk on each side to the pavilion floor. The descending walk is a bridge 6 feet wide which has two trusses similar to those in the regular spans, but somewhat longer and having longer panels. The upper end is pivoted to the floorbeam and the lower end has roller bearings on a floating platform which serves for the boat landing at all stages of the tide. The platform is a few inches narrower than the pavilion floor so as to



Steel Pier, Pavilion and Pivoted Bridge.

clear the four pavilion columns, and extend a little beyond each pair. It is connected to the columns by sleeves which enclose and slide freely on them, allowing the float to rise and fall with the tide between the columns as guides. The four columns supporting the pavilion are 10-inch steel tubes, $\frac{1}{2}$ inch thick. The pavilion platform and steps leading to same are enclosed by a gas pipe railing, and the pavilion has a tin roof supported on 10x3-inch wooden hip rafters.

The pier is built on solid rock, which slopes uniformly about 1: 15 from the shore. A temporary wooden trestle was built on the center line of the pier and supported an artesian well-drilling machine which bored 8 and 12-inch holes 4 or 5 feet deep to receive the cast iron columns. A light derrick traveled on the trestle and set the columns in place where they were filled with Portland cement concrete and Portland cement mortar filled in any spaces in the holes outside the columns. The foundations are thus made very secure and the structure has proved rigid and able to resist the wind and waves. The total weight of metal work is about 25 tons and it was erected in a few days after the foundation holes were bored.

The pier and pavilion were designed and built by Messrs. Snare & Triest, contracting engineers, New York.

Trade Publications.

Conveyors for handling coal and ashes are described in the October bulletin of the Steel Cable Engineering Co., 92 State St., Boston. It builds a gravity bucket conveyor, driven by a continuous chain, the cross-bars of which are located vertically over the edges of the buckets, so as to constitute a lap between them. Its pan and bucket conveyor includes a moving trough of interlapping pans on the lower or filling run of the bucket chain. Some of the conveyors are arranged for steel cable driving. Various methods of application to power, coaling and other plants are illustrated.

Fuel oil equipments is the title of a pamphlet issued by the Petroleum Iron Works Co., Washington, Pa., devoted to the use of oil as a fuel in steam plants. As generally installed, the apparatus consists of a storage tank, a pump, a vertical pipe into which the pump discharges, the pipe having an overflow and used as a constant pressure regulator, and the burners to which the oil passes from the regulator. The burners use steam for atomizing the oil, and for sending it into the furnace in a whirling jet. The recommended form of settling in its application to different classes of boilers is shown.

Readers of the article on the plant of the Cambridge Electric Light Co., in this issue will find in a pamphlet prepared by Mr. Frank B. Gilbreth, 176 Federal St., Boston, inventor of the portable gravity concrete mixer, some nine views of the method of building the foundations for that plant. The interesting feature of the work is that the mixer is carried by derrick from place to place, allowing the concrete to be dumped from the mixer directly into the place where wanted.

The Whitehall Portland Cement Co., 712 Reading Terminal, Philadelphia, has published in one cover a description of its site and raw materials at Cementon, Pa., an historical sketch of the manufacture of cement, the report of Major Marshall, Major Leech and Captain Crosby, Corps of Engineers, U. S. A., on the testing of cement, and some valuable information concerning the use of cement in freezing weather, cement in sidewalks and the composition of concrete for various uses, together with numerous tests of the Whitehall cement. The booklet is interspersed with views of the Cementon works and of buildings, bridges and dams in which the cement has been used.

The Western Electric Co., Chicago, has issued catalogue No. 3020, which is devoted chiefly to direct-connected exhaust fans and steel-plate blower equipment. The exhaust fan motor outfits are designed for 110, 220 and 500 volts. Suggestions are given regarding the proper setting of fans, including a method of mounting fans in places where unusually high temperatures are encountered.

The Christensen Engineering Co., Milwaukee, Wis., has published three beautifully printed and illustrated catalogues. One describes the "Ceco" electrical machinery, including direct-current motors, direct-current generators from 25 to 1,000 kilowatts capacity, alternators of 75 to 1,500 kilowatts capacity, transformers and dynamic interrupters for transformer protection. Another, No. 53, is devoted to straight air-brake equipments, with independent motor compressor, for electric cars; this is a detailed account of the various parts of the system and their operation and is accompanied by instructions for installing and maintenance and by plates of typical application. Publication No. 54 is a description of the works of the company where the air brakes are made and contains a long list of patrons, with a large number of illustrations of railways equipped by it.

The Green traveling link grates are the subject of Catalogue C of the Green Engineering Co., Western Union Building, Chicago. The illustrations show the latest improvements in its chain grate, and the booklet will be found of value alone from a list of bituminous coals of the States of Ohio, Pennsylvania, Illinois, Indiana and Kentucky, giving by counties the output of the mines, the heat value of the coal and its proximate analysis.

The Page concrete mixer consists of a rectangular box with filler blocks in the corners, the box being revolved by a central shaft inclined at about 45 degrees. The top of the box is open and being inclined, allows for ready charging; a door in the side of the box is the discharging outlet. Page & Shnable, Security Building, Chicago, show its operation in a circular they are distributing.

A 47-page catalogue, $9\frac{3}{4}$x$12\frac{1}{4}$ inches, in size, has been issued by the Gurney Heater Manufacturing Co., 74 Franklin St., Boston, covering the complete range of steam and hot-water boilers, radiators and heating accessories which it manufactures. Full page illustrations of the boilers and radiators are given, and the book includes corresponding tables of dimensions, capacities and prices.

The Eugene Dietzgen Co., 181 Monroe St., Chicago, is distributing a circular describing a new electric blue-printing machine. This consists of a cylindrical printing frame composed of two heavy curved plates of glass, which is carried by a base which also holds the printing frame and which supports the arc lamp and an automatic lamp driving gear. The cylindrical frame revolves on trunnions, so that it can be swung into a horizontal position for loading. When the lamp reaches the end of its downward travel, it is automatically reversed and returns quickly to the original position.

The Buffalo Forge Co., Buffalo, N. Y., has issued a booklet illustrating its horizontal center and side-crank, horizontal tandem compound, vertical center-crank and compound and marine types of steam engines. It has also prepared a booklet on mechanical induced draft in which are shown a number of different types of induced draft fans.

The G. Drouvé Co., Bridgeport, Conn., has prepared two circulars, one describing the Lovell window and shutter operating device and the other a portable stove it makes for burning either hard coal or coke and designed primarily for temporary warming, as in a building undergoing erection. The Lovell device is said to be capable of operating a line of sash 500 feet long from one station, if desired, and is adaptable to any kind of sash.

The Pittsburg Blue Print Co., Park Building, Pittsburg, has prepared an illustrated catalogue of its electric blue-printing machines. These are furnished in both upright and tilting types, the latter allowing the cylinder about which the sensitized paper and tracings are wrapped to be held in a horizontal position while loading and placed in the vertical position for printing. This type is intended especially for making copies of small tracings which can thus be easily handled.

The 1902-1903 catalogue of the Dunning boilers and tanks has been issued by the New York Central Iron Works Co., Geneva, N. Y. It is a book of 56 pages, containing a detailed description of the boilers, illustrations and tables of the different types and a large number of testimonial letters. The descriptive matter is liberally indented with catch heads so that specific features may be studied at a glance.

The Watertown Engine Co., Watertown, N. Y., is distributing a folder giving a concise statement of the points of the Watertown four-valve steam engine, and showing a section through the cylinder and valves.

The Robins belt conveyor as applied to mining operations, where it is designed to handle as much as 1,200 tons of tailings and waste per hour, is described in a circular published by the Robins Conveying Belt Co., Park Row Building, New York City. An interesting illustrated account is given of the operations at the plant of the Gold Pan Engineering & Mine Supply Co., at Breckenridge, Colo.

Personal and Obituary Notes.

Mr. E. G. Barrow has been elected city engineer of Hamilton, Ont.

Mr. E. R. Gayler and Mr. E. H. Brownell have been appointed civil engineers in the U. S. Navy.

Mr. W. H. Daub has been transferred to the engineering department of the Chicago, Rock Island & Pacific Railway.

Mr. Clifford B. Moore and Mr. Abraham U. Whitson have been appointed transitmen for the Aqueduct Commission of New York City.

Mr. Bernard Haentzchel has been appointed superintendent on the Mines and Metallurgy building for the Louisiana Purchase Exposition at St. Louis.

Mr. D. M. Quay has resigned his position with the George A. Fuller Co., to become president of the Mannados Enginnering Co., Townsend Building, New York.

Mr. W. E. Belknap, M. Am. Soc. C. E., has resigned his position as assistant engineer in the Department of Docks and Ferries of New York City to accept a business engagement.

Mr. Justin Burns, Assoc. M. Am. Soc. C. E., has resigned his position with the Rapid Transit Railroad Commission of New York to take charge of the construction of some 700 miles of railroad in China.

Mr. M. M. Richey, Jr., acting general superintendent of the Central Railroad of New Jersey, has been appointed superintendent of the Birmingham division of the Southern Railway, at Birmingham, Ala., to succeed Mr. C. S. Hayden, resigned.

Mr. Samuel M. Gray, M. Am. Soc. C. E., has been engaged by the Citizens' Association of Paterson, N. J., to make a preliminary examination of the Passaic River, in connection with an investigation of the best system for the disposal of sewage of that city.

The officers of the Jamestown, Va., exposition to be held in 1907 to commemorate the foundation of the Anglo-Saxon civilization in the Western Hemisphere are Fitzhugh Lee, president; Gen. D. Lowenberg, Norfolk, Va., director; Gwynn F. Shepperd, Norfolk, secretary.

Mr. Arthur J. Cox, who is a partner of Mr. Charles P. Chase in the engineering business conducted by the Iowa Engineering Co. at Clinton, Ia., has returned from a fourteen months' trip in Europe, where he has made an investigation of sewerage and sewage disposal systems of France, Germany and England.

The National Association of Railway Superintendents of Bridges and Buildings has elected the following officers: B. F. Pickering, Seabomville, N. H., president; C. C. Mallard, Algiers, La.; A. Shane, A. Zimmerman, Denver; A. Moritzheimer, Milwaukee, vice-presidents; S. F. Patterson, Concord, N. H., secretary; N. W. Thompson, Ft. Wayne, Ind., treasurer.

Col. Washington A. Roebling has submitted to an operation in a New York hospital in the effort to regain the physical comfort which he has not enjoyed during the thirty years that have elapsed since he contracted caisson fever in the construction of the New York and Brooklyn bridge. His physicians are reported as saying that there is every reason that he will be restored to health.

Frederick Tudor, a well-known engineer and contractor in the heating and ventilating business, died October 28 at Lincoln, Mass., aged 57 years. He was graduated from Harvard in 1867, and first began as a civil engineer in the construction of the White Mountain extension of the Boston & Maine Railroad. He was best known as the inventor of the Tudor system of steam heating, patented about 1885.

Mr. James Corbett has been appointed superintendent of the Chicago & Erie division of the Erie Railroad, at Huntington, Ind., and is succeeded as superintendent of the Susquehanna & Tioga divisions at Elmira, N. Y., by Mr. T. H. Pindell, who resigns the superintendency of the Greenwood Lake division, with headquarters at Jersey City. He will be succeeded by Mr. J. C. Tucker, of Rochester, and Mr. Tucker by Mr. E. T. Resiler.

The following nominations for officers for the ensuing year of the American Society of Mechanical Engineers have been made by the nominating committee: President, William Sellers, Philadelphia; treasurer, F. H. Stillman, New York City; vice-presidents, F. H. Daniels, Worcester; James Christie, Philadelphia, and John R. Freeman, Providence; managers, R. C. McKinney, New York City; S. S. Webber, Trenton, and Newell Sanders, Chattanooga.

Prof. Sidney H. Short, one of the first experimenters of electric street traction, died of appendicitis in London the early part of last week. He was between 43 and 44 years of age. In the early eighties he became professor of chemistry of the University of Denver, where he began experimenting in electricity, building an underground high-tension road, in which the cars were operated in series. Although this system proved a failure it led him into a field in which he made a great number of inventions. He established the Short Electric Railway of Columbus and was at one time connected with the Walker Electric Co., of Cleveland.

The Recovery of Bridge Steel from the bed of the Des Moines River near Des Moines, Iowa, is being carried on by the American Bridge Company with the aid of divers. Two hundred thousand pounds of steel that had been placed on the falsework of the eastern span of the Chicago Great Western bridge were dropped into the river during a flood in July.

The Wearing Surfaces of Highway bridge floors were made the subject matter of a recent report by a committee of the Association of Railway Superintendents of Bridges and Buildings. In response to a set of questions sent out by the committee, a number of interesting replies were received. Mr. J. B. Sheldon, superintendent of bridges and buildings of the New York, New Haven & Hartford R. R., reports that with a traffic that will wear out 3-inch plank in two years Trinidad asphalt will last from six to seven years, and states it to be his experience that where a large volume of business is done, requiring a strong bridge with a wearing surface of asphalt or granite blocks, the paving will last enough longer to more than pay for the extra cost of a bridge strong enough to carry the added weight and the expense of an under floor to support the paving. Mr. A. S. Markley, superintendent of bridges and buildings of the Chicago & Eastern Illinois R. R., reports that white oak plank 4 inches thick, laid on 6-inch string pieces 2 feet apart, will last from six to eight years, excepting where traffic is very heavy, and in such cases the life of the plank does not exceed three years. It will always wear out before it decays.

The Extensive Use of Automobiles in France is strongly impressed upon one by the great number met on the streets of Paris and the roads of its environs, writes a correspondent of The Engineering Record. Every form and size, from the autocycle, with two wheels, for one passenger, to the heavy waggonette, for several passengers and heavy baggage, is common. The machines are operated at high speed generally, and driven with great skill. Their durability and reliability are shown, in a way, by the number of "dead" machines hauled along, and the number halted for repairs by the wayside; but few dead machines are seen in the streets of Paris. Probably the best place in the country, and the most favorable time, to observe the automobiles is the ten miles of road between Paris and Versailles, on a day that the fountains play at Versailles. This occurs but once or twice a month during the summer, and on a very few especial occasions. The flow of water lasts only a fraction of an hour, but the spectacle is magnificent and attracts a vast crowd. After the exhibition, late in the afternoon, the road to Paris is traveled by a large number of the spectators. While driving from Versailles to Paris, starting just before the completion of the flow, between fifty and sixty automobiles passed by the coach. Nearly all were four-wheeled and carried four passengers or more. Four or five were electric; the others were of the internal-combustion, oil-burning type. The road is excellent, but has several long inclines of considerable grade. The speed up grade was anywhere from four to twelve miles an hour for different machines. Down grade all ran at high speed, many at thirty, and some apparently at nearly forty, miles an hour. Although the driveway is generally narrow, three vehicles abreast filling it, there was no evidence of accidents or of near approach to any. Upon coming near Paris a considerable number of the machines were seen halted for repairs. From twenty to twenty-five per cent. of the machines on the home trip were stopped and undergoing repairs, nearly all with the machinery uncovered. This is a very large proportion. Possibly it is due to the high speed that every *chauffeur* seemed bent on making down grade.

CONTRACTING NEWS

OF SPECIAL INTEREST TO

CONTRACTORS, BUILDERS, ENGINEERS AND MANUFACTURERS

OF ENGINEERING AND BUILDING SUPPLIES.

For Proposals see page xv, xvii, xviii and xxvii.

WATER.

Washington, D. C.—A. G. Lakenaw, Ch. Clk., Engr. Dept., D. C., writes that the contract for furnishing 135 tons of cast-iron specials (bids opened Oct. 18) has been let to the Dimmick Pipe Co., Birmingham, Ala., at $90 per ton; total, $12,150.

New York, N. Y.—Bids will be received Nov. 6, by Robert Grier Monroe, Comr. of Water Supply, Gas and Electricity, for furnishing single and double nozzle case hydrants, lead-lined iron pipe, unions, elbows and couplings.

Meadville, Pa.—City Engr. W. A. Doane writes that contracts are about to be let for a 150-H.-P. boiler and 20-in. suction pipe for the new water supply.

Penngrove, N. J.—Bids will be received Nov. 12 by the Mayor and Council for the erection of water works, consisting of two 500,000-gal. compound duplex steam pumps, 1 boiler feed pump, 1 heater, two 75-H.-P. boilers, steam and water fitting, 1 steel smokestack; tower and tank 18x32 ft., 90 ft. above foundations; brick power house; 4 miles of cast-iron pipe, 10 to 4 in. diameters; 29 valves and 41 fire hydrants. John P. Leap, Chmn. Water Com.

Hammonton, N. J.—Bids will be received Nov. 7 by the Water Comrs. for furnishing and erecting two 500,000-gal. compound duplex steam pumps, two 100-H.-P. boilers, heater and boiler feed pump, and steam fitting. J. L. O'Donnell, Secy.

Long Island City, N. Y.—The Dept. of Water, Gas & Electricity is said to be planning water main extensions in the Boro. of Queens. Over 8½ miles of pipe will be required, including a relief main in Astoria, 2 miles in length and 12, 14 and 16 ins. in diameter.

Brooklyn, N. Y.—Ch. Engr. N. P. Lewis, of the Bd. of Estimate has reported in favor of the construction of pipe galleries in the subway in Fulton St., between Boerum Pl. and Flatbush Ave.; estimated cost, $150,000. Also in the subway on Broadway, between Ann and Morris Sts.; estimated cost, $250,000.

McKeesport, Pa.—The Water Comrs. are considering plans for the improvement of the water supply. Supt. T. H. Verner recommends the installation of a filtering plant and the construction of another reservoir.

Allentown, Pa.—The City Council has adopted a resolution requesting the Mayor to communicate with an expert engineer to visit this city and recommend a plan to bring in and store the water from Schantz's Spring.

Bloomsburg, Pa.—Robt. Snodgrass, of Harrisburg, W. H. Dale and Victor Koch, of Scranton, with others, have incorporated the Town Water Co. and applied for a charter. Their purpose is said to be to supply water to all the towns between Bloomsburg and Berwick.

Timberville, Va.—Local press reports state that this town is about to install a gravity system of water works.

Barnesville, Ga.—The City Council has decided to purchase a duplicate pump for the electric light and water works department.

Savannah, Ga.—Hal H. Bacon, Chmn. of Water Com., writes that the following bids were opened Oct. 25 for a Corliss cross-compound duplex compressor air pump, condenser, pipes, valves and necessary fittings for connecting a duplicate compressor: Bacon Air-Lift Co., New York, $15,415; Pneumatic Eng. Co., $13,987.

Xenia, O.—Consulting Engr. O. H. Jewell and Walter Wagner, of Chicago, having been engaged by the Water Works Trus. to make plans and specifications for a water purification plant for this city, have reported recommending that a filtration plant having a daily capacity of 10,000,000 gals. be located on the banks of Mahoning River opposite the present city water works; they also recommend the installation of meters. For the low-service pumping station two 10,000,000-gal. pumps, each, connected to a vertical compound condensing engine, are recommended.

Findlay, O.—City Engr. John W. S. Riegle writes that all bids recently received for contemplated water main extension have been rejected and new bids will be asked soon upon 20-in. cast iron pipe and upon 24-in. vitrified pipe. Proposed line, 10.6 miles long.

Prophetstown, Ill.—Village Clk. B. J. Loomis writes that on Oct. 21 it was voted to construct water works, and that the village is now ready to receive plans and specifications for works.

Lake Park, Minn.—Bonds to the amount of $15,000 are to be voted for water works, sewerage and electric lighting, according to press reports.

Duluth, Minn.—At the recent election it was voted to purchase the West Duluth water plant for $140,000.

Ottumwa, Ia.—The Supreme Court has decided that the city may levy a tax for the municipal ownership of water works, and press reports state that the city will construct a plant to cost $400,000, the contract for which has been let.

West Bay City, Mich.—The Water Comrs. are reported to have decided to install the meter system.

Victoria, Tex.—The Refugio Land & Irrigation Co. has been incorporated, with a capital of $600,000 to construct, maintain and operate dams, ditches, etc., for irrigation purposes The incorporators are: J. C. Dilworth, of Gonzales, Tex.; J. C. McDowell, of the Guffey Oil Co., Pittsburg, Pa.; Preston Austin, of Victoria, and others.

Webster Grove, Mo.—Bids are wanted Nov. 3 for furnishing fire hydrants, valves, meters, etc., and laying 47,485 ft. of 4 to 12-in. cast iron water pipe. Wm. H. Bryan, Consulting Engr., Lincoln Trust Bldg., St. Louis. Edw. S. Hart, Chmn. Com. on Water Supply.

New Orleans, La.—According to local press reports Wellman Bradford, of Crowley, La., has organized an irrigation company, to construct a canal at a probable cost of $1,000,000; total length of canal about 64 miles, in the parishes of St. Landry, Acadia and Calcasiu, with the Mississippi River as the source of supply. Geo. Thompson, of New York City, is said to be Pres. of the Co.

St. Louis, Mo.—The Bd. of Pub. Improv. has rejected all plans of the World's Fair engineers for laying wrought-iron water mains on the Fair Grounds and referred the matter to the Water Comr., with the suggestion that he notify the World's Fair engineers to use cast-iron pipe.

Eagle Lake, Tex.—A franchise is said to have been granted for the establishment of water works and an electric light plant.

El Paso, Tex.—The Olio & Fruitland Canal Co., of Olio, New Mex., has been incorporated. Capital stock, $50,000. The company is organized to construct canals and irrigation ditches from the San Juan River. The term of existence is fifty years. The directors are Henry T. Stotworthy, J. G. Biggs, Walter O. Ashcroft John R. Young and others.

Kenton, Wash.—It is stated that bids are wanted Nov. 10 for $4,900 water-works bonds. Geo. W. Custer, Clk.

Maybell, Colo.—Wm. P. Wagner, Gen. Mgr. of the Maybell Canal Co., writes that bids are desired for work contemplated by said company. Estimated cost, $30,000. J. Q. Ellis, Pres.; Wm. Taylor, Engr.-in-Charge.

Santa Fe, New Mex.—Important improvements are to be made in the water works of this city, which are owned by the Santa Fe Water & Light Co. Edgar L. Street, Advising Engr., 44 Wall St., New York City.

Antonito, Colo.—Chas. Brickinstein, Surveyor of Customs; Zeph Charles Felt, of Denver, and Albert R. Smith, of Manassa, are said to be interested in a scheme to build dams to store water on the Mogote and Elk Creek reservoir sites, west of Antonito, on Conejos River, said reservoirs to hold from 50,000 to 75,000 acre ft. of water each. J. C. Ulrich, of Denver, Consulting Engr.

Sterling, Colo.—Bids are wanted Nov. 10 for the purchase of water works bonds, not less than $40,000 nor more than $63,000, as advertised in The Engineering Record.

San Bernardino, Cal.—City Clk. Legare Allen writes that at the election to be held Dec. 20 a vote will be taken on the issue of water works bonds, as follows: $163,000, $68,000 and $66,000; total, $297,000. All three propositions to be voted upon separately.

Salt Lake City, Utah.—Preliminary work and plans are now being made for work contemplated by the Weber River Irrigation Co., which work includes storage dams for flood water, water power, etc. The company has been organized by the community of irrigators whose source of supply is the Weber River. Probable cost of work, $300,000. Engrs.-in-Charge, Doremus & Kelsey, of Salt Lake City.

Wessington Springs, S. Dak.—This place is said to be considering the project of sinking an artesian well for a water supply and fire protection.

Evans, Colo.—Press reports state that the Union Ditch Co., of Evans, proposes to build a reservoir 3 miles northwest of Longmont; capacity of reservoir, 500,000,000 gals.

The Union Reservoir Co. has been incorporated, with a capital of $25,000, to operate in Weld Co.; principal place of business, Evans. Directors: Jas. S. Barber, A. W. James and others.

Salem, Ore.—Local press reports state that the State of Oregon has awarded contracts, as follows, for the reclamation of arid land: To the Pilot Butte Development Co., of which A. M. Drake is Pres., for the reclamation of 84,707 acres of land, the main body of which lies south and east of the town of Bend in Cook Co.; to the Oregon Development Co., of which J. E. Morson is Pres., 68,091 acres of land in the southern part of Cook Co. and the northern part of Klamath Co.

Sacramento, Cal.—Bids are wanted Dec. 15 for the purchase of $150,000 bonds to complete the system of water mains for this city. M. J. Desmond, City Clk. C. M. Phinney, Deputy City Surveyor, writes that as soon as said bonds are sold it is presumed the City Trus. will adopt specifications and let contracts for laying water mains.

Santa Ana, Cal.—P. H. Krick, Secy. Anaheim Union Water Co., writes that said Co. proposes to cement its main canal from Placentia to the head gate at a probable cost of $110,000. The work is likely to be done under the supervision of the Co.'s superintendent, and will require several years for completion. G. W. Sherwood, of Fullerton, Engr.-in-Charge. Said Co. is investigating site for dam and reservoir which may be built at a probable cost of $75,000. C. C. Chapman, of Fullerton, and Fred. Eaton, of Los Angeles, are interested.

Grand Junction, Colo.—The Council is said to contemplate the expenditure of $10,000 in improving the water works system. A 3,000,000-gal. pump is to be bought.

Basalt, Colo.—At a special election to be held Nov. 12 a vote will be taken on proposition to construct a municipal system of water works. I. H. Mitchell, Town Clk.

San Jose, Cal.—Local press reports state that the Spring Valley Water Co., of which Mr. Scussler is Supt., has in contemplation extensive improvements, including the construction of a large reservoir.

Denver, Colo.—The Denver Eureka Power Co. has been incorporated by G. H. Sethman, W. H. Sherrod and W. F. Sperry, of Denver, with a capital of $3,000,000. The articles of incorporation set forth that it is the purpose of the company to generate power and to take water from Middle Boulder Creek and to convey it to patrons throughout the State. In addition to irrigation projects it is proposed to generate and sell electricity.

Los Angeles, Cal.—The Imperial Water Co., No. 7, principal place of business, Los Angeles, has been incorporated by W. F. Holt, R. T. Perry, F. C. Paulin and others. Capital stock, $200,000.

The Sierra Vista Water Co., principal place of business, Los Angeles, has been incorporated by C. S. Munn, M. P. Phipps, F. A. Nance and others. Capital stock, $100,000.

San Francisco, Cal.—The Bay Cities Water Co. has been incorporated with a capital of $10,000,000. The incorporators are Wm. S. Tevis, Clinton E. Worden, Henry L. Tevis and others. According to local press reports the watershed which the company has secured comprises an area of about 250 square miles, beginning about 10 miles southeasterly from San Jose and extending back into the mountains, embodying the valleys of the Coyote, the San Felipe, Las Animas, Packwood and numerous other streams.

Cheney, Wash.—The Citizens' Com. has reported favorably on the proposition for the city to purchase the water plant.

Bonesteel, S. D.—Water works bonds to the amount of $5,000 are reported to have been voted.

Provo City, Utah.—The Council Water Com. has reported estimating the cost of piping spring water to the city at $29,060 to $33,990. The cost of a filtering apparatus which would be needed if the city did not use water from the springs is estimated at $25,000.

Colorado.—Ch. Hydrographer F. H. Newell, of the Geological Survey, Washington, D. C., is reported to have announced that the first definite selection of sites for irrigation reservoirs to be constructed by the Federal Government has been made. The reservoirs are to be located on St. Mary's River, Montana; the Gunnison River, Colo.; the Carson and Truckee rivers, in Nevada; the Salt and Gila rivers, in Southern Arizona; the Big Horn, in Wyo.; the Sweetwater, in Wyo., and the Grand River, in Colo.

Springville, Utah.—The City Council is said to be considering the issue of bonds for water works and electric lights.

Mancos, Colo.—In a report to the Bd. of Trus. Blair Burwell, C. E., places the estimated cost of a complete system of water works at $20,000.

Montreal, Que.—The Water Com. has awarded the contract for the erection of new pumping building at the high level station to McDonald, Ouimet & Co., for $4,275.

SEWERAGE AND SEWAGE DISPOSAL.

Waterbury, Conn.—The Bd. of Pub. Wks. has awarded contracts for storm water sewers as follows: To Edw. McManus, sewers in Bronson, Bishop and other streets, for $4,596. To Pasquale Contaldi, sewers in North Willow and Ridgewood Sts., for $5,239.

Woonsocket, R. I.—The City Council has made an appropriation for an additional filter bed for sewage disposal.

New Britain, Conn.—Local papers quote Sewer Comr. and Supt. Beach as having stated that work on the trunk sewer and two large interceptors will be started early in the spring.

Laconia, N. H.—The City Council has referred the proposition to construct a system of sewers in that portion of the city known as The Weirs to the Com. on Sewers. Chas. O. Downing, Chmn.

Hartford, Conn.—The contract for constructing Folly Brook culvert has been awarded to Chas. H. Slocum, his bid being $11,352 with expanded metal or $11,758 without metal.

Albany, N. Y.—Mayor Gaus has approved ordinances providing for vitrified pipe sewers in Washington Ave., and Alexander St.

Jersey City, N. J.—The Street and Water Bd. has adopted specifications for proposed sewer in Carleton Ave.

Syracuse, N. Y.—The only bid received Oct. 27 for the construction of the tunnel sewer in the 4th Ward, which is to pass through a hill for a distance of 4,700 ft., is stated to have been from Thos. Moore, at $43,439 for 33-in. brick sewer, or $42,416 for a 28x42-in. web tile sewer.

Brooklyn, N. Y.—Bids will be received Nov. 12 by J. Edw. Swanstrom, Boro. Pres., for furnishing material and constructing sewer in portions of 3 streets. Engineer's estimate is as follows: 1,410 lin. ft. 12 and 15-in. vitrified stoneware pipe sewer laid in concrete, 12 manholes and 2 receiving basins.

Wilkesbarre, Pa.—This city is contemplating a loan of $300,000 for sewer, street and Fire Dept. improvements.

Newark, N. J.—Plans for a sewer along Badger Ave. and Peddie St., to cost about $140,000, were submitted by City Engr. Ernest Adam at a committee meeting of the Bd. of Wks. Oct. 28. The specifications were recommended for approval.

Brooklyn, N. Y.—The following bids for constructing a sewer in 92d St. from 11th Ave. to N. Y. Bay were opened Oct. 29 by J. Edw. Swanstrom, Boro. Pres.: A, Jas. Malloy & Co., Williamsbridge, N. Y.; B, John J. Creem, 799 Willoughby Ave.; C, John McNamee, 16 Court St.:

Items and Quantities.	A	B	C
159-in., triple section outlet, 165 ft. (Sec. F)	$160.	$125.	$110.
Reducing chamber, 1	13,500.	7,500.	10,000.
Circular brick sewer, in tunnel:

Niagara Falls, N. Y.—Chasm Ave. trunk sewer bonds, to the amount of $27,000, have been sold by the Bd. of Pub. Wks.

Jamestown, N. Y.—Bd. of Pub. Wks. recommends the extension of the sewer system at a cost of $40,000.

Paterson, N. J.—The executive committee of the Citizens' Association is reported to have made arrangements with Samuel M. Gray, of Providence, R. I., to make preliminary examination hydraulic and topographical of the Passaic River, together with an investigation of the sewerage system of Paterson, to ascertain what system will be best for the disposal of the sewage of this city.

Findlay, O.—Bids will be received by Frank C. Ray, Clk. of Bd. of Improv., Nov. 6, for constructing a sewer in a portion of East Main-Cross St., known as combined local sewer No. 1 in Sub-Dist. No. 1 of sewer Dist. No. 2; also for constructing a sewer in a portion of West Hardin St., known as combined local sewer No. 8, in Sub-Dist. No. 2 of sewer Dist. No. 2.

Canal Dover, O.—Bids are wanted Nov. 20 for furnishing material and constructing a storm water sewer in Calico Ditch in portions of Broad St. Approximate quantities of the work to be done are as follows: 1,549 lin. ft. of 2-ring brick sewer 36 in. in diameter; 450 lin. ft. 12-in. first class double strength, vitrified pipe sewer; 200 lin. ft. 24-in. first class double strength, vitrified pipe; 6 catch basins, 5 manholes and 1 concrete outlet pier. Alfred Nydegger, Village Clk.

Davenport, Ia.—Bids will be received Nov. 4 by the Bd. of Pub. Wks. for constructing 1,078 lin. ft. of 10-in. pipe sewer in portions of 2 streets. Thos. Murray, City Engr.

Eau Claire, Wis.—Bids are wanted Nov. 5 for constructing a sewer on 2d Ave. and Fulton St. Martin Severson, Chmn. Com. on Sewers.

Cincinnati, O.—Bids will be received by the Bd. of Pub. Service Nov. 12 for the construction of sewers and drains in portions of Grace Ave. and Ferdinand alley, and on Nov. 26 for constructing sewers and drains in portions of Observatory Ave., State Ave. and the ravine west of Torrence road. Robt. Allison, Pres.

The contract for constructing Linwood Ave. sewer has been awarded to F. H. Kirchner & Co. for $51,596. The City Engr's estimate was $51,891. The other bids were as follows: T. P. Strack, $51,623; Thomas Maloney, $53,416; A. J. Henkel & Bro., $52,439; VanSandt & Meeds, $52,016.

Grand Rapids, Mich.—Local press reports state that the following bids were opened Oct. 17 for building the West Side sewer: *a*, with concrete; *b*, with a combination of steel and concrete: Albert Prange, *a*, $120,347; *b*, $120,937; Jas. McDermott, *a*, $124,115, *b*, $124,469; H. A. Heinman, of Chicago, $147,248.

Springfield, O.—The Bd. of Pub. Affairs has passed 4 ordinances for the construction of main sewers for the carrying off of surface water.

Brazil, Ind.—The contract for constructing Franklin St. sewer has been awarded to W. C. Dorsey, of Terre Haute, Ind., for $6,372. The sewer is said to be about 5,000 ft. in length.

Toledo, O.—The Sewer Com. of the City Council has decided upon the location of the main sewer for Sewer Dist. No. 36, draining Walbridge Park and vicinity; also the location (on Swan Creek, near Champion St.) for a disposal plant for same.

Wabash, Ind.—The contract for constructing a sanitary sewer in Main St. has been awarded to Philip Hipskind & Sons at $1.16 per lin. ft.

Shenandoah, Ia.—City Clk. J. Swain writes that the contract for constructing sewers on Summit and Valley Aves. (bids opened Oct. 20) has been awarded to Dunnegan & Sullivan, as follows: 6-in. junction at 50 cts. per ft.; 8, 10, 12 and 15-in. pipe at 65 cts., 70 cts., 75 cts. and 85 cts., respectively; manhole at $35; catch basins, $40, and flush tanks at $95.

Elk Rapids, Mich.—It is reported that a portion of the sewer system designed recently by Blomshield & McCloy, of Bay City, Mich., will be built soon.

Lake Park, Minn.—See "Water."

Chicago, Ill.—Bids are wanted Nov. 6 for constructing sewers in several streets. John C. May, Secy.

According to local press reports the city officials have agreed upon plans for draining the southwest part of the city. Probable cost of proposed sewers about $1,000,000.

Johnson City, Tex.—Local press reports state that this city has decided to secure the services of an engineer to prepare plans and specifications for a sewer system.

Oak Cliff, Tex.—C. F. Cohron, representing Dr. E. G. Patton, W. I. Addison and others, who have organized the Citizens' Sewerage Co., has asked the City Council for a 50-year franchise.

Marysville, Cal.—The Common Council has taken preliminary steps toward the construction of a sewerage system. Bonds to the amount of $50,000 will probably be issued.

Long Beach, Cal.—The City Council Com. on Pub. Wks. and City Engr. Foster are preparing plans for the proposed sewerage system. Mr. Wallbrick, of Los Angeles, is Consulting Engr.

Colorado Springs, Colo.—The Special Drainage Com. has reported at a recent meeting of the operators of Cripple Creek Dist., recommending the construction of a tunnel, not to exceed 10,000 ft. in length, to drain the mines of Cripple Creek Dist. Sherwood Aldrich, Chmn. of Com.

Toronto, Ont.—City Engr. Rust, in a recent report to the Bd. of Control recommends, as the most satisfactory and economical method of disposal, that crude sewage be taken out into the lake 9 miles east of the water works pipe, or if ratepayers are opposed to this plan he recommends the treatment of sewage in septic tanks. The cost of this method of disposal is $635,000 more than the first plan recommended, and the annual cost $60,000.

BRIDGES.

Norwich, Conn.—The County Bd. has adopted a resolution to the effect that the Selectmen shall without delay cause to be built an iron or steel footbridge across Yantic River near the Falls, said bridge to pass over the tracks of the Central Vt R. R.

Dalton, Mass.—Local press reports state that new iron bridges of a heavier tonnage capacity are to be placed on the Pittsfield trolley line between Knight's Hill and Wayside, replacing those now in use.

Pittsburg, Pa.—Upon the recommendation of Capt. W. L. Sibert, U. S. Engineer at Pittsburg, the War Dept. has indorsed the raising of Union St. and 6th St. bridges across Allegheny River.

Philadelphia, Pa.—Local press reports state that the Survey Com. of the Councils will probably soon recommend the passage of an ordinance to build a bridge over Allegheny Ave. near 9th St. Probable cost, $60,000.

New York, N. Y.—The New York Central R. R. Co. is reported to have agreed to bear the expense of building a bridge over the tracks at 233d St., the city to purchase property for the approach.

Oswego, N. Y.—State Bridge Inspector W. H. Davis, after an examination of the Oswego River bridge connecting East and West Oswego, has condemned the structure and recommended that it be closed to traffic and repairs to the amount of $40,000 be made, or a new bridge costing $120,000 be built.

Harrisburg, Pa.—Bids are wanted Nov. 18 for rebuilding the substructure and superstructure of 8 bridges to be erected by the State and located in the following counties: Perry, 1; Columbia, 2; Centre, 1; Lycoming, 1, and Wayne, 3. The total cost to be about $135,000. T. L. Eyre, Supt. Bd. of Comrs. of Pub. Grounds and Bldgs.

Press reports state that the Northern Central Ry. proposes to build a new steel bridge across the Susquehanna at a point below Harrisburg. W. H. Brown, Ch. Engr., Philadelphia.

Contracts for the erection of the Harrisburg Bridge Co.'s Market St. bridge are stated to have been awarded as follows: Steel structure and erection, to the Pennsylvania Steel Co., for $152,500; the thirty piers of stone, to H. S. Kerbaugh & Co., for $95,000. According to press reports the bridge is to be 2,800 ft. in length, with an asphalt floor. The roadway will be 18 ft. between curbs, with a footwalk 7 ft. wide.

Schenectady, N. Y.—Local press reports state that the Schenectady Ry. Co. is investigating the feasibility of constructing a bridge across the Mohawk above the dam at aqueduct. R. H. Fraser, Mgr., Schenectady.

Doylestown, Pa.—Local press reports state that bids will be received Nov. 20 by the Township Clk. for constructing a bridge at Leatherman's Ford across Deep Run Creek in Bedminster Township.

West Point, Va.—The question of having the county erect an iron bridge at Norments, on Pamunkey River, is being agitated.

Miami, Fla.—The County Comrs. have received permission from the Secy. of War to build a steel bridge, to be about 200 ft. long with 16-ft. driveway and 5-ft. walk, across Miami River at the foot of Ave. D.

Paoli, Ind.—Bids will be received Nov. 6 by the Bd. of Co. Comrs. for constructing a bridge over the bayou on Lost River, in North West township; also for constructing a bridge over Sam's Branch in French Lick township. John H. Weeks, Chmn.

Oskaloosa, Ia.—Bids will be received by the Bd. of Co. Supervisors Nov. 12 for constructing an iron bridge, 110 ft. in length, across South Skunk, to be built by Jan. 1, 1903; also an iron bridge, 93 ft. in length, across North Skunk River, to be built Aug. 1, 1903.

Moline, Ill.—The Bridge Com. of the Co. Bd. of Superv. is investigating sites at Cleveland and Colona for the proposed bridge to cross Rock River.

Bay City, Mich.—The Bay County Road Comn. has asked for bids on the sub-structure for new bridge across KawKawlin River. Blomshield & McCloy, of Bay City, are the consulting engineers.

Chicago, Ill.—Bids will be received Dec. 17 by A. R. Porter, Sanitary Dist. Clk., Security Bldg., for constructing the superstructure of a bridge across Chicago River and main drainage channel of the Sanitary Dist.

Cincinnati, O.—A press report states that the old wooden Ida St. bridge will probably be replaced by a steel or iron structure. This is urged by the U. S. Marshal, V. J. Fagin, in a letter to the Bd. of Pub. Service.

Lebanon, O.—Bids are wanted Nov. 18 for $40,000 county bridge bonds. S. A. Stilwell, Co. Aud.

Monmouth, Ill.—It is stated that bids are wanted Nov. 5 for constructing a steel bridge on stone or concrete abutments in Swan Township. H. B. Roberts, Town Clk.

Marshalltown, Ia.—The Council has passed an ordinance providing for the construction of a viaduct across the R. R. tracks on Center St.; probable cost, $60,000.

Vicksburg, Miss.—U. S. Secy. E. Root is stated to have approved plans and authorized the construction of a viaduct over Stouts Bayou on the battlefield of Vicksburg.

Oakville, Tex.—Judge T. S. Johnson, Office Assistant Attorney General at Austin, Oct. 21 approved $8,000 of Live Oak County bridge bonds.

Oberlin, Kan.—It is stated that bids will be received Nov. 13 by J. E. Platts, Co. Clk., for constructing a steel bridge over Sappa Creek.

Gannvalley, S. D.—Bids are wanted Nov. 8 for constructing a bridge across Elm Creek. W. H. Abernathy, Co. Aud.

Sulphur Springs, Colo.—The Grand Co. Comrs. are stated to have awarded to Wm. C. Call the contract for a bridge across Grand River at Kremmling, for $5,000.

Centralia, Wash.—It is stated that bids are wanted Nov. 9 for constructing a bridge across Cowlitz River at Mayfield, span to be 140 ft. long. A. Schooley, Co. Aud.

Goldendale, Wash.—It is stated that bids are wanted Nov. 8 for constructing a bridge across the little Klickitat River on the Goldendale and Yakima Roads. Address Wm. McEwen.

Folsom, Cal.—It is stated that bids are wanted Nov. 6 for constructing a stone arch bridge at Alden Creek. V. B. Hamilton, Clk. Superv., Sacramento.

PAVING AND ROADMAKING.

Thomaston, Conn.—Bids will be received Nov. 7 by the Town Bd. of Selectmen for the grading of 3 sections of road in this town. Geo. P. Bradstreet, Chmn. Bd. of Selectmen.

Syracuse, N. Y.—The Council has designated brick as the material to be used for the paving of East and West Colvin Sts., the lowest bid for which was from John W. Bustin, of Syracuse, at $27,487, using N. Y. Brick & Paving Co.'s brick.

Cohoes, N. Y.—Local press reports state that bids will be received by the Pub. Improv. Comn. Nov. 12 for paving Amity St.

Niagara Falls, N. Y.—The Common Council has declared its intention to pave Niagara Ave. with asphalt.

Pittsburg, Pa.—The Bd. of Pub. Wks. has affirmatively recommended ordinances for grading, paving and curbing Griffin, Sterrett, Orphan, Beatty, Matthew and other streets.

Binghamton, N. Y.—Local papers quote State Inspector of Good Roads Frank D. Lyon as having stated that about $100,000 will probably be expended next year in the improvement of State roads leading into this city.

Baltimore, Md.—Two ordinances have been introduced in the 1st Branch of the Council for the paving of O'Donnell St.; one provides for asphalt block at a cost of $47,395, and the other provides for wood blocks at a cost of $49,900.

Brooklyn, N. Y.—The following bids for macadam pavement on Albany Ave. from Lincoln Rd. to Clarkson St. were opened Oct. 29, by J. Edw. Swanstrom, Boro. Pres.: A, Jas. P. Graham; B, McDermott & Foxton; C, Thos. F. Byrnes; D, Frank J. Gallagher; E, Dennis Norton; F, Isaac Harris:

Bidders.	Macadam, 9,960 sq. yds.	Excav., 750 cu. yds.	Fill (finished) 1,610 cu. yds.	Belgian blk. gutters, 1,440 sq. yds.	Concrete curb, 4,250 ft.	Cement sidewalk, 20,800 sq. ft.

Totals	$22,591	$18,224	$16,859

Rome, N. Y.—Bids are wanted Nov. 7 for $30,000 street improvement bonds. K. S. Putnam, Chamberlain.

Jersey City, N. J.—The Street and Water Bd. is stated to have awarded the contract for asphalting Orient Ave., from the Boulevard to Bergen Ave., at 87⅞ per cent. of the Ch. Engr's standard price, or about $1.54 per sq. yd.

Wilkesbarre, Pa.—See "Sewerage and Sewage Disposal."

Washington, D. C.—The contract for constructing the riverside speedway, which will extend about 1 mile through Potomac Park, is stated to have been awarded to Martin McNamara, of Washington; it is to be built of telford and macadam and will cost about $50,000.

Fredericksburg, Va.—Engr. C. E. Dickinson writes that the contract for paving Commerce and Main Sts. (bids opened Oct. 20) has been awarded to G. A. Gude, of Richmond, Va., as follows: 10,756 sq. yds. granite spalls on sand at $1.10, 3,727 cu. yds. excavating at 40 cts., 4,464 lin. ft. curbing at 90 cts., 161 cu. yds. of concrete at $6, etc.; total, $23,466.

Cincinnati, O.—The Bd. of Pub. Service has decided to improve Rockdale Ave. with asphalt.

Salem, O.—City Engr. B. M. French writes that the City Council has adopted plans and specifications and passed resolutions for the construction of 30,000 sq. yds. of asphalt pavement. Contracts to be let some time in March, 1903.

Danville, Ill.—Press reports state that the Council has decided to pave Washington St.

Lockland, O.—The Council has authorized the issue of $6,000 street-improvement bonds, according to press reports.

Cincinnati, O.—The Bd. of Pub. Service has directed the City Engr. to prepare plans and specifications for the improvement of Reading Road, from Rockdale Ave. to Burnet Ave., with asphalt. One-fourth of the cost will be paid by the city, the remainder by property owners.

Bids are wanted Nov. 17 for improving portions of Pleasant St. by paving the roadway with asphalt, setting curbs, etc. Robert Allison, Pres. Bd. of Pub. Service.

Pontiac, Mich.—City Engr. Wm. J. Fisher writes that bids will be wanted about Feb. or Mar. of 1903 for paving Huron St. west from Saginaw St. to Johnson Ave. Probable cost $75,000.

Ft. Dodge, Ia.—The City Council is said to have under consideration the paving of portions of 8th St. and 1st Ave.

Aurora, Ill.—Petitions are being circulated for the paving of portions of 2d Ave. and Benton St. with asphalt.

Duluth, Minn.—The Council has been petitioned to pave E. Superior St. from 16th and 23d with asphalt.

Toledo, O.—The Toledo Railways & Light Co., through Gen. Mgr. Beilstein, has signified to Mayor Jones its intention to pave St. Clair St., between Knapp and Newton Sts., as provided in the franchise granted the Metropolitan St. Ry. Co. some years ago.

Des Moines, Ia.—City Engr. John W. Budd writes that the following bids were opened Oct. 22 for the improvement of several streets by paving with asphalt:

Items and Quantities.	Barber Asph. Paving Co.	Andrew Jaicks, Chicago, Ill.	Western Const. Co., Lafayette, Ind.
E. Walnut St., 20,300 sq. yds...	$1.96	$1.99	$2.07
E. 12th St., 22,789 sq. yds.....	1.975	1.99	2.07
*E. 5th St., 4,856 sq. yds.......	1.50	1.70	1.77
*Maple St., 1,727 sq. yds.......	1.50	1.70	1.77
Extra concrete, per cu. yd......	4.00	4.45	3.75
Extra gravel, per cu. yd........	1.40	1.60	1.60

*Asphalt on E. 5th and Maple Sts. to be laid on old concrete.

The lowest bids received at the same time for paving with brick on a 6-in. concrete foundation were as follows: O. P. Herrick, of Des Moines, at $1.69 per yd. for 1,962 sq. yds. in State St., and Bennett Bros., Des Moines, at $1.73 per sq. yd. for 1,009 sq. yds. in Alley Blk. 32 Ft. Des Moines.

The lowest bids for Portland cement curbing in several streets were from J. C. Likes, of Des Moines, as follows: W. 10th St., 2,098 lin. ft.; W. 15th St., 1,284 lin. ft., and W. 16th St., 1,678 lin. ft., each at 45 cts. per lin. ft.; W. 12th St., 4,626 lin. ft., at 44 cts. per lin. ft.

St. Joseph, Mo.—Ordinances under consideration provide for the paving of Julie St., from 6th to 19th Sts., with brick.

Beaumont, Tex.—The Street and Bridge Com. has been authorized to have additional pavement laid at a cost of $15,000.

Guthrie, Okla. Ter.—City Engr. T. A. White writes that this city will receive bids Dec. 11 for about 40,000 sq. yds. of vitrified brick paving on concrete foundation. Geo. Sendelbach, City Clk.

Hamilton, Ont.—Co. Clk. J. N. Jardine writes that on Oct. 22 it was voted to issue $98,000 bonds for the improvement of county roads and the purchase of existing toll roads in Wentworth Co.

POWER PLANTS, GAS AND ELECTRICITY.

Taunton, Mass.—Abner Coleman, Mgr. Municipal Lighting Plant, writes that the following bids were opened Oct. 11 for furnishing materials and constructing a municipal light and power station: D. J. Sullivan, Taunton, $50,749; F. D. Williams, Taunton, $43,100; F. B. Gilbreth, Boston, $42,887; Benj. F. Smith Co., Pawtucket, R. I., $36,000; J. W. Bishop Co., Worcester, $35,180 (awarded).

Jamestown, N. Y.—The Bd. of Pub. Wks. is stated to have recommended that a $40,000 addition be constructed to the electric light plant.

Patchogue, L. I., N. Y.—The Brook Haven Gas Co., of Patchogue, has been incorporated; capital, $65,000. Directors: Edwin Bailey, J. L. Gerety and A. H. Carmon, Patchogue.

Brooklyn, N. Y.—A permit has been issued for the construction of a gas tank, 170 ft. diameter, for the Brooklyn Gas Co., to be constructed on Belmont and Williams Aves., to cost $225,000. Architects Bartlett, Heyward & Co., of Baltimore, Md. Builders, J. H. Davies & Bro., United Charity Bldg., N. Y. City.

Bids will be received Nov. 10 by C. B. J. Snyder, Supt. of School Bldgs., N. Y. City, for installing electric light wiring, fixtures, etc., in School No. 138, Boro. of Brooklyn.

Niagara Falls, N. Y.—The Council is stated to have granted a franchise to the Ontario Transmission Co. to string its wires and furnish electricity in this city. The company has petitioned for a franchise in La Salle.

Canandaigua, N. Y.—H. A. Rose is stated to have petitioned the Village Trus. for a franchise to lay pipes and operate a plant to supply natural gas from a well in West Bloomfield.

Port Royal, Pa.—The Boro. Council is stated to have granted a franchise to the Juniata Electric Light Co.

South Bethlehem, Pa.—The Fountain Hill & West Bethlehem Light, Heat & Power Co. and the Consumers' Light, Heat & Power Co., both of South Bethlehem, have been incorporated, each with a capital of $1,000.

Baltimore, Md.—Bids will be received Nov. 5 by Geo. N. Numsen, City Register, for installing and maintaining such number of naphtha street lamps (using incandescent mantles) as may be necessary for a term of 1, 2, 3 and 5 years, beginning Jan. 1, 1903. Robt. J. McCuen, Supt. of Lamps & Lighting.

Penngrove, N. J.—Bids will be received Nov. 12 by the Mayor and Council for constructing an electric light plant, consisting of approximately one 105 H.-P. engine, one 60 Kw., 60 cycle, single-phase generator, switchboard, power, etc. John P. Leap, Chmn. Water Com.

Villa Rica, Ga.—The Villa Rica Light & Power Co. is reported organized, with C. M. Griffin, Pres., and E. R. Ayers, Secy. A plant will soon be constructed.

Morgantown, W. Va.—Geo. H. Switzer, Supt. of Construction, writes that the Bd. of Dirs. of the Morgantown Electric Light & Power Co. have authorized him to contract with the Stirling Co., of Chicago, Ill., for 3 boilers aggregating 910 H.-P., with Westinghouse, Church, Kerr & Co., New York City, for two 325 H.-P. and two 275 H.-P. Westinghouse compound engines, and with Westinghouse Elec. & Mfg. Co., Pittsburg, for two 200 Kw., 600 volt engine-type generators with switchboard and two 180 Kw., 2,200 volt, 60-cycle, two phase, belted alternators, with switchboard; total amount, $46,500. (Bids opened Oct. 24.)

Muncie, Ind.—The City Council is stated to have granted a franchise to the Mutual Gas Co.

Janesville, Wis.—The property of the Janesville Electric Co. is reported to have passed into the hands of a company of local capitalists, Stanley B. Smith, Levi B. Carle being among the new stockholders. The company is to be entirely reorganized and the capital stock increased from $30,000 to $100,000.

Superior, Wis.—The Highland Canal & Power Co. is reported to have purchased the Jay Cooke water power on the St. Louis River and will develop the power as required.

Escanaba, Mich.—The citizens are stated to have voted to issue $50,000 bonds to purchase the gas and electric plant of the Lighting Co.

Minneapolis, Minn.—A permit has been issued to J. H. Edmonds and L. M. Hill for a 4-story brick flat to be erected at 311-17 W. 15th St., to cost $20,000.

Kansas City, Mo.—S. R. Frink, Mass. Bldg., has prepared plans for a $20,000 brick dwelling, to be erected at 15th and Wabash Ave. Owner, W. A. Rule.

San Francisco, Cal.—Shea & Shea, 26 Montgomery St., are stated to have prepared plans for an 8-story fireproof building, to be erected on Mason and Ellis Sts. for Mr. and Mrs. A. F. Charnot, to cost about $100,000.

New York City.

Permits for the following buildings have been issued: c, signifies cost; o, owner; a, architect; m, mason; cr, carpenter; and b, builder.

299 to 305 E 8th St, 2 6-story br tenemts; c, total, $90,000; o, Nathan Silverson; a, G T Pelham.

72d St and Ave A, 5-story br and stone flat; c, $20,000; o, Godfrey Knoche; a, Rudolph Moeller.

117th St and 5th Ave, 6-story br flat; c, $65,000; o, Chas Adams; a, Lorenz F J Welher.

Union Ave and 168th St, 5-story br tenemt; c, $25,000; o, Frank Mezger; a, Vincent Bonagm.

1 E 42d St, 5-story extension to 4 and 5-story br dwell; c, $25,000; o, Mrs Margaret Schley; a, Chas E. Reid.

Brooklyn, N. Y.

43d St and 5th Ave, 9 3-story br dwells; c, total, $36,000; o, J K Stockton & O Abram; a, H. L. Spicer.

SCHOOLS.

New Bedford, Mass.—City Engr. W. F. Williams writes that plans are being prepared by S. C. Hunt, of this city, for a high school which will probably cost $500,000 or more. Contracts will not be let before 1903, as certain legislation must first be secured.

Pawtucket, R. I.—Frank G. Rowley, 161 Main St., is stated to have secured the contract for erecting the South Woodlawn school, for $36,571.

Boston, Mass.—Bids will be received Nov. 10 by the Schoolhouse Comrs. for erecting a school on Norman St., Phillips Dist., exclusive of plumbing, heating and electrical work and giving bond for the sum of $50,000. Everett & Mead, Archts., 60 Devonshire St. R. Clipston Sturgis, Chmn.

New York, N. Y.—Bids will be received Nov. 10 by C. B. J. Snyder, Supt. of School Bldgs., for alterations and repairs to the 3 buildings in E. 52d St., converting them into annex of school No. 18; also to a building in E. 46th St., converting it into annex of school No. 73.

Bids will be received Nov. 7 by C. B. J. Snyder, Supt. of School Bldgs., for erecting a school at 176 Amethyst Ave., and for installing electric elevators in Morris High School, Boro. Bronx. Bids will also be received for erecting 2 outside iron stairs at front of school No. 70, Boro. Manhattan.

The following bids were opened Oct. 24 by Supt. of School Bldgs., C. B. J. Snyder, Dept. of Educ., for installing electric elevators in the new High School of Commerce, Manhattan Boro.: Marine Engine & Machine Co., $9,745; Otis Elevator Co., 71 Broadway, $9,994.

Brooklyn, N. Y.—The followings bids were opened Oct. 22 by Supt. of School Bldgs., C. B. J. Snyder, Dept. of Educ., New York City, for installing heating and ventilating apparatus for school 139, Boro. of Brooklyn: Williams & Gerstle, $18,934; John Neal's Sons, $19,910; Frank Dobson, $18,832; United Heating Co., $18,741; Jas. Curran Mfg. Co., $21,000; E. Rutzler, 178 Centre St., $18,240.

Bids opened Oct. 24 for installing electric light wiring, fixtures and electric bell system in school 139, were as follows: Fred'k Pearce, $6,350; Weiderman & Conklin, $7,507; United Engineering & Contracting Co., 21 Park Row, $4,995; T. Fred'k Jackson, $6,410; Commercial Const. Co., $6,300.

Bids opened Oct. 24 for electric light wiring, fixtures, etc., in school 141, Boro. of Brooklyn, were as follows: T. Fred'k Jackson, $8,410; Commercial Const. Co., $8,375; Fred'k Pearce, $8,350; United Engineering & Contracting Co., $7,492.

Ithaca, N. Y.—The Trus. of Cornell Univ. are stated to have agreed on the location of the Rockefeller Hall of Physics, to cost $250,000, and have recommended the erection of a hall for arts and humanities, to cost $250,000. A site is also reported purchased west of the library, and on it 6 new costly buildings will be erected at once and 8 more in the remote future.

Bordentown, N. J.—The contract for erecting the Manual Training and Industrial School for Colored Youths, at Bordentown, is stated to have been awarded to Jas. W. Lanning, of Trenton, for $20,000.

Braddock, Pa.—E. J. Carlisle & Co., Lewis Blk., Pittsburg, are stated to be completing plans for the Carnegie Sub-District School, to be erected on Talbot Ave. and 11th St., Braddock, to cost about $80,000.

Philadelphia, Pa.—The Councils Com. on Schools has recommended that about $2,000,000 be appropriated for permanent school improvements.

Washington, D. C.—The proposition of Pararini & Grier, Washington, to build an 8-room school at 9th and D Sts., N. E., for $33,375, has been accepted by the Comrs., D. C.

Watertown, N. Y.—Bids will be received Nov. 11 by Frank S. Tisdale, Supt. of Schools, for furnishing material and performing the plumbing work for the new high school.

Newburgh, N. Y.—A. H. Pickens, of Newburgh, is stated to have received the contract for ventilating and heating the South St. school, for $6,850.

South Orange, N. J.—Bids are wanted Nov. 11 for erecting the new South Orange school. Chas. Granville Jones, Archt., 280 Bway., New York, N. Y. Wm. H. Kemp, Chmn. Com. on Bldgs.

Brooklyn, N. Y.—Bids will be received Nov. 12 by C. B. J. Snyder, Supt. of School Bldg., N. Y. City, for the general construction of Public school No. 143, Boro. of Brooklyn, and also on same date for installing ventilating and heating apparatus in school No. 138, also in Boro. of Brooklyn.

Mineral Point, Wis.—The citizens are stated to have voted to issue $30,000 bonds for the erection of a school.

Delray, Mich.—Malcomson & Higginbotham, of Detroit, are the architects for a 15-room school to be erected of brick and stone with slate roof and hardwood finish. Cost, $60,000.

Youngstown, O.—Bids are wanted Nov. 10 for furnishing material and erecting a school in sub-district No. 1, Park Hill. R. F. & E. R. Thompson, Archts., Diamond Blk. O. C. Grant Jacobs, Clk. of Youngstown Township.

Fayetteville, Ark.—The shops of the Univ. of Arkansas are reported to have been destroyed by fire Oct. 20.

Danville, Ky.—Augustus Rogers, Supt. Kentucky School for Deaf Mutes, writes that no contracts were let for the work on the contemplated new buildings, bids for which were opened Oct. 28, as all bids exceeded the amount of the State's appropriation. The architect is at work on new plans, and it will be several months before the matter will be taken up again.

Ft. Morgan, Colo.—M. W. Fuller is stated to be preparing plans for a high school, to cost $35,000.

San Francisco, Cal.—The Bd. of Educ. is stated to have adopted plans for the Noe Valley School, to cost about $40,000.

Berkeley, Cal.—Bids are wanted Nov. 22 for erecting a recitation and dormitory building, including plumbing, gasfitting, heating, etc. W. H. Weeks, Archt., Watsonville; E. J. Wickson, Secy. Bd. of Trus. of the California Polytechnic School.

STREET CLEANING AND GARBAGE DISPOSAL.

Bridgeport, Conn.—This city is said to be considering a proposition from the United States Garbage Reduction Co. of Boston for the disposal of garbage and ashes for a term of years.

Newburyport, Mass.—The City Council is considering the question of garbage disposal by cremation.

New York, N. Y.—Bids are wanted Nov. 7 (re-advertisement) for furnishing labor and materials required for the removal of snow and ice of the Boro. of Manhattan until Apr. 15, 1903. John McG. Woodbury, Comr. of Street Cleaning.

Brooklyn, N. Y.—The Bd. of Estimate has approved the award of a 5-year contract for the removal of ashes and rubbish collected in Brooklyn to H. M. Kennedy.

Parkersburg, W. Va.—Bids will be received Nov. 12 by the Health Com. for the removal of all kitchen garbage and offal accumulating in this city for 1 year beginning Jan. 1, 1903. Jesse L. Cramer, City Clk.

Elwood, Ind.—The City Council has appointed a special committee composed of Mayor W. C. Smith and Councilmen Brown, Ploughe and Haynes to visit other cities and inspect garbage furnaces with a view of having the one here rebuilt.

Marietta, O.—The City Council is said to be receiving bids for 15 and 20-ton garbage crematories.

Kansas City, Mo.—John T. Elkins has made a proposition to the Joint Garbage Com. for the collection and disposal of city garbage.

Montreal, Que.—Bids are wanted Nov. 6 for the removal of snow and ice from the streets in which the Montreal St. Ry. Co. runs its cars. Contracts may be awarded for 1 or 3 years at the option of the City Council. Address L. O. David, City Clk.

GOVERNMENT WORK.

Boston, Mass.—Bids are wanted at the U. S. Engineer Office until Dec. 2 for dredging in Chelsea Creek and Malden River, as advertised in The Engineering Record.

Washington, D. C.—Bids are wanted at the U. S. Engineer Office until Nov. 26 for dredging and for furnishing and placing rip-rap stone in Anacostia River, D. C., as advertised in The Engineering Record.

Wilmington, Del.—U. S. Engr. Jared A. Smith is stated to have received the following bids Oct. 23 for extensive improvements to streams and harbors along the Eastern Shore of Maryland, the entire project to cost about $90,000: American Paving & Const. Co., of Philadelphia, 19 cts. a cu. yd. for dredging; Maryland Dredging & Const. Co., of Baltimore, 20½ cts. a cu. yd.; Sanford & Brooks Co., of Baltimore, 23 cts. a cu. yd.; River & Harbor Improv. Co., of Philadelphia, 24 cts. a cu. yd.; American Dredging Co., of Philadelphia, 26 cts. a cu. yd.

Patchogue, L. I., N. Y.—The contract for dredging the big channel of Great South Bay is stated to have been awarded to Kirk, Driscoll & Co., of Syracuse, for about $65,000.

Philadelphia, Pa.—The American Paving & Con. Co., of Philadelphia, has been awarded a contract by Mordecai T. Endicott, Ch. of Bureau of Yards and Docks, Washington, for the coppersmith shop addition to the steam engineering building at League Island Navy Yard, for $102,570.

Annapolis, Md.—The lowest bid received Oct. 22 for dredging the channel from Chesapeake Bay to the Naval Academy is stated to have been from the Baltimore Dredging Co., of Baltimore, at $195,000.

Brunswick, Ga.—The following bids were opened Oct. 23 by Capt. Cassius E. Gillette, Corps of Engrs., U. S. A., at Savannah, for 560,000 cu. yds. of dredging in Inner Harbor, Brunswick: Atlantic Gulf & Pacific Co., New York, N. Y., 21.1 cts. per cu. yd.; R. Moore, Agent, Tallulah Falls, Ga., 22 cts.; Bowers Southern Dredging Co., Galveston, Tex., 23 cts.; Morris & Cummings Dredging Co., New York, N. Y., 20 cts., total $112,000 (recommended for award); P. Sanford Ross, Inc., Jersey City, N. J., 20.9 cts. Amount available, $117,000

Savannah, Ga.—The following bids were opened Oct. 23 by Capt. Cassius E. Gillette, Corps of Engrs., U. S. A., for dredging Savannah Harbor: Amount available, $1,055,000.

Bidder and Addresses.	Lot No. 1, 3,310,000 cu. yds. Cts.	Lot No. 2, 2,800,000 cu. yds. Cts.

*Recommended for award.

Grand Rapids, Mich.—The lowest bid opened Oct. 22 at the U. S. Engineer Office, Grand Rapids, for pier extension and repair of piers and revetment at Ludington, Mich., was from T. J. Bennett & Co., of Muskegon, Mich., at approximately $92,453.

Conneaut, O.—The Donnelly Contracting Co. of Buffalo, N. Y., is stated to have received the government contract for building piers and breakwaters at Conneaut; aggregate amount of contract, $438,000.

Ft. Riley, Kan.—Bids are wanted Nov. 25 for the construction of 2 double sets of quarters, as advertised in The Engineering Record.

Emporia, Kan.—Bids are wanted at the Treasury Dept., Washington, D. C., until Dec. 3 for the construction, including plumbing, heating and ventilating apparatus, electric wiring and conduits, of the U. S. Post Office at Emporia, as advertised in The Engineering Record.

Johnson City, Tenn.—The contract for constructing a dining-hall in connection with the Mountain Branch of the Nat. Soldiers' Home, at Johnson City, is stated to have been awarded to Herman Probst, of New York City, for $124,000.

Anniston, Ala.—Miles & Bradt, of Atlanta, are stated to have been awarded the contract for the erection of the Anniston government building for $59,000.

Bremerton, Wash.—The following bids were opened Oct. 25 at Bureau of Yards & Docks, Navy Dept., Washington, D. C., for constructing an extension of the concrete wing wall, Navy Yard, Bremerton: Bromley & Wells, Seattle, $15,800; Puget Sound Bridge & Dredging Co., Seattle, $14,624; Pacific Construction Co., Seattle, $15,695.

Tacoma, Wash.—Government Engr. Ricksecker, who is in Tacoma in charge of the proposed improvement of the city waterway, has perfected his plans and specifications for the work and forwarded same to Washington for approval. The plans provide for dredging the channel from 11th to 15th Sts., removing the core in the waterway north of 11th St. bridge and extending channel southward from 15th St. Amount available, $175,000.

Ft. Columbia, Wash.—Bids are wanted Nov. 15 for constructing a water and sewer system, etc., at Ft. Columbia. Address Capt. Geo. L. Goodale, Q. M., U. S. Army.

San Francisco, Cal.—The lowest bid received by Cal. Debris Comn. for the construction of the first of the Yuba River barriers above Marysville is stated to have been from the Atlantic, Gulf & Pacific Co. at $27,940.

Ft. Assinniboine, Mont.—Press reports state that among the improvements contemplated for this post is a sewer system to be constructed during the fiscal year.

MISCELLANEOUS.

Buffalo, N. Y.—Bids will be received Nov. 7 by Chas. S. Boyd, Supt. of Pub. Wks., Albany, for deepening and improving the channel of Erie basin, between Buffalo River and slip No. 2.

Buffalo, N. Y.—The Bd. of Aldermen has granted the petition of the Buffalo & Susquehanna Iron Co. for permission to construct a canal across Hamburg turnpike, near the city line.

Syracuse, N. Y.—The contract for the improvement of Onondaga Creek has been awarded to John Kelly for $26,380.

Duluth, Minn.—Local press reports state that the Boston Coal Dock & Wharf Co., that has docks at the west end of this city, will more than double its capacity for another year.

Louisville, Ky.—The Com. on Eastern Parkway and Western Parkway (Chas. F. Grainger, Chmn.) has reported to the Bd. of Park Comrs., placing the estimated cost of each parkway at about $100,000.

Oakland, Cal.—The lowest bid received for reconstructing and widening 12th St. dam is reported to have been from Hutchison, Ransom Co. for $36,000.

Richmond, Que.—Bids are wanted Nov. 7 for the construction of 4 ice piers. Fred. Gelinas, Secy. Dept. of Pub. Wks., Ottawa, Ont.

NEW INDUSTRIAL PLANTS.

The Virginia Vehicle Co., So. Boston, Va., is building a 4-story, 60x250-ft. factory, and is in the market for machinery for iron working and making bodies of vehicles.

The plant of the Springstein Mills, Chester, S. C., was badly damaged by fire and will be rebuilt at once, the new part being 2 stories and about 40x250 ft. Dyeing, drying and dressing machinery will be required.

The Hudson, Mass., Worsted Co. is erecting a 3-story building to be about 200x60 ft. The power plant will be about 150 H.-P.

The plant of the Alpena, Mich., Hoop & Lumber Co. was destroyed by fire, and it is likely that a 2-band mill will be built to replace it.

J. A. Pardue, Quanah, Tex., contemplates erecting a cement mill.

The Decatur, Ill., Bridge Co. is being organized to build bridges and structural steelwork, and contemplates erecting a 70x200-ft. main building; 40x50-ft. blacksmith shop; machine shop, engine room and boiler room, each 25x30 ft.; office building, storehouse, etc. The power plant will include an engine of about 50 H.-P., with generator and boilers of corresponding capacity. Electricity will be used throughout the plant. E. B. Tyler, Muncie, Ind., is interested.

The American Glue Co., 415-429 Atlantic Ave., Boston, Mass., will erect a 2-story, 300x100-ft. brick building at its Springdale, Pa., plant to replace a building recently burned.

The Goderich, Ont., Organ Co., whose plant was recently burned, expects to erect two 2-story and basement buildings, 126x45 and 120x45 ft., respectively; 2-story, 140x40-ft. shipping and stock rooms, and a 140x40-ft. finishing room. A 100-H.-P. engine and a 100-light dynamo will be installed. The company desires catalogues of woodworking and special machinery.

The Johnson-Ingman Air Motor Co., Cumberland, Md., will erect a new plant.

The National Cereal Milling Co., Peoria, Ill., expects to erect a plant next March and install an 800 to 1,000-H.-P. power plant. J. E. Goodrich, Act. Sec'y.

The American Ice & Industries Co., Birmingham, Ala., expects to erect a new plant and install two 60-ton ice machines, 200,000 cu. ft. cold-storage and an electric light plant. W. H. Morris is interested.

A company is being organized in Johnstown, Pa., to erect a brick plant having a daily capacity of not less than 50,000. D. W., W. P. and D. P. Coulter, O. C. Harris and J. Wallace Paul are interested.

The J. Geo. Leyner Engineering Works Co., Denver, Colo., has decided to build new works in some suburb of Denver, as yet not chosen, which will comprise a 2-story brick office building, and the following 1-story brick and steel buildings: 100x224-ft. main machine shop, with central erecting bay: 75x204-ft. warehouse; 60x204-ft. blacksmith and forge shop; 100x144-ft. foundry of 30 tons daily capacity with brass moulding equipment in addition; 50x164-ft. pattern shop; 30x60-ft. pattern storage and a power house. The shops are to be electrically driven throughout and the installation contemplates 100 motors, from 2 to 25 H.-P., aggregating 550 H.-P. The load factor at average load is estimated at one-third, and the preliminary plans for power include four 150-H.-P. tubular boilers, two 200-kilowatt tandem-compound condensing generating units and a compound condensing steam-driven air compressor of 1,000 cu. ft. per min. capacity. Tunnel connections are to be made with the buildings and the hot-blast system of warming will be employed. In addition to the manufacture of air compressors, drills and coal cutters, complete mining equipments are to be built.

The Smith's Falls, Ont., Malleable Iron Works will erect a 250x66-ft. addition to be used for moulding and annealing purposes. No additional power plant will be required.

BUSINESS NOTES.

The American Blower Co., Detroit, Mich., reports the following among recent orders: Heating apparatus for factory of Wickham, Chapman & Co., Springfield, O.; ten large steel plate fans and over 16,000 ft. of heating surface for the University of Chicago; heating plant and forced draft apparatus for the Lehigh Valley Silk Mills, So. Bethlehem, Pa.; mechanical draft apparatus for Bryn Mawr and Wellesley Colleges; heating and drying apparatus for the Lumiere North American Co., Burlington, Vt.; drying apparatus for the Composite Board Co., Niagara Falls, N. Y.

The Ball Engine Co., Erie, Pa., reports the following among recent orders: National Tube Works, Middletown, Pa., two 450-H.-P. direct-connected engines; West Jersey & Seashore Line of the Penna. R. R. Co., Atlantic City, N. J., two 150 H.-P. cross-compound engines.

Sargent, Conant & Co., Boston, Mass., have purchased the construction business of the Hawks Electric Co., of that city, and will complete its outstanding contracts.

The Otis Elevator Co. has recently received the contract for the elevator and dumb-waiter equipment of the new Astor Hotel, New York. The plant consists of seven electric passenger elevators, two electric servants' elevators, eleven electric dumb-waiters, and three electric sidewalk lifts. Clinton & Russell are the architects, and John Downey, the general contractor.

The Berlin Construction Co., Berlin, Conn., has opened an office in the Board of Trade Building, Boston, which is in charge of H. C. Collins, who has been for many years identified with the structural steel business in New England. The company also maintains offices at 220 Broadway, New York, and 142 Market St., Newark, N. J.

The contract for the steel framework for the addition to the Boston Athletic Association Building has been awarded to the New England Structural Co., of Boston.

The Engineering Record, conducted by Henry C. Meyer, is published every Saturday at 21 Park Row, New York. Its opinions on technical subjects are either prepared or revised by specialists.

Subscriptions are received and single copies supplied by the International News Company, Breams Building, Chancery Lane, London.

The subscription rate is $5 a year for the United States, Canada and Mexico, and $6 for other countries in the Postal Union. Remittances should be made by check, New York draft or money order in favor of The Engineering Record. No responsibility is assumed for payments made otherwise, except those for subscriptions to the International News Company.

The John Fritz Medal.

On the evening of October 31, there was a noteworthy gathering at the Waldorf-Astoria of men eminent in engineering and the iron industry. They came from all parts of the country to do honor to one of the greatest iron-masters of the country, to celebrate the eightieth birthday of a clear-thinking, quietly energetic man who began his career when iron was king and has seen all those changes in this industry which has replaced iron by steel. And not only has John Fritz seen these changes of such far-reaching influence in the country's progress, but he has also been responsible for many more of them than people unacquainted with the facts can ever appreciate. He has always let his work speak for him, and as his work appealed only to those in the industry his influence has not been appreciated generally by the public. His place is well expressed in the cablegram from Mr. Schwab, which was read at the birthday banquet: "He has done more for the steel industry than any man living, and we all acknowledge him as our master and prize him as our friend."

Just what part Mr. Fritz has played in the metallurgy of iron and steel can be guessed best, although imperfectly, from an address on the iron industry that he made before the Franklin Institute a few years ago. His story is so entertaining as well as instructive that all should read it. Aside from its technical and historical value it is everywhere marked by a true manly modesty which is refreshing and endearing in these days of push and puff. This characteristic was well expressed, also, in his brief remarks at the gathering, in which, in acknowledging the honors paid him, he said: "I think of the laboring men who have stood by me and who will ever be held in high regard in my memory. I regret my insufficient education in the inefficient facilities of my native place, but I am glad that my worthy father inculcated in me economy and faithfulness and the religious training that taught me to revere a Supreme Being."

Abram S. Hewitt, also an octogenarian iron-master as well as a man of public affairs, sent a letter that was read at the banquet, in which he pointed out that the life-work of Mr. Fritz affords a very conspicuous example of the operation of American institutions during the century which has just closed. It is not surprising, moreover, to those acquainted with the writer's deep study of national affairs that he should refer to the career of the guest of honor as follows: "That a boy born in humble life, with no advantages of education or opportunities for position, without influential friends or the favoring accidents of fortune, should be able to advance steadily in usefulness, power and the respect of his fellow men, until by common consent he occupies the first place in the domain of practical industry with which he has been connected, gives conclusive evidence that political institutions which afford free play to individual ambition, industry, ability and strict integrity, are worthy of all loyalty and should be cherished and preserved at all costs and hazards. The developments of the twentieth century show that these institutions are in great peril. Their essence is to be found in individual liberty, involving the right of free labor and the acquisition of private property under lawful conditions. When the right of free action shall be suppressed the possibility of a career like that of John Fritz will be destroyed. Collectivism, ending in socialism, may afford other advantages, but let it not be overlooked that these advantages will be obtained only by the sacrifice of personal freedom, and will arrest the progress of civilization due during the ages that have passed to the substitution of freedom for force. John Fritz is a living proof of the results of individual and industrial liberty in a country endowed with boundless resources. In vain shall we seek for a like career in nations or in countries where the individual initiative has been suppressed."

The name and fame of John Fritz have become so endeared to the engineers and iron-masters of this and other countries that nearly five hundred of them have established a fund to pay for a John Fritz Medal to be awarded annually for eminent scientific and industrial achievements. Naturally the first medal was given to the man in whose honor it was established, and the presentation was made by Mr. John Thomson at the banquet. The gathering was an unusual one, even for the Waldorf-Astoria, and the comment of one of the New York papers on its character is worth reprinting: "Although much is heard of American engineering enterprise being in the hands of young men, this gathering presented more bald polls to the raptured sight of the box guests than almost any New York dinner function except the annual banquet of the Chamber of Commerce when a President or Cabinet Ministers are present to make addresses." The first medal was specially prepared for the purpose and consisted of two bronze plaques, for the obverse and reverse sides respectively, and Mr. Thomson stated that he was directed by the founders to announce the award as follows: "We ask that you, John Fritz, accept these bronze plaques, the first John Fritz Medal, the only one of its kind which will ever be presented, as an award made by and coming directly from the founders, our unanimous finding being that, of all the Captains of Industry, this medal may most worthily be bestowed upon you."

The young men in engineering may well reflect on the meaning of this unusual and brilliant affair in honor of one practically unknown to many of them. The Bessemer Medal, hitherto the crowning mark of distinction an iron-master could receive, bears the name of a man of social influence in his youth, of combative temperament, and of considerable financial resources during the perfection of his inventions. The John Fritz Medal, which the founders established with the intention of making it the supreme international award for scientific and industrial achievement, honors a once poor boy whose native abilities made him a great engineer, whose character made him a model citizen, whose modesty has kept him unknown to the public at large. This medal has been founded by no single society, but by contributions from nearly five hundred of Mr. Fritz's professional and business friends and acquaintances; the individual contributions were kept as small as possible in order that the number of contributors might be many. The annual award will be in charge of a committee of representatives of the American Society of Civil Engineers, the American Institute of Mining Engineers, the American Society of Mechanical Engineers and the American Institute of Electrical Engineers. May this committee always administer its trust with the same patience, skill and impartiality that has marked the work of the great engineer in whose honor the medal was established.

John Fritz was born in 1822 in Chester County, Pennsylvania, and at sixteen commenced work in a country machine shop. In 1854 he moved to Johnstown for the purpose of rebuilding the plant of what is now the Cambria Steel Company. In 1860 Fritz returned to the Lehigh Valley and at Bethlehem, Pa., began the construction of a blast furnace, an iron rolling mill for merchant bar and later a mill for rolling iron rails; thus inaugurating the construction of the immense plant now owned by the Bethlehem Steel Company. At a later date, in connection with Alexander Holley, he constructed a plant for making Bessemer steel at this works. He also designed and erected the plant for the fluid compression of steel ingots previous to forging for the Bethlehem Company. It is the only one of its kind in America. The armor making plant with its immense forges operated by hydraulic power, at Bethlehem, was also constructed by Mr. Fritz and in this plant a considerable proportion of the armor used on the warships of the United States Navy was made. After Mr. Fritz resigned his position as manager and superintendent of the Bethlehem Steel Company, the United States Government considered the construction of an armor plant and he was retained to make plans and specifications for such a plant, also estimates as to the cost of producing armor in it. The result of the matter was the wise abandonment of the project by the Government.

At the Louisiana Purchase Exposition the building of the State of Washington is to be in the form of an octagonal tower 114 feet high. The framing is to be all of wood and the main members will be eight great diagonal timbers resting on the foundations and meeting in an apex. Each timber will be over 90 feet long and 24x28 inches in cross-section in one piece.

A High Concrete Dam is to be built at once across the McCloud River, 15 miles east of Baird Station, on the California & Oregon Railroad. The contract has been let for the work and the contractors are just beginning operations. The dam is to be 100 feet high and 700 feet long on the crest. Four hundred feet of the crest will be used as an overflow. The low-water discharge of the river is about 1,300 cubic feet per second. Power is to be generated for use in mines and smelters within 40 miles' radius and also for transmission to cities and towns in the Sacramento Valley. The work is to be completed within fourteen months. Mr. James D. Schuyler, of Los Angeles, is the chief engineer for the work, and Mr. F. S. Hyde is assistant engineer.

The Rio Grande Bridge of the Pacific Railway of Costa Rica.—II.

As stated in the preceding article, the final calculations for the 448-foot spandrel braced arch of the Rio Grande bridge were made by a method derived from the formula

$$H = \frac{\Sigma S_0 \times S1 \times \frac{m}{A}}{\Sigma S_0^2 \times \frac{m}{A}}$$

In which H = total unit stress in a member; S_0 = total stress in a member from vertical unit reaction only; S1 = total stress in a member from horizontal unit reaction; m = length of a member; and A = area of cross-section of a member. This formula was first presented by Professor Clerk Maxwell, and is used by Professor G. E. Greene for the determination of stresses in his text book on arches. For a long span this determination requires so many operations that it becomes very laborious, and in applying it to this case Mr. Theodore Cooper was convinced that it might be much simplified. A careful analysis demonstrated the correctness of this belief and by the application of the formula to two symmetrical panels, simple formulas were developed containing progressive factors which make it possible to write the formulas for any panel length and panel number after they have been developed for a given panel length and panel number.

The formulas were tabulated and applied, the computations made and the strain sheet prepared by Mr. Gunvald Aus and approved by Mr. Cooper. The development of the simplified formula and its application to this truss is clearly and concisely explained by Mr. Aus, as follows:

If in the truss shown in the figure, which is the simplest form of a spandrel arch, we assume a member A B of length m under a stress F to be shortened an amount dm, we know that the abutment O would have to move through a space ds, such motion being due to a rotation around panel point E, and, provided the motion is very small and no other members are strained and the other abutment remain fixed, we know that

$$\frac{ds}{dm} = \frac{y}{r} \text{ or } ds = \frac{y}{r}\ dm \ldots\ldots\ldots\ldots\ldots (1)$$

From the theory of elasticity we further know that

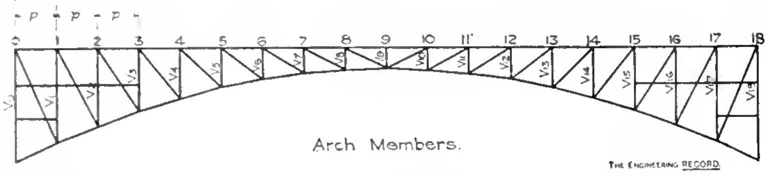
$$dm = \frac{m}{EA} \cdot F \ldots\ldots\ldots\ldots\ldots (2)$$

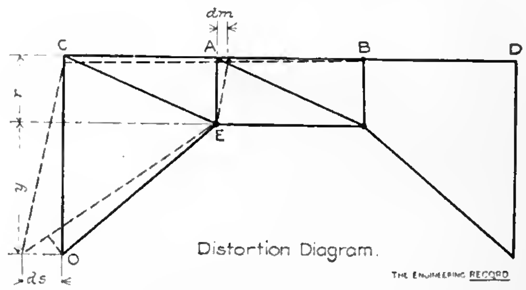
In which m, as already stated, is the length of AB; A the cross-section of the member, and E the elastic modulus.

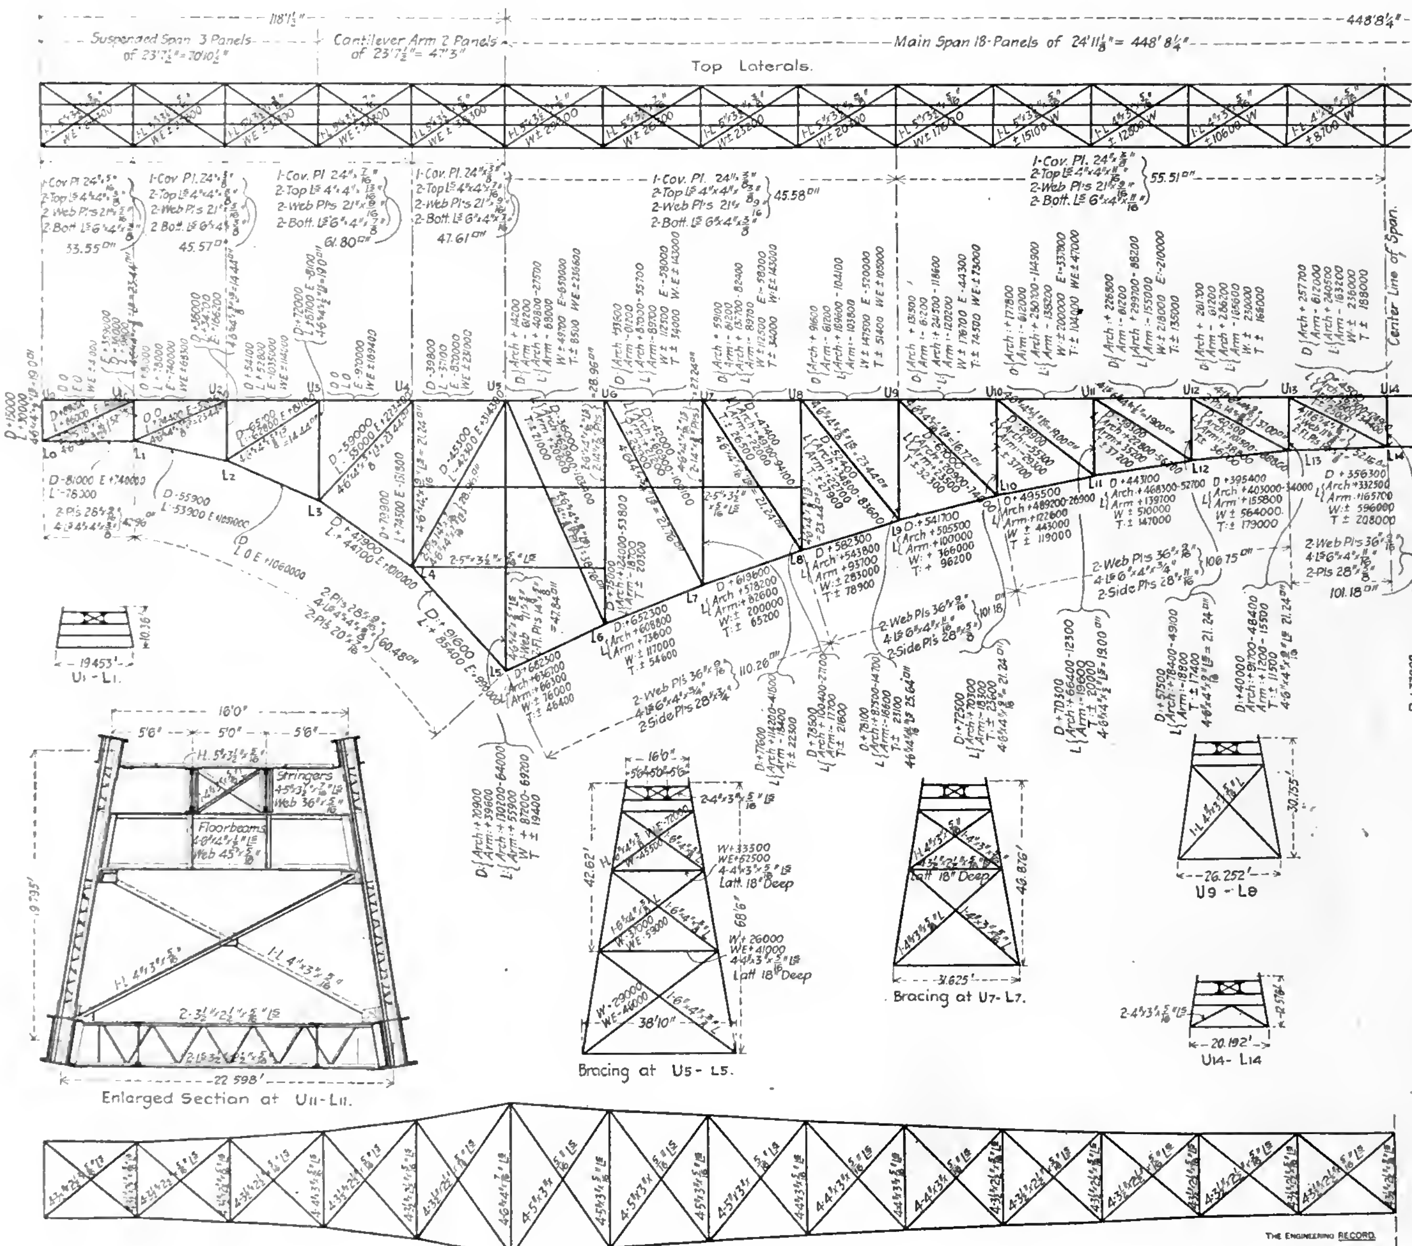
If we now further assume the stress F to be due to vertical and horizontal reactions v and h, we find that part of F due to v to be equal to $v\frac{x}{r}$, and the part due to h to be equal to $h\frac{y}{r}$, in other words:

$$F = v\frac{x}{r} + h\frac{y}{r},$$ and introducing this in equation (2) we get:

$$dm = \left(v\frac{x}{r} + h\frac{y}{r}\right)\frac{m}{EA} \ldots\ldots\ldots\ldots (3)$$







Bottom Laterals.

Strain Sheet and Material Diagram.

If we introduce this value of dm in equation (1) we find:

$$ds = \left(v \frac{x}{r} + h \frac{y}{r} \right) \frac{y}{r} \times \frac{m}{E A} \quad \ldots\ldots (4)$$

Evidently the expressions $\frac{x}{r}$ and $\frac{y}{r}$ are the stresses due to a vertical and a horizontal unit reaction, since such units would cause stresses $= 1 \times \frac{x}{r}$ and $1 \times \frac{y}{r}$, and for convenience we will call the former S_1 and the latter S_0, or $\frac{x}{r} = S_1$; $\frac{y}{r} = S_0$; we can then write equation (4) in the form:

$$ds = (v\, s_1 + h\, S_0)\, S_0 \frac{m}{E a} \text{ or}$$

$$ds = (v\, S_1\, S_0 + h\, S_0^2) \frac{m}{E a} \quad \ldots\ldots\ldots\ldots (5)$$

This equation holds good for any kind of truss, but applied to a spandrel arch where the abutments are fixed in a horizontal direction we know that $ds = O$, and therefore get

$$h\, S_0^2 \frac{m}{E a} = v \times S_1 \times S_0 \frac{m}{E a}, \text{ or}$$

$$h = \frac{v\, S_1\, S_0 \frac{m}{E a}}{S_0^2 \frac{m}{E a}}$$

That is to say, the stress F in a member AB produces a horizontal reaction expressed by this equation; or if we summarize the amounts of horizontal reaction produced by a stress F in each member of the truss to find the total horizontal reaction, we get:

$$H = \frac{\Sigma\, v\, S_1\, S_0 \frac{m}{E a}}{\Sigma\, S_0^2 \frac{m}{E a}} \quad \ldots\ldots\ldots\ldots\ldots\ldots (6)$$

As soon as we have the H for any given loading, the calculation of the stresses in the members is, of course, perfectly simple, either by graphical diagrams or by the methods of moments.

Professor Greene's method is to make a diagram for the stresses in each member of the truss, under a panel load applied to each panel, putting the resulting stresses $v\, S_1$ in the members in a table, and to construct a diagram for a unit horizontal reaction with the resulting stresses S_0 in another table.

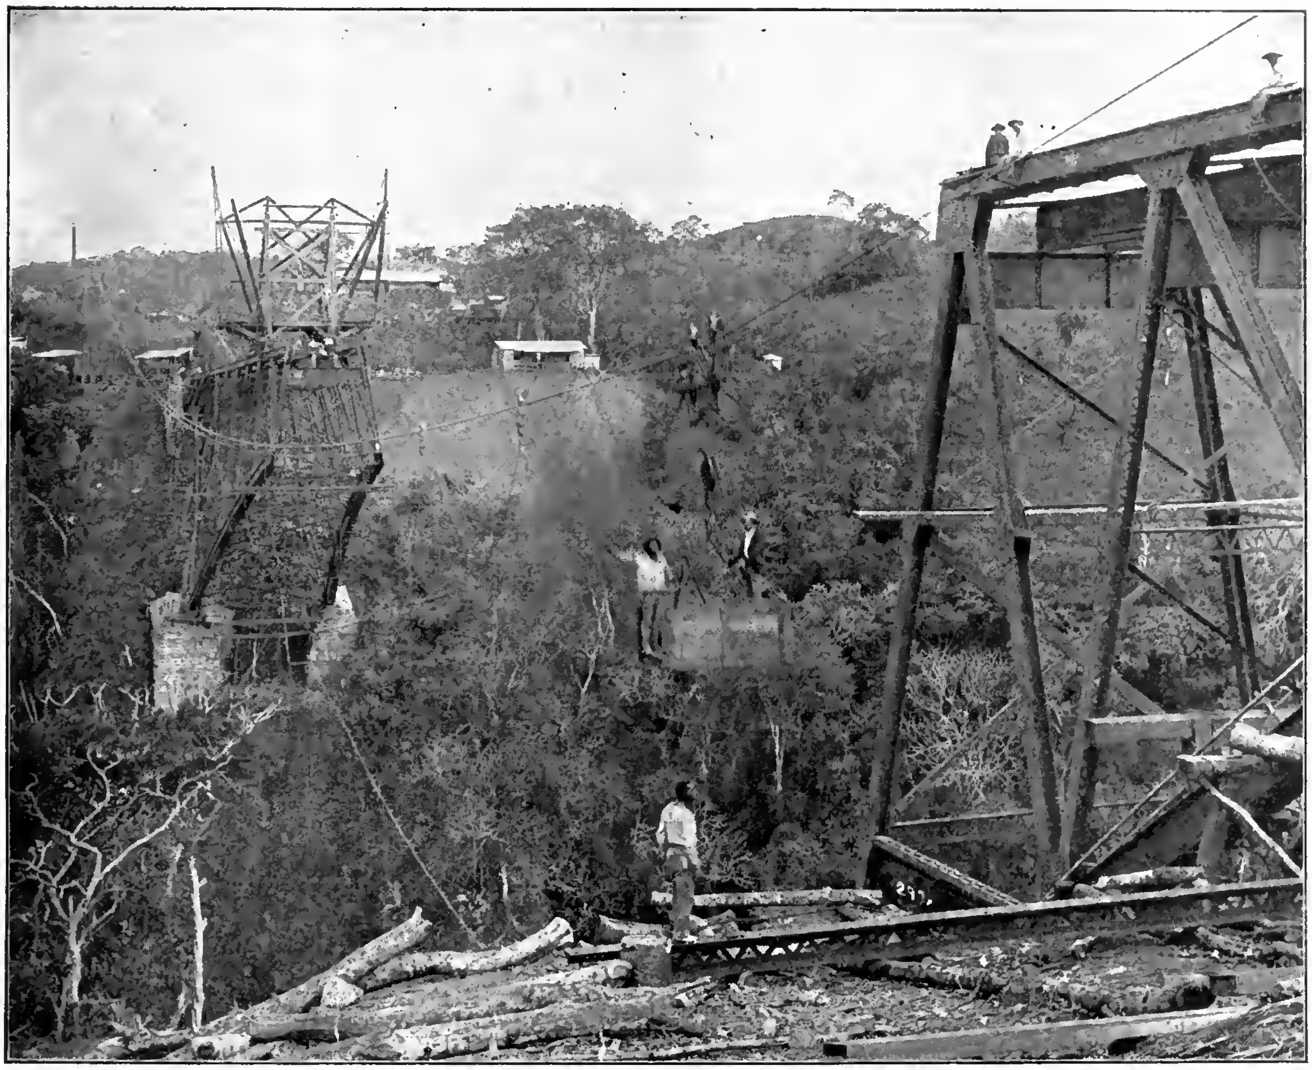
By multiplying and squaring the $h = \frac{v\, S_1\, S_0}{S_0^2}$ is now found, neglecting the $\frac{m}{E a}$ which has very little effect on the horizontal reaction.

By means of this approximately correct H, found by summarizing all the individual h's, he then calculates the stresses F in the members and proportions them for this approximately correct stress. He then introduces the cross-sections so found and the lengths of the members in equation (5) and again calculates the H which is now very nearly correct, and from this H again calculates the stresses F and proportions the members for the corrected stresses.

As already stated, it was a very tedious and trying operation to graphically construct the 18 diagrams needed for the Rio Grande bridge, and so Mr. Cooper suggested doing the operation by writing the formulas for S_0 and S_1 for a load on any panel point for two symmetrical members of the bridge and summarizing these formulas. The approximately correct $h = \frac{v\, S_0\, S_1}{S_0^2}$ could thus be written in very simple formula for each member and these formulas be very readily solved by logarithms or by Thatcher's Slide Rule. To make this method a little clearer, we will write the formula: $h = \frac{v\, S_0\, S_1}{S_0^2}$ for the first and the last panels of the top chord of the Rio Grande bridge for a panel load w on the first panel point. For these points the formula can be written $h = \frac{v\, S_1}{S_0}$.

We get for a load w on panel point 1, bearing in mind that the left reaction v is equal to $\frac{17}{18}$ w and that the right reaction is equal to $\frac{1}{18}$ w,

for member $0 - 1$, $S_1 = w \frac{17}{18} \times \frac{p}{v_1}$,
for member $17 - 18$, $S_1 = w \frac{1}{18} \times \frac{p}{v_1}$, and summarizing these two we get $w \frac{p}{v_1}$.



CABLEWAY AND TRAVELER USED FOR ERECTION OF RIO GRANDE BRIDGE ARCH.

We further get S_0 for each panel $= \frac{v_0 - v_1}{v_1}$ and for the two panels $= 2 \frac{(v_0 - v_1)}{v_1}$ and consequently

$$h = \frac{\frac{w\, p}{v_1}}{\frac{2\,(v_0 - v_1)}{v_1}} = \frac{w\, p}{2\,(v_0 - v_1)} \quad \ldots\ldots\ldots\ldots\ldots (1)$$

Exactly the same equation will be found for any other panels of the top chord for a panel load on (1) only. In exactly the same manner the formulas are written for all other loadings and for all other members of the truss. It will be found that it is only necessary to develop the formulas for one or two members for each loading, after which the others can be written out mechanically, as they have an easily established relation to one another.

An Economical Mill Engine.

Engineers who have followed the discussions regarding the use of high cylinder ratios for compound engines advocated for a number of years back by Mr. George I. Rockwood and have read in The Engineering Record of the excellent results obtained from several mill engines proportioned in accordance with his specifications will be interested to know that the high economy obtained at Grosvernordale, Conn., where a compound engine, when tested by Mr. George H. Barrus, developed a horse power with a consumption of 11.89 pounds of steam per hour, as described in our issue of November 20, 1897, has been lowered by more than half a pound by a compound engine built by the C. & G. Cooper Company, to Mr. Rockwood's specifications, for the Atlantic Mills at Providence, R. I. Three of the tests at the Atlantic Mills were made under different conditions as regards jacketing and the use of a reheating receiver. The fourth test included the efficiency of the boilers and gives the economy of the entire plant working under ordinary conditions. Mr. Barrus' report upon the engine was made to Mr. Thomas B. Owen, superintendent of the Atlantic Mills and to the C. & G. Cooper Company, of Mount Vernon, Ohio. Through the courtesy of these gentlemen, Mr. Barrus and Mr. Rockwood, the latter consulting engineer of the plant, The Engineering Record is enabled to print practically in full Mr. Barrus' report, which is, after being slightly changed for convenience in printing, as follows:

The accompanying tables give the data and results of the feed water tests of a 16 and 40x48-inch Cooper-Corliss engine, and coal test of the plant connected therewith, at the Atlantic Mills, which the writer made January 17 and 18, 1902.

In conjunction with Mr. George I. Rockwood, consulting engineer in charge of the design and erection of the plant, the writer made several preliminary feed water tests on the engines December 19 and 21, 1901. The final tests were conducted by the writer alone, Mr. Rockwood having unfortunately met with an accident that prevented his presence. These consisted of three feed-water tests; the first of which was made with the cylinder jackets and reheater coil shut off, the second, with the cylinder jackets and reheater coil in use in the customary manner, and the third, with the cylinder jackets shut off and the reheater coil alone in use. The first test extended from 7.45 to 11.45 A. M., the second from 1.30 to 5.30 P. M., and the third from 5.30 to 9.30 P. M. During the feed water tests, the steam was furnished to the engine, jackets and reheater from boilers Nos. 1 and 2 (the two boilers farthest from the engine room) fed with water from the weighing apparatus, which was supplied direct by means of the steam pump in the boiler room. The third boiler was run independently and used solely for supplying the steam in the mill for heating purposes and for running the auxiliaries, that is, the boiler feed pump, the air pump, the Webster heater pump, and the economizer engine. The No. 3 boiler was fed by the triplex power pump through the ordinary channels, the water being supplied to this pump from the economizer. The air pump during these tests exhausted into the Webster heater. The jacket water, which is ordinarily pumped into the boilers direct by means of the jacket pump, was discharged through a vent pipe attached to the jacket receiver, and passed through a surface condenser temporarily constructed, and thence into a barrel resting on scales, where it was weighed and then emptied and thrown away. During these tests, every precaution was taken to prevent accidental leakage of water or steam through drips or blow-offs, and the writer made sure by personal observation that all the water weighed entered the boilers, and that there was no leakage of steam from the plant save that recorded in the table, or elsewhere mentioned.

The coal test of the plant was made during the afternoon and evening of January 18, 1902, the time selected being Saturday afternoon after the usual "bell-time," when all the steam made could be used by the plant and none used for steam heating. The plant was run under the ordinary working conditions, with the exception that the steam exhausted from the air pump was utilized in the reheater, and thence in the low pressure cylinder, instead of being exhausted into the Webster heater, and used for heating feed water. In regard to this it may be said that the amount of steam used by the condenser, which, owing to the leaky condition of the packing rings in the steam pistons, was exceedingly wasteful, was too great to be utilized under the circumstances for heating the feed water; and it was concluded that the most economical method of using it would be to exhaust it into the reheater in the manner noted.

The steam was generated in Nos. 1 and 2 boilers, and that used by the auxiliaries was drawn from the low pressure pipe in the customary manner, this pipe being supplied through the reducing valve of No. 1 boiler. The No. 3 boiler (the one nearest the engine room), was shut

44. Equivalent evaporation into dry steam from and at 212° per pound of dry coal, as estimated, lbs.	11.34
45. Equivalent evaporation from and at 212° per pound of combustible, as estimated, lbs.	12.05

*It is estimated that the work done by the steam which enters the cylinders from the main steam pipe is 474.7 I. H. P., and the consumption of steam (including that used in the jackets) is 474.7x11.406 = 5,414 lbs. per hour. The steam used by the air pump on a supplementary test, including leakage of plant, etc., is 1341. lbs. per hour. The steam used for jacket pump, for the steam pump at the Webster heater, and for the economizer engine, etc., estimated at 3%, is 200 lbs. These three items aggregate 6,955 lbs.

Webster Heater Pump— 4½x3¾x4 inches.	
Jacket Pump— 4½x2¾x4 inches.	
Economizer Engine— 4x5 inches.	

The water supplied to the Webster heater is taken from the canal, and during cold weather has a temperature of about 40 degrees.

It is drawn from the heater by the 4½x3¾x4-inch pump, and discharged into the economizer under a pressure of about 80 pounds per square inch. The water leaving the economizer is in turn supplied to the triplex power pump which then forces it into the boilers. The exhaust steam from the Webster heater pump, the jacket pump and the economizer engine, all discharge into the Webster heater, and serve to heat the water before it is supplied to the economizer.

CONCLUSIONS.

It appears that the best results on the feed water tests were obtained when the cylinder jackets were shut off and the reheater coil alone was in use. This result was 11.22 pounds of steam per indicated horse power per hour, including that condensed in the reheater coil, no correction being made for the superheating at the throttle valve, which was 44 degrees.

When the jackets and reheater coil were both shut off, it appears that the feed water consumption was very nearly as low as the above, being 11.29 pounds per indicated horse power per hour, which goes to show that in the matter of steam consumption alone, the jacketing secured no material economy. The only advantage from the jackets in this case is that resulting from the slight economy due to returning to the boilers the jacket water, which has a temperature of 361 degrees, instead of feeding all of the water at 181.5 degrees, the temperature observed on the coal test, as also the mechanical advantage due to the extra power obtained under these circumstances from the low pressure cylinder.

The results of the coal test showed a consumption of 1.229 pounds of dry coal per indicated horse power per hour, this quantity covering not only that used by the engine itself, but also that used by all the auxiliaries concerned. This result is not quite as good as it would have been if the air pump had been in good condition. The writer's judgment is that the leakage of the air pump pistons caused an increase of the coal consumption amounting to between 3 and 4 per cent.

London's Water Consumption.

The water supply of London, England, is described in the 1901 report of the Local Government Board. The following data are taken from a summary of this part of the report as published in the "Journal of Gas Lighting." The total population supplied by the eight Metropolitan Water Companies on December 31 last was approximately 6,307,230, compared with 6,165,490 on the corresponding day in the previous year. The total average daily supply was 215,069,948 imperial gallons, representing a consumption of 34.49 imperial gallons per head, compared with 34.8 imperial gallons before. The sources of the supply were the Thames, the Lea, the springs in the valley of the latter river, and 39 wells in the chalk and sand formations. The volume of water delivered amounted to about 78,500,500,000 imperial gallons, 59 per cent. of which came from the Thames, 19 per cent. from the Lea, and 22 per cent. from springs and wells. Of the entire bulk of water coming down the Thames in August, 1901, 43.2 per cent. was withdrawn for the supply of London, whereas in April the quantity taken was only 5.6 per cent. With regard to the quality of the water supplied, the Thames and the Lea were generally favorable last year for the storage and filtration operations of the seven companies depending upon these sources, though, owing to floods in the early months of the year, the supplies of the Thames companies possessing the least storage showed considerable fluctuations in chemical quality during this period. Nevertheless, the river was in good condition for 311 days, and "exceptionally muddy and turbid" on 30 days only. Compared with the standard of 1,000—representing the mean amount of organic impurity in the Thames water delivered in 1868—the figures for the Thames and Lea respectively were 818 and 597, compared with 749 and 541 in the preceding twelve months. These figures show a slight inferiority in the year's supply, and it is pointed out that the organic matter present in the waters after undergoing the process of storage and filtration is to a relatively large extent of vegetable origin.

Sewage Farming appears to be a success with Mr. A. J. Dickinson, of Long Crendon, England, who stated at a recent meeting of the Association of Municipal and County Engineers that he had grown a crop of mangold wurzels of about 50 tons per acre, which would pay the whole cost of working, together with the interest on capital and repayment of loan.

Anchor Ice caused considerable trouble at the intake of the Detroit water-works last winter, according to the annual report of Engineer C. H. Hubbell. The supply is drawn from the Detroit River, and during the winter the usual protective covering of surface ice failed to form and twice the flow of water through all three intake pipes was entirely cut off by the accumulation of ice on the outer submerged cribs. In each case the difficulty lasted from about midnight to ten or eleven o'clock in the forenoon. During this period the only water entering the settling basin came through an emergency valve which had been built in the 72-inch intake pipe nearest the pier late in the fall. It was necessary to operate this valve at intervals of about twenty minutes in order to clear it of needle ice, which collected in large quantities. The supply procured in this manner, while not enough, was sufficient to keep the pumps running slowly and prevented the plant from shutting down altogether. The city was on short supply and considerable inconvenience was caused by the low pressure.

New Automatic Regulators for Septic Tanks and Contact Beds.

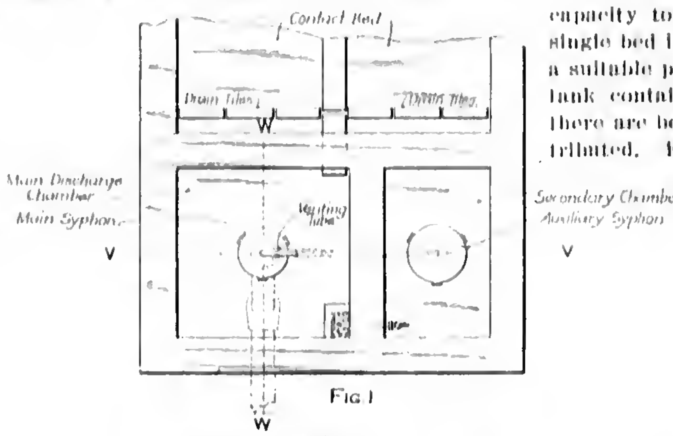
Two devices have recently been patented which deserve the careful consideration of those who have to deal with the regulation of septic tanks and contact beds. The first of these inventions, according to the letters patent, "relates to improvements in apparatus for intermittingly charging or discharging liquid tanks, and when employed for discharging tanks operates in such a manner as to permit the tank whose discharge is controlled thereby after being filled to remain filled for a certain determinate time before being emptied." It will be seen that this is particularly applicable to the conditions of a contact bed, allowing the bed to fill, stand full for any desired period, and then discharge automatically; but obviously the apparatus may be employed wherever it is desired to intermittently charge or discharge a tank of any description. The second invention "relates to an apparatus designed for intermittingly controlling the flow of liquid from a central tank or receptacle to a plurality of tanks or receptacles and so arranged that said plurality of receptacles may be filled or charged in predetermined rotative order from said main tank or receptacle." This invention was designed more especially for use in connection with a septic tank so as to receive the effluent from the tank and properly distribute it to contact or filter beds. The device for discharging the contact bed will be described first.

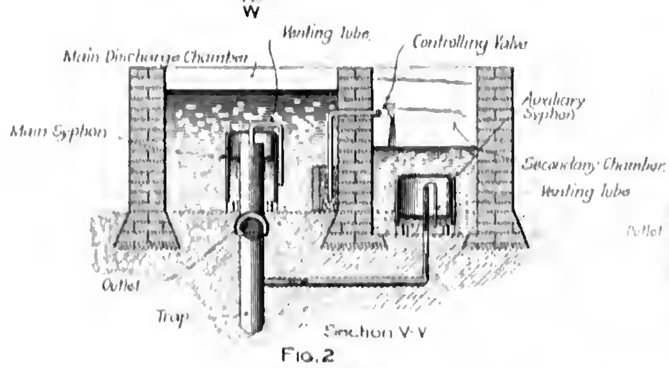
The accompanying illustrations show the general arrangement of the working parts, but some explanation is necessary for a full understanding of the operation of the apparatus. An ordinary drain pipe of convenient size connects the contact bed with a main discharge chamber, in which is located an automatic syphon. The longer leg of the syphon discharges into a U shaped trap connected to the outlet drain. A venting tube is provided, passing through the bell of the intake limb of the syphon and down into the discharge limb as shown.

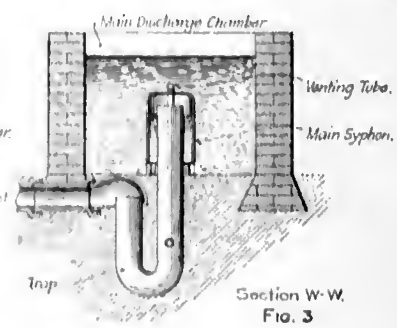
A short length of pipe with its inlet end protected by some filtering material, as shown in the cuts, connects the main discharge chamber with a secondary chamber, which chamber preferably has its bottom at a lower level than that of the other. This secondary chamber also contains a syphon. The bell or shorter leg of this syphon is made of greater diameter proportionately to the discharge limb than the bell of the main syphon. The lower end of the longer leg of the auxiliary syphon is extended and communicates with the longer end of the main discharge trap by means of a small pipe which enters the trap below the level of the discharge end of it. The venting tube of the secondary syphon has its shorter leg extending below the lower edge of the syphon bell. It is stated that this venting tube may be used in place of the one on the main syphon and vice versa.

A description of the action of the various parts follows. As the contact bed gradually fills with sewage the level of the liquid in the main discharge chamber also rises and at the same time the liquid rises in the bell or shorter leg of the syphon and compresses the air which is confined between it and the trap beyond. It is understood that when the contact bed and discharge chamber have become full the supply of liquid will be cut off, by automatic or other means, and the head due to this height of liquid will not be sufficient to cause the main discharge syphon to act. When the level of the liquid in the main chamber has reached the highest point of the pipe connecting it with the secondary chamber the latter will begin to slowly fill. As the connecting pipe is much smaller than the inlet pipe of the main chamber, and as the secondary chamber does not begin to fill till the other is nearly full, a much longer time is required to fill it than to fill the main one. The contact bed therefore remains full during the completion of the filling of the secondary chamber. The time required for filling the latter may be varied between wide limits by means of a valve or faucet on the connecting pipe.

As the liquid rises in the secondary chamber the air in the auxiliary syphon and the connecting pipe leading to the trap of the main syphon is compressed. This pressure continues until it is sufficient to overcome the pressure in the principal syphon, at which time the water which has been in the connecting pipe below the level of the trap outlet, is forced into the trap of the main syphon. When this happens the pressure in the auxiliary syphon is communicated to the principal syphon, and causes the water both in the trap and the bell of the main syphon to be depressed; the transmission of such pressure is continued until,







Device for Regulating Flow from Contact Beds.

combined with the pressure already existing in the longer leg of the principal syphon, it is sufficient to overcome the seal of the trap and start the main syphon in operation.

Thereafter the operation is like that of an ordinary syphon discharge, the syphon continuing its operation until the main chamber is emptied to the level of the mouth of the shorter leg of the syphon. Meanwhile the auxiliary syphon has been emptying its chamber. At the completion of the operation of both syphons the venting devices are brought into operation and the syphons completely vented, thus insuring a discharge at uniform intervals providing the inflow into the tank is uniform.

It will be noticed that just before the syphons begin to discharge, the level of the liquid in the shorter leg of the main syphon is lower than it was when the auxiliary syphon began to force the water out of the connecting pipe. This condition occurs because the pressure from the auxiliary syphon acts in both directions in the discharge limb of the main syphon. After the water in the trap has been depressed by the action of the main syphon below the level of the end of the connecting pipe, the pressure drives the water back a little way in the pipe toward the auxiliary syphon; but owing to the small size of the pipe and the consequent air friction, the air does not escape from the main syphon through the auxiliary one. A seal is therefore maintained in the connecting pipe which prevents the premature operation of the main syphon. Obviously the placing of the discharge end of this connecting pipe at a higher level than the end nearest the auxiliary syphon would accomplish the same result, even though a larger pipe be employed. The discharge leg of the auxiliary syphon will manifestly be made of such height above the connecting pipe that the column of water in it will give sufficient pressure to more than counterbalance the pressure produced in the main syphon by the head of water in the main discharge chamber.

Coming now to the other invention, that for discharging liquid from a septic tank into a series of contact beds for example, in regular order, it will be seen that the connections are necessarily somewhat more complicated than in the other invention, although the action is very similar.

A distributing or dosing tank of sufficient capacity to contain the desired charge for a single bed is connected with the septic tank by a suitable pipe or other connection. The dosing tank contains as many automatic syphons as there are beds to which the liquid is to be distributed. Four are shown in the illustration. The short leg of each syphon consists of a downwardly-opening bell, which may be supported on the upper edge of the longer leg. The longer leg of the syphon communicates with a trap leading to the outlet. In the distributing tank there is also a series of deep chambers or starting wells equal in number to the syphons. These chambers and their associated syphons will be referred to as Numbers 1 to 4 respectively as shown on the plan view. Within each of the wells is a downwardly-opening bell-shaped receptacle supported on short legs near the bottom.

Each syphon communicates with its associated starting well by a drain pipe passing through the top of the syphon. When any syphon begins to operate, the corresponding well is emptied through this drain pipe, as will be shown later. Freely connected with each chamber and below it, is a sub-chamber, into which the lower end of the drain pipe extends. The depth of this sub-chamber is made somewhat greater than the depth of the seal of the associated syphon, so as to insure a perfect seal at all times in the operation of the apparatus. Each of the bells in the starting wells communicates through a starting pipe with a syphon associated with another well of the series. Each of the starting pipes passes up through the open top of the well and thence laterally and downward toward the syphon with which it communicates, entering it below the seal-level as shown in the cuts, although that is stated not to be a necessity.

In the present instance the syphons and chambers are arranged in straight lines so that the starting pipe of chamber No. 4, which communicates with syphon No. 1, must pass from one end of the series to the other. They may, however, be arranged in circular series, in which case the starting pipes would all be of practically the same length.

In the usual working conditions, three of the starting wells are filled with liquid and one is empty, and all the extension chambers and the traps of all the syphons are filled. If it be assumed that the chambers No. 1, 2, and 3 be filled and chamber No. 4 be empty, the operation of the apparatus is as follows: The water entering the dosing tank from the septic tank fills the former to or above the tops of the starting wells. The traps at the discharge ends of the syphons are so proportioned with respect to the tank that the maximum head in the tank is not sufficient of itself to start the syphons into operation. When the dosing tank has been filled to the level of the tops of the starting wells the liquid begins to overflow into the empty well No. 4. The filling of this chamber causes the liquid to rise around the hollow bell in the chamber, and the pressure thus set up is communicated through the starting pipe to syphon No. 1, this pressure finally becoming great enough to overcome the seal in the trap and start syphon No. 1 into operation. This syphon continues in operation outwardly from the entrances to the main syphons. When the level of the liquid in the syphon trap has been depressed below the level of the entrance of the starting pipe, the pressure in the syphon acts to drive the liquid back into the vertical part of the pipe, so that the pipe must be proportioned so that this back pressure will produce a column of liquid in the vertical part of the pipe which will more than counterbalance the pressure in the syphon. When the starting well begins to fill, the air pressure in the hollow bell tends to overcome the pressure in the syphon and to force this column of liquid out of the starting pipe into the trap, and the continued pressure on the seal of the syphon trap finally forces the seal and starts the syphon.

It is desirable to provide vent pipes which communicate with the starting pipes just above the hollow bells and extend downwardly outside the bells. These vent pipes are provided to be sure that the bells and pipes are thoroughly vented after each operation of the associated syphon. The lower ends of these vent pipes determine the sealing levels of the several bells.

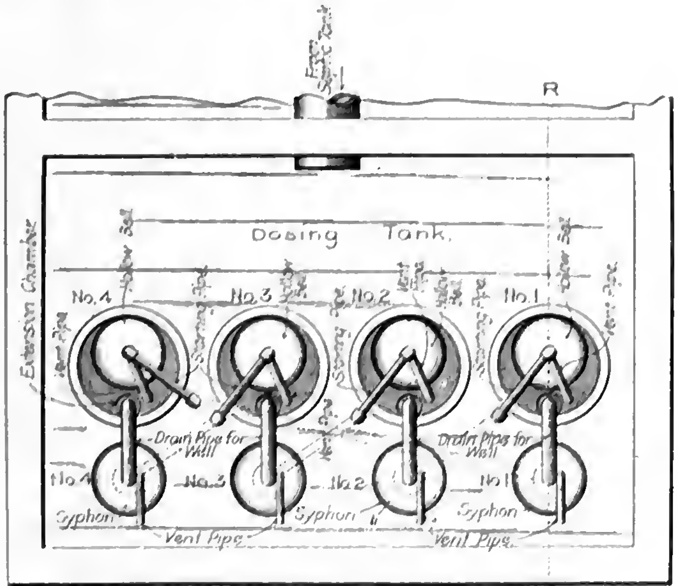


Fig 1

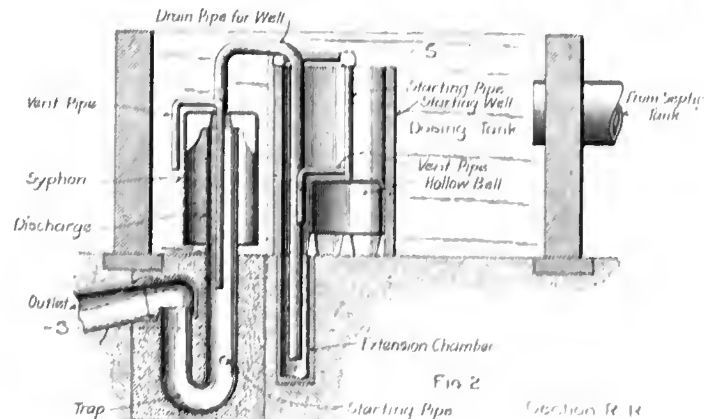

Fig 2

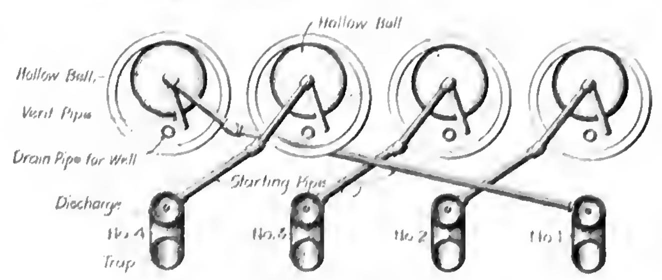

Fig. 3

Automatic Regulator for Discharging Septic Tank Effluent to Contact Beds.

until the whole dosing tank is emptied of its contents. At the same time a suction is produced in the drain pipe connecting this syphon with its associated well, so that No. 1 starting well is emptied through the drain pipe and the hollow bell in the chamber is freely vented.

After syphon No. 1 has stopped working, due to the emptying of the dosing tank, it is seen that No. 1 starting well is the only one empty, No. 4 having been filled by the overflowing liquid, and a similar round of operations will be gone through with in starting syphon No. 2. The reason that the wells which are already full do not cause the syphons with which they connect to operate, is that the hollow bell and starting pipe are also filled with liquid and can therefore communicate no air pressure to the traps of the syphons, as is the case when the empty well begins to fill.

Each of the small starting pipes is trapped at its entrance into the main syphon trap so as to prevent the escape of air from the syphon through the empty well. In the case shown in the illustrations these small pipes are trapped by merely laying them inclined downwardly and

It is stated that this invention may be used to advantage in connection with a double-trap syphon, by connecting the starting pipe to the blow-off trap. There being a less quantity of water to displace in order to force the seal, the starting chambers and bells may be made much smaller than in the previously described construction. Mr. S. W. Miller, of Chicago, of the Pacific Flush Tank Company, is the inventor of these devices.

The New England Water-Works Association will hold its next meeting in Boston on Wednesday, November 12. A paper on "Fuel and Its Economic Uses," will be presented by Prof. Ira N. Hollis, and a paper on "Waste Heat Engines" by Prof. Edward F. Miller. The election of officers will occur at this meeting. The following nominations have been made by the committee: President, Charles K. Walker, Manchester, N. H.; vice-presidents, V. C. Hastings, Concord, N. H.; George P. Wescott, Portland, Me.; Edwin C. Brooks, Cambridge, Mass.; E. W. Kent, Woonsocket, R. I.; H. N. Turner, St. Johnsbury, Vt.; J. C. Hammond, Jr., Rockville, Conn.; additional members of executive committee, P. Kieran, Fall River, Mass.; George A. Stacy, Marlboro, Mass.; H. G. Holden, Nashua, N. H.; secretary, Willard Kent, Narragansett Pier, R. I.; treasurer, L. M. Bancroft, Reading, Mass.; editor, Charles W. Sherman, Boston, Mass.; advertising agent, Robert J. Thomas, Lowell, Mass.; finance committee, E. J. Chadbourne, Wakefield, Mass.; W. F. Codd, Nantucket, Mass.; A. R. Hathaway, Springfield, Mass.

The Settling Basins at the St. Louis waterworks had deposited in them during the year ending April, 1902, 466,252 cubic yards of sediment, of which one-half was removed by manual labor at a cost of 1.017 cents per yard. Each of the six basins measures 672x400 feet. In his annual report, Commissioner Edward Flad describes the hydraulic dredge which was built for cleaning the basins while in regular use. A centrifugal pump, electrically driven, is mounted upon a barge, and is provided with a suction pipe which extends to the bottom of the basin and with a flexible floating discharge pipe which discharges over the side of the basin. The barge is 16x21 feet by 3 feet 9 inches deep and has a draft of about 26 inches. It is provided with a deck house, and is propelled across the basin by a hand winch operating on a stationary rope stretched for that purpose. The ultimate design contemplates a propelling arrangement electrically driven. The main pump is a 12-inch Morris centrifugal pump direct connected to a 90 horse-power motor. There is also a jet pump which furnishes a series of thirteen jets at the mouth of the suction pipe for dislodging the mud. This jet pump is a 4-inch Morris centrifugal pump, direct connected to a 20-horse-power motor. The suction pipe of the main pump is 12 inches in diameter and expands at its lower end into a flaring or fan-shaped mouth-piece, having an opening 10 feet wide and about 1½ inches high, and provided with rollers which rest on the concrete bottom. The floating discharge pipe consists of 21 sections, each 21½ feet long, connected by 3½ feet of rubber hose. The discharge pipe proper is 14 inches in diameter, and is supported by two floating air-tight pipes 12 inches in diameter, one on each side.

The Vitality of Sewage Bacteria in Soil and the Antagonism of Soil Bacteria to the Typhoid Bacillus.

A Review by G. C. Whipple.

The question of how long the bacillus of typhoid-fever is able to survive in various environments outside the body is one of great importance to sanitary engineers, and all data bearing upon the subject should receive serious consideration. Quite early in the history of bacteriology experiments were made to determine how long Bacillus typhi and its near relative, Bacillus coli communis, could exist in water and sewage, with the following general result: In ordinary drinking water which has been sterilized B. typhi does not multiply, but gradually loses its vitality until, after a period variously estimated from one to three months, it fails to respond to the usual tests and may be considered as dead. B. coli on the other hand does multiply if the amount of organic matter in the water is sufficient and may hold its vitality for nearly a year and perhaps for a longer period. The greater the amount of organic matter in the water, the longer will both germs survive provided the water be sterilized, but if it be not sterilized the antagonism of the ordinary water bacteria results sometimes in a speedy reduction in the number of B. typhi, and even in a material decrease of the more hardy B. coli.

During the last five years some extensive studies upon the viability of B. typhi in soils have been carried on by Dr. Sidney Martin for the Local Government Board of England, supplemented by studies of soil bacteria by his colleagues, Dr. A. C. Houston and Dr. E. Klein. These have been published as appendices to the annual reports of the Medical Officer to the Board since 1896-7. The thirtieth report of the Local Government Board for the year 1900-01, just issued, contains an interesting summary of the results as they stand to-day, together with detailed accounts of the latest experiments.

Dr. Martin's paper is on the "Nature of the Antagonism of the Soil to the Typhoid Bacillus." In summing up the results of his previous investigations he says: "First—In certain virgin soils, consisting chiefly of sand or peat, which have never been cultivated, the typhoid bacillus does not grow nor live under any condition of the soil, sterilized or unsterilized. Second—If these virgin soils are placed under cultivation, they become capable, when sterilized, of maintaining the typhoid bacillus for a certain limited period. Third—In cultivated soils, i. e., those containing organic matter, that have been sterilized, the bacillus lives for a prolonged period and spreads through the soil. If, however, the bacillus be added to a cultivated soil, sterilization of which has been omitted, the micro-organism cannot be obtained from such soil after twelve days or so."

The early experiments seemed to indicate that these results were due, not to any exhaustion of the nutritive quality of the soil as a medium owing to the rapid growth of the indigenous soil bacteria, but rather to a special antagonism of the chemical products of the soil-bacteria to the typhoid bacillus, and Dr. Martin set out to prove this by laboratory experiment. He first isolated from the soil a proteus-like bacterium, which he considered to be a typical form found in garden soil, and which he described under the name Bacillus ramificans. Three flasks were then prepared, each containing a three-quarter-inch layer of Chichester soil, moistened with distilled water and sterilized. To the first was added a few drops of a broth culture of the typhoid bacillus, to the second an equal amount of broth culture of B. ramificans, and to the third, equal amounts of broth cultures of both bacteria. At various intervals from 24 hours to 33 days, these soils were examined as to the relative number of bacteria in each. For 18 days the two species were present in the third flask in about equal numbers, but on the 26th day the B. ramificans greatly outnumbered the B. typhi, and on the 33d day no B. typhi could be found, while there was a copious growth of B. ramificans. Meanwhile both cultures incubated separately in the first two flasks were flourishing. The experiment was repeated with the same bacteria, using broth as a medium instead of moist soil. In this case the typhoid bacilli lived for 54 days, but disappeared before the 71st day.

In another experiment a 21-day-old broth culture of B. ramificans was filtered through a Chamberland filter, by which the bacteria were removed, the filtrate containing, however, the products of their growth. When this medium was subsequently inoculated with a culture of B. typhi, it was found that the bacillus died in less than fourteen days. This and other experiments fully described in the paper referred to demonstrated the existence of some chemical excretory product inimical to the life of the typhoid germ and produced abundantly by the common bacteria present in the soil.

To Dr. Martin's statement that the typhoid bacillus was destroyed in unsterilized cultivated soil in less than twelve days, bacteriologists naturally raise the point that only with the greatest difficulty can this bacillus be isolated from a mixed culture of bacteria such as would be found in the soil, and that the typhoid germ may have been present in his later cultures without being detected. His recent careful experiments seem to indicate, however, that his general conclusions above mentioned are substantially correct.

Recognizing the difficulty of separating the typhoid bacillus from mixed cultures Dr. Houston has approached the subject from another direction in a series of experiments described in a paper entitled the "Inoculation of Soil with Sewage." The object of his experiments was to ascertain whether certain easily recognized sewage microbes, such as B. coli, streptococci, and spores of B. enteritidis sporogenes, retained their vitality for any considerable length of time when sown broadcast on the soil.

A plot of ground, five feet square, upon which the soil was rather poor and which had received no fertilizer for six years, was treated at intervals with cesspool sewage, and samples of the surface soil were examined bacteriologically before treatment and again at regular intervals after treatment. The examinations included the determination of the total number of ærobic bacteria, the number of spores of ærobic bacteria, and tests for the presence of the above named species. On July 9, 1900, twelve gallons of sewage were applied. This sewage contained about two million bacteria per cubic centimeter and gave positive tests for B. coli, streptococci and B. enteritidis sporogenes. Two days after the application there was a decided increase in the number of bacteria in the soil, as many as 12 million per gram being found, but this was followed by a marked diminution, so that after 17 days the number was only about half a million. This decrease was accompanied by an increase in the ratio of spores to the total number of bacteria; in other words the vegetative forms decreased while the spores increased. Positive tests of B. coli were not obtained after the second day, but a form which agreed with the typical colon bacillus except that it did not produce indol persisted until the 24th day after the inoculation. Whether this form had been originally a typical B. coli and had gradually lost its power to produce indol, or whether it was a distinct variety and had been present all the time Dr. Houston was not able to determine. Streptococci did not persist beyond the second day, while the spores of B. enteritidis sporogenes persisted until the 24th day, when the experiment terminated. The same patch of soil was then watered bi-weekly in the same way from August 13 to September 22, after which samples were analyzed at intervals until December 13. The first sample taken after the application of sewage was stopped showed, as before, an increase in the number of bacteria to about 13 million per gram, but the number soon fell to about seven million per gram and remained constant at about that figure. A typical B. coli was isolated 31 days after the inoculation ceased, and for 80 days the degenerate form mentioned above could be easily observed. On the 80th day, though not on the intervening days, a true B. coli was found. Streptococci persisted only for two days, but the spores of B. enteritidis persisted until the experiment was discontinued. Dr. Houston's other experiments were made with London sewage applied to an urban soil, but the results did not differ materially from those already described. Dr. Houston's paper is voluminous in its detail, but in the light of American investigation his tests for the identification of B. coli seem entirely inadequate, but as he himself states, his errors are on the side of including among the members of the colon group forms which perhaps should not be so included. As the result of his investigation he concluded that "there was no indication that the addition of sewage to a soil leads to a marked or indeed to other than a temporary increase of the sewage microbes in general at the expense of the soil bacteria. On the contrary, the more hardy soil bacteria seemed to oust the more delicate sewage microbes in the struggle for existence." Dr. Houston's report is illustrated by many excellent photomicrographs of streptococci isolated from the soil.

Permits for Opening Streets to make connections with sewers are now issued by the Engineering Department in Grand Rapids, Mich., according to the latest report of City Engineer L. W. Anderson. This carries with it the inspection of all sewer connections within the street line and the replacing of all roadways and pavements. A uniform charge of $1 covers sewer permit and inspection. Heretofore the plumbers were given a permit at the office of the Board of Public Works, then secured a list of the locations from the engineering department, and made the connections where and in such manner as they saw fit. In the case of other permits, the actual cost of inspection is charged to and collected from the parties to whom the permit is issued.

The Reduction of Alumina to Metal is now progressing in America on what would have been regarded ten years ago as a stupendous scale. With 11,000 horse-power operating at Niagara Falls and 5,000 horse-power at Shawinigan Falls, in Quebec, America possesses 16,000 horse-power devoted to producing this metal. This will produce aluminum at the rate of 4,500 tons yearly, or a production twice as large as that of the rest of the world put together. Not only is this rate of production actually in force, but the same company has in contemplation the utilization of 12,000 horse-power additional at Massena, N. Y. The principal source of this production, according to a report by Professor Joseph W. Richards, chairman of the Committee on Metallurgy of the American Aluminum Association, recently abstracted in "The Iron Age," are the bauxite deposits of Arkansas and Georgia.

The Water Tower at Grand Rapids, Wis.

The water tower at Grand Rapids, Wis., consists of a covered steel tank, 26 feet in diameter with its top about 154 feet above the ground, supported on four columns resting on concrete foundation piers. These foundation piers are made of a 1:2:5 broken stone mixture, Portland cement being used. For the two upper courses of each pier four parts of broken stone were used instead of five. The concrete was mixed with a minimum of water, so as to make a moist, not wet, concrete. It was laid in 6-inch layers, and each foundation was completed in one continuous operation. In the upper courses special care was taken to secure a smooth surface, and to accomplish this, a 3-inch facing of mortar in the proportion of one of cement to two of sand was put in place together with the concrete. The anchor bolts for the tower posts were built into the foundations as the concrete was laid.

All the metal work in the tower, with the exception of the cast iron bolsters on the piers and other small details, is rolled steel, of medium grade, and made by the open-hearth process. The specifications stated that it should conform to the "Manufacturers' Standard Specifications for Structural Steel," as printed in the 1900 edition of the Carnegie Steel Company's handbook. The details of the four steel columns are shown in the accompanying illustrations. They are of the ordinary box column type with double lacing on the inside. The height of 116 feet up to the base of the tank is divided into four panels ranging from 34 to 25 feet each. At the bottom the posts are 48 feet apart center to center, and at the top 19 feet 9 inches. Access to the tank is gained by a series of bars 1¾x⅝ inch in section riveted at regular intervals to one of the columns.

The tank itself is 38 feet 3 inches high exclusive of the roof and the conical bottom, and is composed of eight rings of ¼-inch plates 5 feet wide, except the two bottom rings, in which the thickness of the metal varies from 5/16 to ¾ of an inch according to the location, whether close to one of the posts or not. The plates are riveted with lap joints, the four upper rings having only single lines of rivets. About 5 feet from the top a 5x3x⅜-inch angle is riveted around the outside of the tank to give it additional strength. The lowest ring of the tank, to which the conical bottom is attached, is composed of three thicknesses of plates, ¾-inch at the columns, then 9/16-inch, and midway between the columns the thickness is ⅝ of an inch. There are two 6x3½x⅜-inch angles riveted to the bottom of this ring, and these, reinforced with buttresses about 4½ feet high at each of the posts, rest directly on the tops of the latter. There is a single 6x3½x⅜-inch angle around the outside of the top of the lowest plates, connecting them to inside cover plates.

The conical bottom is simply riveted to the lowest ring of the tank proper about half way up, the top ring of the cone being bent to a 5-foot 8½-inch radius in order to make the connection. The cone has a vertical height of 16 feet, and is made in five rings, the upper one 5/16 of an inch thick and the others, ¼ of an inch. All the joints in the cone are double riveted. An iron ladder leads up the outside of the tank to a trap door in the roof.

The roof consists of a framework of steel covered with pine sheeting and tin. With the exception of a 1¼-inch vertical tie rod in the center, and the rafters, which are 4x5½-inch channels, the framework is composed almost entirely of 3½x3x¼-inch angle irons. The steel purlins of this same size have 2x2-inch pine strips bolted to them, to which the sheeting is nailed. The sheeting is of ¾-inch pine

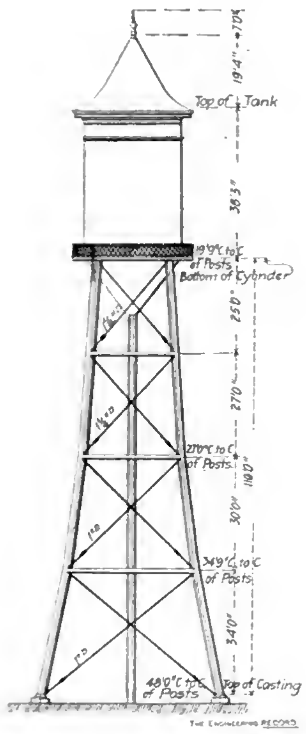
boards, cut segmentally and put on radially. A single thickness of building paper was then tacked over these boards and the tin roof put on with soldered horizontal joints and double locked radial joints. The tin was painted on the under side before it was placed on the roof. Surmounting the roof is a copper finial, connected to the steel framework by three connections of No. 2 copper wire, making electrically perfect connection. The height of the top of this finial above the bases of the columns is 173 feet 7 inches. A galvanized iron cornice finished off the roof at the bottom.

The inlet pipe is 12 inches in diameter, and connected to the bottom of the tank by means of a flanged expansion joint with iron body and brass sleeve. The cast iron base elbow of this pipe is set in 7 feet of earth on a concrete footing 3 feet square and 18 inches thick. A frost protection is built around the inlet pipe from the under side of the tank to the surface of the ground, and supported on a brick foundation extending to the concrete footing.

This frost protection is of woodwork as shown in the accompanying illustration, square in cross-section, and made by placing four



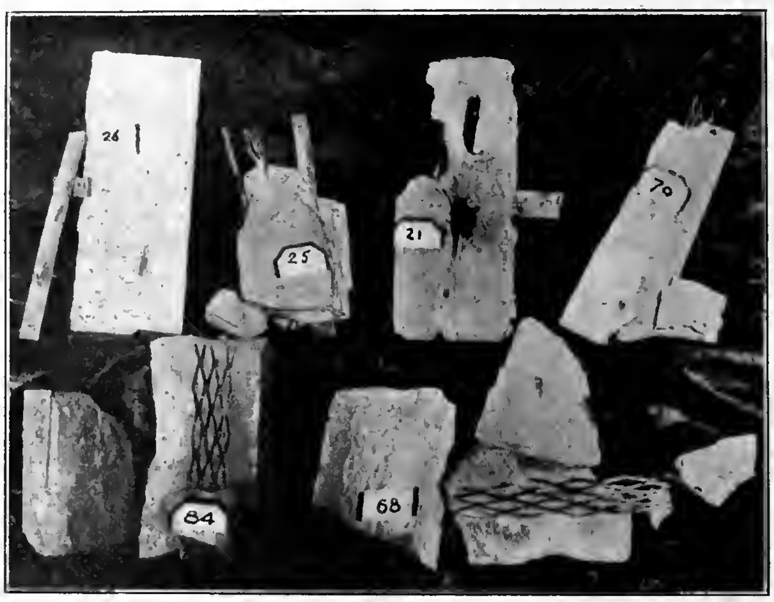
Elevation of Tower.

pieces of 4x4-inch lumber, halved diagonally, vertically against the pipe, and securing to these alternate layers of thin boards and building paper. There are first two thicknesses of boards and paper, and on the outside a double thickness of boards with paper between. These three courses are separated by ½-inch spaces made by ½x6-inch filling strips at the corners, and the vertical air spaces on each side are further divided by ½x6-inch fillers every 6 feet vertically, and fitting tightly against the corner pieces. All the corners are finished with ½x6-inch boards.

Before shipment to the work, all the steelwork of the tower was given a coat of boiled linseed oil, and after erection it was painted with two coats of graphite paint, the frost protection also receiving the same attention. The tank, however, was filled and tested for tightness before the final coat of paint was applied. The frost protection at the expansion joint and also at the ground was left open till after the final tests were made, in order to be sure that no leaks existed at those points. The engineers in charge of construction were Messrs. Loweth & Wolff of St. Paul.

Corrosion of Steel Frames of Buildings.

In the issue of The Engineering Record for September 20, 1902, there was published the results of an investigation by M. Breuillié on "The Durability of Steel in Concrete." Further information along this line is given in a recent report by Prof. Charles L. Norton, Massachusetts Institute of Technology, who is in charge of the laboratory of the Insurance Engineering Experiment Station, 31 Milk Street, Boston, of which Mr. Edward Atkinson is director. An abstract of the report is given below. The difficulty of cleaning the steel as done in the experimental work is so costly on the scale of practical building construction as to be prohibitive. It is true that structural steel is cleaned, but the result of the cleaning satisfies only a much less exacting definition of the term, clean, than that used in a laboratory. Protective coatings for steel are legion, and probably some of them would be effective if applied to the steel; but it has been the writer's common observation that the coating was put, to a large extent, upon rust, scale or foreign substances on the surface of the steel rather than upon the metal. The trouble is further increased by the fact that if the steel should be perfectly cleaned it would not remain cleaned long enough to be coated, by the usual commercial processes. Absolutely clean, bright steel will flash rust, when exposed to atmospheric moisture, almost as rapidly as powder will flash fire. It would seem then, that what the practical constructor needs to know is not alone, or so much, what happens to steel when cleaned and coated under laboratory conditions, but rather what befalls the steel as ordinarily manipulated in the operations at mill and shop and in building construction. The latter line of investigation, it is understood, the director of the Insurance Engineering Experiment Station hopes to undertake in the near future, and, in this undertaking, he invites engineers and architects to co-operate.



Steel Protected by Cement.

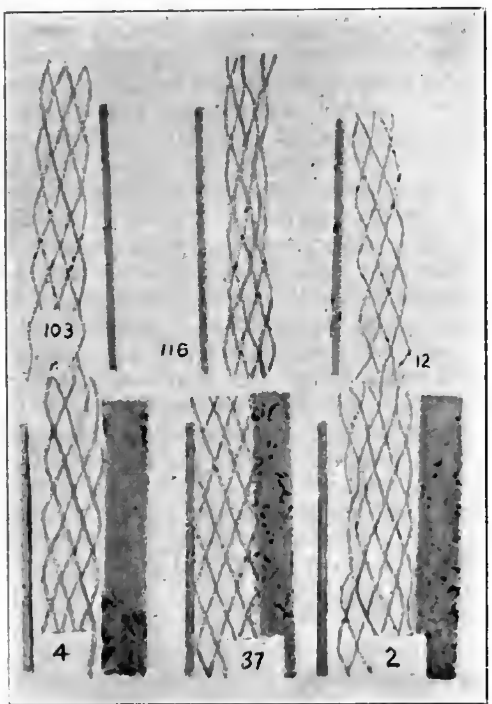
The problem of steel framing for a textile factory, bleachery or dyeworks, paper and pulp mill, and the protection of the metal from both heat and moisture, is a very much more difficult one than the construction of a department store or office building. The working of the fibers of cotton and wool requires a constant humidity at a rather high degree; the working of pulp and paper generate great volumes of vapor which must be guarded against.

The constantly increasing use of steel as a structural material in modern buildings has led to many questions as to its permanency. The examination of buildings ten to fifteen years old, when, during alterations, the steel framework has been exposed to view, reveals all stages and conditions of disintegration of the steel. So great has been the corrosion, even in this short time, in some cases, that a note of alarm has been sounded by some engineers most familiar with the subject. The use of steel beams and posts is of so recent date that no very exact deduction can be drawn as to the time required for a very serious or destructive loss of steel through corrosion; but surely, when a steel plate one-half inch in thickness loses more than one-eighth inch in five years, there arises a question as to the ability of the structure to last more than twenty-five years.

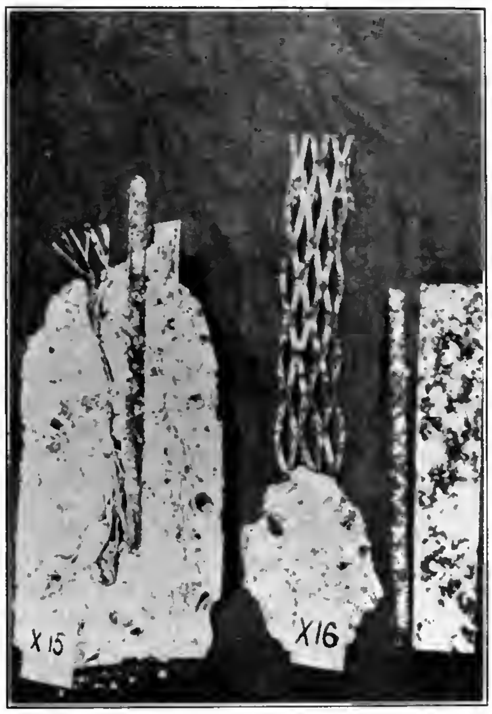
Some of the factors in the matter of corrosion of steel we know; others we do not know, and cannot until after a lapse of some years. There can be no question that moisture and carbon dioxide are the active agents in causing much of the rusting of steel. To what extent the two are relatively responsible and in what measure they need renewal, to keep up the process, is uncertain. It has been held that the formation of a coat of rust upon the surface of steel was the beginning of a progressive action whereby the rust, or iron oxide, acted as a continuous carrier of oxygen to the steel beneath. This process seems to require only moisture and atmospheric air containing carbon dioxide to start it, but as to the depth of penetration of the process, no assignable maximum in any given time is known. It is extremely probable that in a comparatively dry place the process is exceedingly slow.

There can, of course, be no question as to the ease of access to the steel, in many cases, of both moisture and carbon dioxide. When steel is bedded in the wall of the building, as is almost always the case, the changes in temperature from time to time, as well as the more or less constant difference in temperature between the two faces of the wall, tend to cause a condensation of moisture in the wall at different points. Further, the necessary carbon dioxide is most plentiful in the large cities, where the steel frame is most common. When the walls of the building are of brick or stone, moisture and carbon dioxide may enter at the joints and, to a greater or less extent, through the body of the stone or brick. Few stones are, however, porous to such an extent as to allow an appreciable penetration. Terra-cotta tile is of itself porous, and the existence of air passages tends to increase the condensation of moisture and its absorption by the terra-cotta and possible contact with the steel. Concrete, made of Portland cement with sand and either cinders or stone, would seem to offer more protection to the steel than any of the materials just mentioned; yet, we hear from time to time of the loss, by corrosion, of steel bedded in concrete.

It has been held by several engineers that the mere alkaline nature of Portland cement was a sufficient guarantee of its protecting steel from rusting. There is, of course, good chemical reasoning for this, the familiar use of strong alkaline solution in boilers to prevent the formation of scale being based upon the same principle. This would seem to settle the matter once and for all, were it not a fact that steel bedded in concrete has corroded very rapidly, while other steel in a different concrete of the same kind of cement stands without change for ten years or more. An examination of several cases where expanded metal had been embedded in concrete showed plainly that wherever the steel was exposed through cracking rusting began, even though the cracks were very fine. It would seem that the alkaline nature of the cement would be sufficient to prevent corrosive action occurring within a few hundredths of an inch on the moist surface of the steel, but such is not always the case. To study the matter systematically, two brands of American Portland cement (Alpha and Lehigh) were selected; two kinds of cinders, one from a sugar refinery, the other from Boston and Albany locomotives; a sharp, clean beach sand; and a hard, clean broken stone, the larger part being fragments of flint and trap rock. Concretes were made up in bricks about 3x3x8 inches, with the steel specimens near the center.



Steel Rusted at Voids in Concrete.



Steel Rusted by Contact with Cinders.

The following mixtures were tried at first: Neat cement; cement, one part, to three of sand; one cement to five broken stone; and one cement to seven cinders. All briquettes were made in duplicate with both cements. There were later made up briquettes of one part cement, two sand and five cinders, and of one cement, two sand and five crushed stone.

It was hoped to vary the density, the porosity and the nature of the contact with the steel, as well as the chemical composition of the concretes. The cements were tested chemically and physically and found good. The cinders, when washed down with a hose stream and dried, tested distinctly alkaline, and analysis revealed very small amounts of sulphur. The stone and sand were thoroughly washed and clean. The ingredients were mixed dry in every case and, when wet, thoroughly mixed and tamped until wet on top.

The cleaning of the steel was the most troublesome problem met with. It was necessary to scour the pieces, then pickle in hot dilute sulphuric acid, and finally dip into hot milk of lime. When cold, the lime was removed with a wire brush. This left the steel clean and bright, ready to be put into the test bricks. The specimens used were a mild steel rod 6 inches long and ¼ inch in diameter, a piece of soft sheet steel 6x1x1/32 inches and a strip of expanded metal 6x1 inches, all three pieces being put in each brick. Since time would not permit of exposing these specimens to natural conditions, they were enclosed in several large tin boxes, sealed tightly, and subjected, one-quarter of them to an atmosphere of steam, air and carbon dioxide, and a second quarter to air and steam, a third to air and carbon dioxide, and a fourth stood upon the table of the room, with no special care as to their temperature or dryness. Of the entire number, about one-half were set in water for one day, the rest for seven days, before sealing up.

At the end of three weeks the briquettes were carefully cut open and the steel examined and compared with specimens which had lain unprotected in each of the tin boxes. The neat cement specimen can be dismissed without discussion, for the protection was perfect. The steel was as bright as when put in. The unprotected pieces were found to consist of rather more rust than steel. The steel was wrapped about pieces of uralite, to serve as a means of identifying it by number, the stamped numbers being nearly obliterated by the rust. Of the remaining specimens, hardly one had escaped serious corrosion. The location of the rust spot was invariably coincident with either a void in the concrete or a badly rusted cinder. In the more porous mixtures, the steel was spotted with alternate bright and badly rusted areas, each clearly defined. In both the solid and the porous cinder concretes, many rust spots were found, except where the concrete had been mixed very wet, in which case the watery cement had coated nearly the whole of the steel, like a paint, and protected it. Some briquettes made later of finely ground cinders and cement, in varying proportions, when exposed to moisture and carbonic acid, showed how effectually the presence of cement prevented rusting, even in a highly porous mass—one cement to ten of cinder, provided there were no cracks or crevices or distinct voids.

From the examination of these several hundred briquettes there have been drawn several conclusions: First: Neat Portland cement, even in thin layers, is an effective preventive of rusting. Second: Concretes, to be effective in preventing rust, must be dense and without voids or cracks. They should be mixed quite wet where applied to the metal. Third: The corrosion found in cinder concrete is mainly due to the iron oxide, or rust, in the cinders and not to the sulphur. Fourth: Cinder concrete, if free from voids and well rammed when wet, is about as effective as stone concrete in protecting steel. Fifth: It is of the utmost importance that the steel be clean when bedded in concrete. Scraping, pickling, a sand blast and lime should be used, if necessary, to have the metal clean when built into a wall.

The Artesian Water Supply of Long Eaton, England.

Until about ten years ago the residents of Long Eaton, England, derived their water supply from individual wells, and as the population was rapidly increasing (being about 10,000 in 1893), and no sewerage facilities whatever were afforded until after the wells had become badly polluted, some other source of supply was a necessity. In the fall of 1888, a company was formed which, without consulting the local board, proposed to secure the monopoly of the water supply of the district from wells driven in the vicinity. Mr. George Hodson, M. Inst. C. E., who was retained by the local board to report upon this scheme, concluded after investigation that the proposed supply would be both insufficient in quantity and undesirable in quality, which opinion was concurred in later by other prominent engineers. The company ultimately abandoned all attempts to utilize its supply so far as Long Eaton was concerned. Meanwhile a careful physical and geological examination was made of the entire available district, comprising about 120 square miles. The progress of this investigation and a description of the works finally built were presented in a paper read by Mr. Hodson before the Incorporated Association of Municipal and County Engineers from which the following notes have been taken:

All possible sources of supply were investigated, and as soon as it became evident that an underground supply was all that was available, the question as to where the wells should be located became a vital one, specially difficult to decide on account of the geological conditions encountered. The water present in the gravel underlying the immediate neighborhood of the town, in addition to being nearly as badly polluted as that in any of the rivers flowing through the section, was limited in quantity because of impervious underground ridges that divided the gathering ground into small sections.

In order to satisfy some members of the local board that a suitable supply could not be obtained from the immediate vicinity of the town, a well was sunk to a depth of 165 feet through the gravel and the underlying marl. The yield of water obtained at this depth was insufficient to supply the pump for more than a few minutes at a time and analysis showed it to be a "nearly saturated solution of sulphate of lime."

Wells sunk in the vicinity of Weston, about two miles from the place finally selected, revealed various geological errors in the ordnance map of that district, but no satisfactory supply of water. Careful examination led to the belief that all the conditions for an artesian supply were present further west, and borings were made at the Stanton Barn site near the town of Melbourne. Here a layer of impervious sandstone was found to extend to a depth of 60 feet, and then to a depth of 190 feet the boring passed through shales and clays. At this depth the water began to overflow freely at the surface, and at 220 feet, after passing through a layer of hard sandstone, a fissure was struck which sent up the water with such force that the 2½-inch hole yielded 150,000 imperial gallons per day, and fragments of rock were thrown up into the air. When the pipes were carried up from the casing tubes the water rose 35 feet above the surface of the ground, and might have risen higher had it been worth while to make a water-tight joint. Analyses of the water both from the upper and lower rock proved it to be of very satisfactory quality, the deep water being slightly the harder.

The site of the well possesses all the features essential to the success of a water works system. It commands an ample collecting area, free from any danger of pollution so far as could be foreseen. It is in the direct dip of the strata and cannot be very well interfered with by rival works. It is close to a good public road, and within reach both of a railroad and a canal for the conveyance of coal. Moreover, it possesses the advantage that the nearest road for the pumping main passes close to the town of Melbourne and through the town of Castle Donington, where, within 300 yards of the direct route of the pipes, there is a suitable site for a reservoir 312 feet above the market place in Long Eaton.

The contract for building the works, although let to one firm, Messrs. Price & Shardlow, Nottingham, was divided into two parts, one for sinking and proving the yield of the well and the other for providing and laying all the mains, hydrants, etc., building the reservoir and pumping station, and providing and setting the machinery.

The main well, 11 feet in diameter, was begun a few yards distant from the overflowing test well. It was carried down 70 feet, so as to pass through the upper rock and 10 feet into the shale beneath. This last 10 feet was lined with 18 inches of brickwork and had a brick floor. Two main headings with numerous branches were driven from the well, commencing at the level of the base of the hard rock.

The contractor provided a temporary pumping plant capable of handling 60,000 imperial gallons per hour. It consisted of three Cornish boilers, supplying steam to a pair of No. 10 "aqua-thruster" pumps, together capable of pumping the required quantity. These pumps were slung from the square framing of the well in such a manner as to be easily raised or lowered, or withdrawn altogether whenever necessary. The winding engine was supplied with steam from the same boilers, and a Root blower was provided for ventilating the headings, being worked by an engine attached to a portable mortar mill. The boilers were set in brickwork, the bricks being subsequently used in the foundations for the permanent machinery.

The water pumped was measured by means of a weir and an automatic recording device. The quantity steadily increased with the progress of the headings, ultimately reaching 880,000 imperial gallons per day including the deep supply. The Root blower used for ventilation proved effective until the headings had been driven about 100 yards in each direction. After this distance had been reached considerable hindrance was caused by the delay in removing the fumes created in the blasting operations, and to facilitate the work the contractors found it to their interest to put down 6-inch borings from the surface to aid the blower. Each of these holes, owing to the heat from the steam used by the pumps in the well, became down-cast shafts, and not only rapidly cleared away the dynamite fumes, but also kept the headings cool and pleasant to work in. After the completion of the well these ventilation holes were made secure at the bottom by oak plugs and filled with Portland cement grout.

The headings were about 6 feet high and 5½ feet wide, this being found the most convenient size for two men to work comfortably at a face. They were given a gradient of 1 in 500, and as the work advanced, portions were widened out at intervals to serve as turn-outs for the cars. It was found necessary to extend the headings to a total length of 2,250 feet, much further than was expected, on account of the fissures in the rock being filled with finely divided clay, which considerably hindered the circulation of the underground water. This condition, which it was impossible to have foreseen, illustrates some of the uncertainties of an underground supply. However, it is considered probable that in a case like this the yield will increase rather than decrease with age due to the clay being washed out of the fissures to some extent.

The time occupied in driving the headings was 38 weeks and the average rate of progress varied from 30.16 to 16.3 feet, the mean being 26.93 feet per face per week. There were always two faces being driven at the same time, and three faces for a short period. Most of the holes were drilled with ordinary hand drills, but in the softer rock ratchet drilling machines were used. Gelignite was almost the only explosive used until the last few weeks, when it was replaced entirely by the more expensive gelatine dynamite, which is much more powerful in its action and gave better results, especially in the tougher rock. Generally three holes were put in a face and fired simultaneously.

During the time the headings were in progress, the original well was widened out to 10 inches diameter and was cased with steel tubes perforated where they passed through water-bearing beds. This well yielded 281,000 gallons of water, and a second, also 10 inches in diameter, was carried down to the bottom rock about 150 feet away. The well sinking proved that a fault of 10 feet throw existed between the original boring and the main well, and it was found that although the second boring yielded 135,000 gallons per day from the middle rock, that the source from the bottom rock was completely cut off and not a drop of water could be obtained from it.

The water from the deep wells is slightly harder than that from the headings and as the total quantity was much in excess of the demand, it was decided to reserve this supply for emergencies. A special valve was therefore provided, by which it could be regulated from the surface. The cast-iron base plate for this valve is 3 feet in diameter and is securely bolted to the rock at the level of the headings, the joint being made watertight by a sheet of gutta-percha. A guide tube is carried down from the surface to the headings, of sufficient diameter to allow the valve to be entirely withdrawn. The long valve rod is worked by a screw passing through the pedestal at the surface, having an indicator attached which shows the position of the valve. The valve proper is coned at the top and bottom, and constructed so that it descends freely upon its seat, being bushed with gunmetal on both faces and ground watertight.

Among the residents of Melbourne it was freely alleged that the supply met with was being drawn from the River Trent, instead of being water absorbed upon the higher ground, and to dispel this belief one of the ventilating holes was left open after the completion of the headings and before the permanent pumps were started. Although the deep well valves were kept closed, the water gradually rose until it overflowed from the hole and passed away into the Trent at a point 12 feet below its point of issue.

The machinery at the pumping station consists of four deep well pumps 14½ inches in diameter and four surface pumps, driven by spur gearing from two compound tandem surface condensing engines with 11½-inch high pressure cylinders, 20-inch low pressure cylinders and 32-inch stroke. The engines are supplied with steam by two Lancashire boilers 6 feet 3 inches in diameter and 20 feet long, with a working pressure of 105 pounds per square inch. When working together at normal speed the load is equivalent to 120 pump horse-power. The well pumps deliver the water through the surface condensers into tanks outside the engine house, from which it is drawn by the four 10-inch horizontal double acting pumps which force it to the reservoir. Each pair of well pumps and horizontal pumps is connected to the same crank in such a manner that the well pumps are doing their maximum duty while the force pumps are at the minimum, which arrangement results in very smooth running. The machinery is in duplicate in every part, and can be worked independently. Its contract capacity was 56,000 imperial gallons per hour, but it is stated that it will easily pump 60,000 gallons.

Municipal Ice-Making is leading to legal complications in Wolverhampton, England, according to "The Surveyor." It seems that a local ice merchant and the corporation, which conducts a cold storage and ice factory, are competing in their retail prices of ice to the public, and that the corporation has undercut the dealer's quotation for ice. The merchant has now appealed to the Local Government Board as to the legality of the corporation manufacturing ice for sale to the general public.

The Reconstruction of an Arched Culvert in Grand Rapids, Mich., is described substantially as follows in the 1901-2 report of City Engineer L. W. Anderson: The old culvert consisted of a semi-circular stone arch, 10-foot span, with an invert of 3-inch planking. The length of the arch was 65 feet, and it consisted of simply a 12-inch ring without backing. It had entirely broken away at one end and the planks were supported at the ends only, the ordinary flow of the stream passing under them. Concrete abutments were constructed under the arch down to rock, the planking being cut away a section at a time; the arch was backed up with concrete and the top plastered with Portland cement mortar; a 4-inch brick arch was built inside of the old arch to protect it from further disintegration.

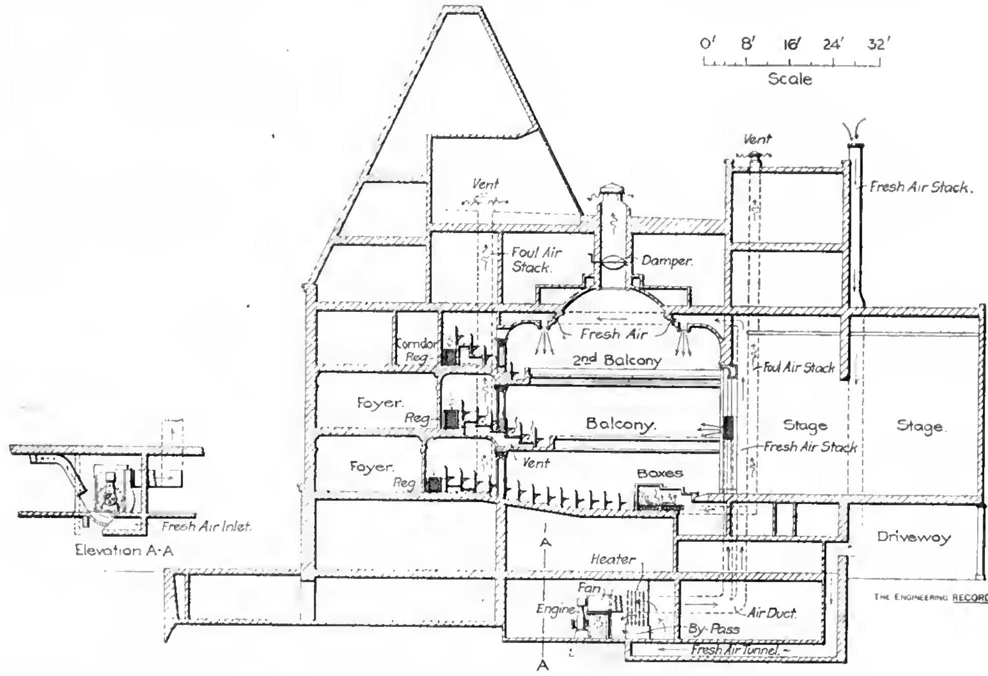
Power and Ventilation in the Bush Temple of Music, Chicago.

The heirs of the late William H. Bush, one of the pioneers of Chicago, have recently erected a large building of beautiful design on the corner of North Clark Street and Chicago Avenue, known as the Bush Temple of Music. The architecture is of the French Renaissance style with a French Gothic roof crowning the main pavilion. A view of the exterior is shown in an accompanying reproduction of the architect's perspective. The main feature of the building is its large, centrally located auditorium, rising through the second, third and fourth stories, around which are located various studios and offices. Most of the main floor and a part of the second are occupied by offices and salesrooms. The office portion of the fourth floor is given up entirely to the Railway Department of the Chicago Branch of the International Correspondence Schools and the basement contains a restaurant and barber shop. Above the auditorium are three smaller recital halls with adjoining parlors and retiring rooms.

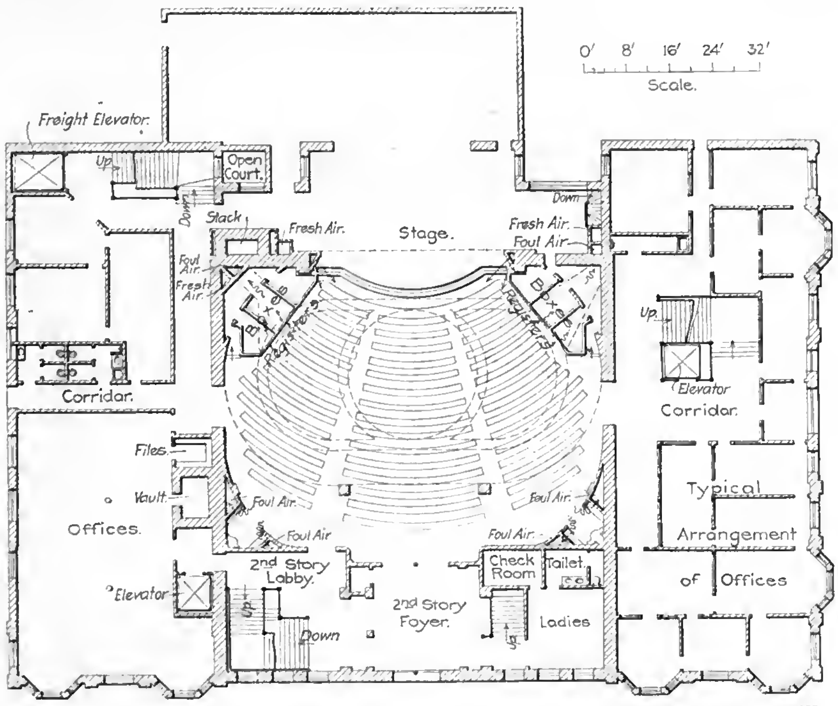
Bush Temple of Music, Chicago.

The mechanical plant, located at the west end of the basement, is very complete for a building of this size and is compactly and conveniently arranged as shown in the accompanying basement plan. The steam is generated by three Scotch marine boilers, 78 inches in diameter and 14 feet long having a rated capacity of 80 horse-power each. These supply the several engines and the heating system when necessary. The electricity for power and lighting purposes is supplied by two 60-kilowatt, 125-volt, direct-current, compound-wound generators of the Northern type, direct-connected to two 12x13-inch simple engines, made by the Ball Engine Company, of Erie, Pa. Of the other engines, two are for driving ventilating fans and one for compressing air. One of the uses to which the compressed air is put is to operate air-brake models for a 60-car freight train and a 5-car passenger train in the Correspondence School. All other machinery is motor driven; two motors, of the Northern type, run two Yeomans bilge pumps of a capacity of 400 gallons a minute and a 16-horse-power Holtzer-Cabot motor is belted to a Kroeschell ice machine, operated on the carbonic anhydride system and having a capacity of 6 tons of ice a day. This ice machine, besides supplying ice for the café in the basement, is also used to cool the distilled drinking water, which is pumped to all parts of the building. Three electric elevators of the Eaton & Prince make are installed, each operated by 20-horse-power motors. Two of these are for passengers and one is for freight. An organ in the auditorium is pumped by a 5-horse-power motor-driven fan and the keyboard controls the pipes electrically, the current being supplied by a two-cell storage battery.

There are two separate ventilating systems, one for the auditorium and one for the restaurant in the basement, each with its own plenum fan. The latter, as indicated in the basement plan, is a combination plenum and exhaust system, as the fresh air is forced into the room by a blast fan, which takes its air through tempering coils, and the vitiated air is removed by an exhaust fan at the base of a discharge shaft. The basement ventilation is equipped with an unusually large number of registers; there are 70 for delivering air, placed 7 feet above the floor level, and 37 for discharging it, placed 8 inches above the floor. The latter have an opening of 6x28 inches each and the velocity through them is about 280 feet per minute. This allows a change of air in the room once in every eight minutes. In all other respects it is the same in principle as the larger system for the auditorium ventilation.



Sectional Elevation of the Building.



Main Floor Plan of Auditorium.

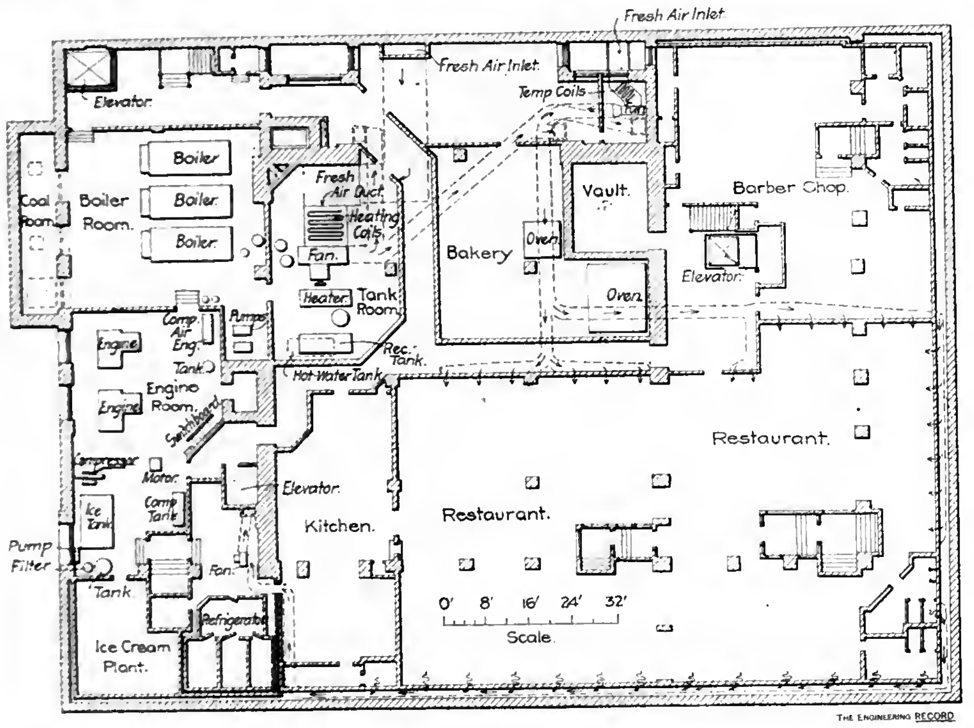
The ventilating and heating of the auditorium is, perhaps, the most interesting feature of the equipment. The heating and ventilating are combined by the use of the indirect system whereby warm fresh air is supplied to replace the foul air. The downward method of distribution in the hall is adopted. The objection frequently made against the downward system, on the ground that it is less effective than the upward system in keeping the air pure for the same volume replaced in a given time, was met by using a large amount of air and the designers say that the system has improved, instead of detracting from, the acoustic properties of the hall. For the sake of the acoustics of the hall, all draperies, upholsteries, and other non-resilient materials were avoided where possible, but incidentally, the assistance they would render by virtue of their properties of retaining warmth and excluding cold were lost. The air thus encounters hard surfaces almost entirely and this with many places of admitting cold air, such as several foyers and the proximity of an open-air balcony or promenade, made the problem of efficient heating somewhat difficult.

The fan and heating coils are located in the basement and the fresh air is drawn in through a horizontal underground tunnel which connects with a steel shaft dropping vertically on the outside of the building from a point above the roof. The fan is an 8-foot double discharge Buffalo Forge Company's steel plate fan, having a blast wheel 85 inches in diameter and driven by a vertical engine, of the same firm's make, direct-connected to the fan shaft. The air is taken through the usual heater coils of staggered pipes consisting of six two-row sections. Each section has its own steam and drip connections to cut out one or more sections in moderate weather and, of course, preventing an entire shut-down should one become disabled. The coils contain 5,000 feet of 1-inch pipe, equivalent to 1,670 square feet of surface, and are encased in an extra heavy steel plate housing, to give an absolutely tight connection from fan inlet to the outdoor air supply. The housing has doors which render the coils accessible for repairs or inspection. Below the coils there is a by-pass controlled by a damper, which may be opened wide in summer time to avoid retarding the air by the pipes in the coils when the latter are not in use, or may be partly opened in winter to regulate the temperature by a mixture. This temperature is usually maintained at from 130 degrees to 170 degrees as circumstances require.

ium. The foul air is removed through registers in the private boxes, under the seats of the balcony, in the rear of the gallery and the rear and sides of the main floor, and finally passes out through the roof by means of tile and galvanized iron stacks with siphon ventilators at their tops. The current through these stacks is dependent, largely, on the pressure of the fresh air driven into the auditorium by the fan, augmented by the chimney action of the flues. The accompanying transverse section of the building indicates the method of circulating the air through the theatre.

The architectural plans for the building were drawn up by Mr. J. E. O. Pridmore, of Chicago, and his chief draftsman, Mr. E. Charles Hemmings. The main body of the building is constructed of the Chicago Hydraulic Company's grey pressed brick and the decorative work was furnished by the Northwestern Terra Cotta Company. Messrs. Charles G. Armstrong & Company, of Chicago, were the consulting engineers for the mechanical and electrical work.

Cast-Iron Piles have been used on two highway and electric railway bridges 30 feet wide



PLAN OF THE BASEMENT.

At its maximum speed, the fan is depended on to discharge from 30,000 to 35,000 cubic feet of air per minute, which is sufficient to change the air in the auditorium once in every five minutes if desired, though once in twelve minutes is calculated to be often enough. The seating capacity being 1,000, this makes a provision of about 30 cubic feet per minute per person. From the fan the air is forced through galvanized flues to the horizontal loops over the auditorium ceiling, from which it is discharged through ornamental perforations in the ceiling, and to the two registers about midway up at either side of the proscenium. These registers are set at an angle with the stage wall so as to discharge the air away from the stage. The form of the ceiling loops is indicated by dotted lines on the plan of the theatre. It will be seen that there is a circular loop within a larger elliptical loop. These are fed from two risers, one at each end, by short, flat, flaring connections.

All bends in connections and distributing ducts are made with a large radius to permit an easy flow of air, and the branch pipes to the various flues have dampers to equalize the distribution of air in all parts of the auditor-

over the Weweantit River between Marion and Wareham, Mass. The teredo destroys oak piling within five years at this place, so grey-iron piles of a cruciform section were adopted. They are 10 inches in diameter, weigh 60 pounds per foot, and have 1-inch webs. One bridge is 82½ feet long, with four bents of four piles each, and the other is 108 feet long, with five bents. Each pile has a lower section 30 to 34 feet long and a 6-foot upper section; the two are connected by a cast-iron sleeve in which the parts are held firmly by lead poured in while molten. On top of the pile there is a hollow cap adjustable vertically about 2 inches and held by lead. Mr. C. H. Howes, resident engineer of the Massachusetts Highway Commission, who had charge of the work, states that great care was used in driving the piles to keep them perpendicular and in place, as well as to bring them to a fairly true grade. Blocks of 3-inch white oak about 15 inches square were used as a cushion between the pile top and the hammer, the number of blocks ranging between two and sixteen. Better results were obtained with a 2,200-pound hammer falling 12 to 15 feet than with a longer fall. The bridge was built by the Berlin Construction Company.

The New Works of the B. F. Sturtevant Company.

The new works of the B. F. Sturtevant Company, now nearing completion, at Hyde Park, Mass., present an excellent opportunity to study the factors that control in the location and design of the modern manufacturing plant. The present plant at Jamaica Plain, Mass., is limited in its opportunity for growth, and the fire which occurred last year forced an immediate solution of the question of removal. Aside from the general character of the lot itself, the principal factors considered in reaching a decision were proximity to raw materials, and to an abundance of skilled labor, adequate shipping facilities, ample water supply, and space for ready disposal of waste material. The best combination of advantages was presented by a lot of nearly 20 acres of land in the town of Hyde Park, Mass., 6 miles from the old plant. The lot selected has a frontage of about 1,300 feet upon the freight yard of the New York, New Haven & Hartford Railroad, at Readville Station, the distributing point for all freight passing over either the Midland or Providence divisions of that road. One side of the lot is bounded by Mother Brook and the adjacent shore is at a level of nearly 10 feet below that of the yard and buildings, thus providing sufficient space for dumping waste material for years to come.

As regards the buildings the individual and aggregate areas were determined on the basis of recommendations made by the heads of departments, and the plans started with the idea of providing a total floor space slightly more than double that of the present plant. The lay of the land and its available area being somewhat against a group of one-story buildings, and a simple calculation showing that the actual cost of the power expended in a single year for lifting the entire produce of the works through a distance of 20 feet figured only a little over one dollar, determined the company upon the building of multi-storied buildings. It is believed that the fixed charges on elevating machinery will be more than offset by a reduction in the horizontal distances otherwise necessary to be traversed.

One arrangement of the buildings studied provided for a group of buildings parallel to the railroad tracks with accommodation for switch tracks between the buildings, and for their entrance at the ends of the building with an opportunity for growth by extension in length, and this plan was adopted. The accompanying small plan shows by the shaded portions the opportunity for increase of size in each of the buildings.

The type of building finally selected consists of steel interior columns and main steel girders, with heavy brick walls, wood timbered floor and plank roofs. In the case of the one-story foundry, the roof is supported by steel trusses; in the other buildings open timbering with wooden columns in the upper floor is employed. The main floor in the machine shop is of tar concrete with spruce and maple flooring. The upper floors are carried upon wooden beams spanning the spaces between the steel girders, which follow a unit system of 20 feet on centers through the building. All roofs are of 3-inch plank with tar and gravel top.

The question of power was early decided to the extent that the entire plant would be electrically driven from a central power house; that the engines would run condensing; that the exhaust steam derived from engines under test, which is considerable, would be utilized for heating with a supplementary amount of live steam admitted at reduced pressure as might be required. The power house was placed sufficiently far from the ends of the buildings to permit sufficient extension of each, and near enough to the water supply to reduce to a minimum the expense of conveying and condensing other water.

The accompanying plan of the buildings will indicate the consideration given to the transfer of materials throughout the plant. The pattern building provides at one end a two-story portion 80 feet square for carpenters and flask makers on the first floor, and for pattern makers on the second floor. The rest of the building, which is devoted to pattern storage, is provided with intermediate floors making four in all separated from the other portion of the building by double fire walls and automatic fire closing doors. The close proximity of this building to the foundry facilitates rapid intercourse.

The foundry, 170x350 feet, is to be equipped with narrow-gauge railways bedded in concrete making runways between the moulding floors. Two craneways run lengthwise through the building the greater part of its length, and the tracks extend beneath the crosswise traveling crane in the cleaning room at the end of the building. The brass foundry is located in one corner, a wash room in the adjacent corner, a core room between the two; the latter has ample opportunity for growth towards the center of the building, while the foundry itself can be extended to practically double its length. Storage for supplies is provided upon one side adjacent to the railroad switch. From the bins thus provided, the iron and fuel charges will be carried directly to the charging floor.

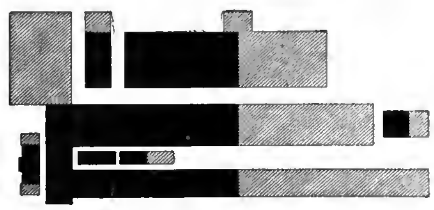
From the foundry the castings will pass to the rear of either the machine shop or the fan shop. The former is of the gallery type, 500 feet long, with wings 40 feet wide, and center runway of the same width for crane of 20 tons capacity. The lighting will be principally by a series of saw-toothed skylights running crosswise of the roof with glass facing due north. The crane will serve the entire floor and transport heavy castings from the machine tools to the erecting floor, where the completed engine or generator may be lifted upon a transfer car passing through the testing building. There it will be picked up by another 20-ton crane, which will drop it upon the testing plate and subsequently carry it forward to the steam railway track, which passes through the end of the building and provides space for the loading of two cars at one time. The upper floor of this building together with portions of the adjoining buildings is devoted to the electrical department and provided with individual small traveling cranes.

The building devoted to the manufacture of fans, heaters, etc., is 80 feet in width, of the same length as the machine shop, is three stories in height, of typical mill construction, provided with all conveniences for handling material and arranged so that shipment can be made from numerous points along one side, while supplies are brought in from the court between it and the machine shop.

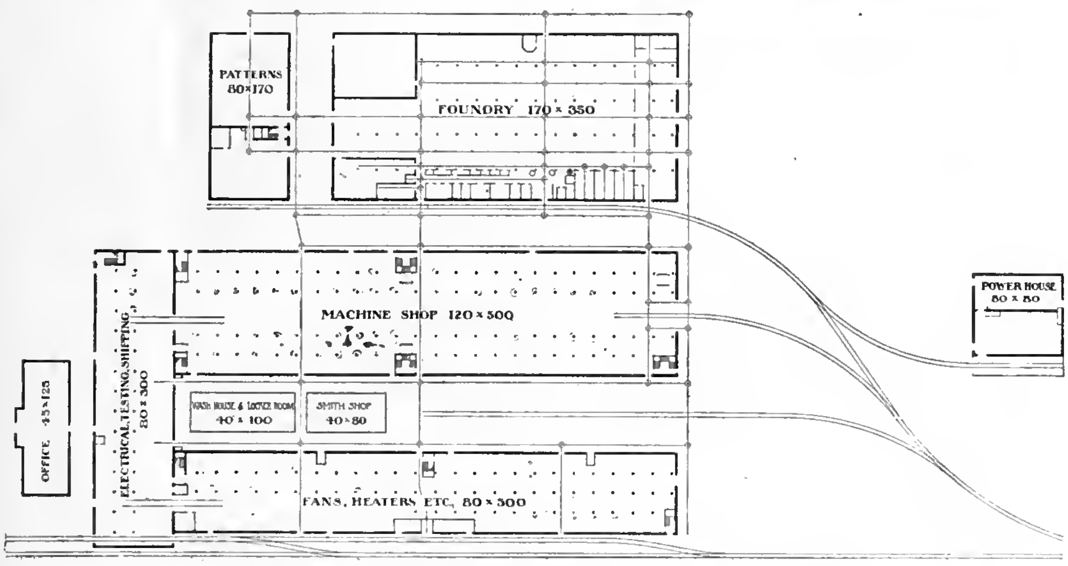
The smith shop, 40x80 feet, serves both buildings with equal facility, while the wash house and locker rooms measuring 40x100 feet, and three stories in height, is located as to reduce to a minimum the distance to be traversed by the individual workmen. The third floor will be used as a lunch room.

The standard first-floor height in the main building is 17 feet, that of the second and third stories is 15 feet. The windows are large and numerous.

The office building will contain the correspondence, designing and drafting offices, the superintendent's quarters, and the cost department, the advertising bureau and a printing office, which will be located in the basement. It will be three stories in height with a finished attic to provide additional drafting room space.



Possible Additions to the Plant.



New Plant of the B. F. Sturtevant Co., Hyde Park, Mass.

The equipment of this plant will be largely Sturtevant in its character. Beginning with the power plant, the mechanical draft apparatus, then engines and generators and the exhaust head will be of Sturtevant make. The building will be heated by the Sturtevant system, the shafting and individual machines driven by motors of the same make, the refuse from the wood-working machinery, the dust from the cleaning room of the foundry, the ventilation of the offices, toilet rooms, and wash house, and the removal of smoke from the smith shop will be accomplished by the Sturtevant exhaust fans, while Sturtevant blowers will be used for brass and iron foundry, forge shop blast and the like, and the firm's vent steam traps will be employed upon the steam dryers.

The Sault Ste. Marie Power Plant of the Consolidated Lake Superior Company, which has been under construction for four years, was started for the first time October 25. The plant cost about $4,000,000 and will develop 60,000 horse-power.

Association of Municipal Engineers of New York City.

On October 3 several engineers connected with various municipal departments of New York City held an informal meeting to discuss the advisability of organizing an association comprising all the engineers in the service of the city. The movement thus begun is said to be well received, and now another forward step is being taken. A circular letter has been issued by a sub-committee on organization, Messrs. M. L. Blum, chairman, A. N. White and M. H. Lewis, setting forth the purposes of the proposed society and giving every engineer connected with the city departments an opportunity to express his desire to join, by filling a printed form attached to the letter.

The aims and objects of the proposed society are stated to be as follows: To cover a scientific field not covered by any existing society. To bring municipal engineers together socially and professionally in order that the problems arising in their several departments may be freely and informally discussed, and that by this means each member may learn the functions of the various departments—what they accomplish and what they endeavor to accomplish, and assist in this accomplishment. To assist in systematizing and standardizing the information in the possession of all departments, establish uniformity in the keeping of engineering records, study the details of office practice, co-operate with the authorities so that duplication of work by the different departments may be avoided, and act in conjunction with other bodies in investigating various problems in municipal engineering. To establish a library of publications pertaining to municipal engineering, statutory laws affecting engineering, statistics as to durability and costs of engineering works, to keep on file plans and specifications of all municipal construction, and reports of other technical societies, and to publish information that may be of value to the engineering profession.

Believing that the service to the city and the interests of the engineers will be mutually conserved by a logical system of grades and promotions, it is proposed that the society make a study of the civil service systems of various countries and lend its efforts to the civil service authorities in establishing a comprehensive and efficient system in the municipality, a system under which ability and efficiency will receive due recognition. There is at present in the city a large body of engineers, about eight hundred in all, engaged on municipal work who have no common meeting ground and consequently are as widely separated as if divided into small parties scattered throughout the country, nevertheless these engineers have many interests in common which suffer through lack of united effort toward a given purpose.

It is believed that the engineers of the departments have missed many advantages because of the lack of a mutual interchange of information and unity of efforts to secure desired improvements. Although a large amount of interesting work is conducted by the engineers of the city, most of the men are acquainted only with the particular work with which they are immediately connected and so miss the educational advantages of a broader knowledge of the works of all departments.

There may be similar organizations to the one above proposed already in existence, but The Engineering Record does not know of any. In some places the necessity for such an association is met, at least in a measure, by the local society of engineers; but in some of the largest cities there may be fields for such movements which could be cultivated to advantage. The objects stated by the organizers of this New York association raise a question or two. Should not the engineers of the various departments of a city be so correlated as to avoid much duplication of work and materially aid one another in the collecting and recording of data? And why should not the engineers of the quasi-public corporations having tracks, pipes, ducts or other structures in the streets contribute their share in the matters of information and records? In some communities these ends are accomplished partly by the personal efforts of the city engineers, but in some municipalities there are large departments employing engineers who do not come under the control of the city engineer.

Diffusion of Light Through Windows.

An instructive report on the relative diffusing powers of various kinds of window glass has recently been issued by the Insurance Engineering Experiment Station, 31 Milk Street, Boston, of which Mr. Edward Atkinson is director. The report, from which the abstract below was prepared, was written by Prof. Charles L. Norton, of the Massachusetts Institute of Technology, who is in charge of the laboratory of the experiment station, and sets forth the results of extended investigations. Some observations by Mr. Atkinson have been added. The results of the tests on a score or more of different glasses may be stated briefly as follows:

We may increase the light in a room thirty feet or more deep to from three to fifteen times its present effect by using "Factory Ribbed" glass instead of plane glass in the upper sash. By using prisms we may, under certain conditions, increase the effective light to fifty times its present strength. The gain in effective light on substituting ribbed glass or prisms for plane glass is much greater when the sky-angle is small, as in the case of windows opening upon light shafts or narrow alleys. The increase in the strength of the light directly opposite a window in which ribbed glass or prisms have been substituted for plane glass is at times such as to light a desk or table fifty feet from the window better than one twenty feet from the window had previously been lighted.

Ground glass is of little value, except as a softening medium for bright sunlight. Its rapidly increasing opaqueness with moisture and dust makes it undesirable as a window glass. The common rough plate has very little action as a diffusing medium, giving no perceptible change in the effective light. "Ripple glass" has great value as a diffusing medium in small rooms with nearly open horizon. Of the ribbed glasses, the fine "Factory Ribbed," with twenty-one ribs to the inch, is distinctly the best, not in all probability because of the fineness, but because of the greater sharpness of the corrugation. The "Ribbed Wire" glass is about twenty per cent. less effective than the ordinary "Factory Ribbed" glass. The addition of a second corrugation upon the back of the plate giving the "Skylight" and "Washboard" glass is of no apparent value. The raised pattern imprinted upon one surface of the glass, as in the case of the "Maze," gives the widest diffusion, especially in bright sunlight. A raised figure, when worked upon the back of the "Ribbed" glass, renders it less offensive to the eye in bright sunlight, but less effective in deep rooms.

The exceeding brightness of all the specimens except the "Maze" and ground glass when in the bright sunlight, is such as to forbid their use where they are constantly in sight, unless they be provided with shades of thin white cloth. This practice of using a thin white shade is to be commended, as it gives a maximum of light when it is needed, in dull weather, when the shade need not be drawn, and yet keeps the eyes protected from a painful glare in bright sunlight. The white cloth shade cuts off about sixty per cent. of the light.

As the result of the test made in a room fifty feet by forty feet, we are able to draw the following conclusions:

First.—The conditions in a room less than fifteen feet deep are such that, except with a sky-angle of less than forty-five degrees, it is not advisable to alter the general course of the light by using a prismatic or ribbed glass. A nearly hemispherical diffusion, such as is given by the "Maze" or "Ripple," is ordinarily preferable.

Second.—When a room is from twenty feet to sixty feet deep, or even more, and has a sky-angle of sixty degrees or less, the ribbed and prismatic glass gives a very great gain in effective light. The gain in brilliancy is such as to make a basement with prism canopies as light as a second story without them, and the first story with ribbed glass should be distinctly brighter than the second story with plane glass. If the building which obscures the light from the sky at a window be increased two stories in height, it will be found possible to restore the light by the use of ribbed glass, and to even improve its earlier condition by a prism canopy. The assumption is here made that the obstructing building is at least thirty feet distant. Rooms with windows opening upon light shafts and narrow alleys with very limited sky, where the available light is now small, may have the light twenty feet back from the window increased ten or twenty times by using prisms; and, by using canopies of prisms, it is sometimes possible to strengthen the light from fifty to one hundred times.

"Ribbed" and "Maze" glass are of very great value in softening the light, especially in the case of such windows as are exposed to the direct sun, aside from their effectiveness in strengthening the light at distant points. With the "Maze" glass, the artist may have, in all weather and in all directions, what is in effect a much-desired "north light." The photographer may have in this way as well diffused a light as he now has with cloth screens or shades, with a much greater intensity. To be efficient in rooms of twenty feet deep or more, ribbed glass should be set with its ribs horizontal, and where the sunlight falls upon it, it should be provided with thin white shades. All inferences drawn from the test are made upon the assumption that the windows are to be reglazed with diffusing glasses only in the upper half, which is the common practice. If the lower sash is to be reglazed as well, a further increase of about twenty-five per cent. may be expected.

Considering both expense and efficiency, the following general suggestions are given:

Use "Maze" or "Ripple" glass in small rooms or offices not more than fifteen or twenty feet deep.

Use "Factory Ribbed" glass in rooms thirty to fifty feet deep, with sky-angles of sixty degrees or more.

Use prisms or "Factory Ribbed" glass, in sheets, in all vertical windows in rooms more than fifty to sixty feet deep, with sky-angle of less than forty-five degrees. With a sky-angle of less than thirty degrees, use prisms in canopies.

It must be borne in mind that one factor, which can be merely hinted at in this report, may be the one which decides the matter of the selection of any one glass, that is, the cost. At present prices we may assume that the "Factory Ribbed" glass costs but little more than ordinary double-thick plane glass. The cost of rolled prismatic glass is not yet established. The cost of the cast prismatic glass is of necessity much greater than of either of the others.

In the first cases in which "Factory Ribbed" glass was used, the ribs were placed horizontally, but the line of bright light thus deflected towards the eyes of the workman may become injurious, and, although the diffusion from horizontal lines is a little better and more effective, the plan of setting is now to place the ribs vertically.

The conclusions which may be deduced from the tests made by Professor Norton, with a window twelve inches square serving as the sole source of light in a large hall with dark ceiling, are:

First.—Windows of the customary height, but of one-third the width commonly adopted, when glazed with ribbed or suitable prismatic glass, will give on a bright day as much effective light as the full width of window glazed with plane glass; on a cloudy day or in a position where the light from the sky is derived from a limited area, even a greater ratio.

Second.—Windows of the type now common in mills, workshops or school rooms, fitted with plane glass, if reglazed in the upper half only with ribbed or prismatic glass, will yield on a bright day more than fifty per cent. excess of effective light, or on dark days a larger ratio. If reglazed down to but not including the lower panes (in which we advise plane glass), the increase in effective light will be much greater.

Third.—Whether or not the increase of effective light will be as great in a room now fully lighted by the customary number of windows of plane glass as in this hall lighted with a single twelve-inch window has not yet been determined, but it has been proved in mill practice that the light is much improved in quality and is rendered much more effective, both near to and far away from the windows.

It may be judicious in all cases to glaze the lower row of panes in factory, workshop and school house windows with plane glass, so that the unpleasant impression of not being able to look out may not be given. It has sometimes been suggested that some portion of each window should be of plane glass for hygienic reasons, upon the ground that "sunlight transmitted through plane glass has a greater hygienic value than that which is refracted through a denser medium." The roughened glass of various types is not a "denser" medium. The glass only diffuses or deflects the rays of light. The hygienic value of this diffusion in its effect upon the eye, when the plates are rightly adjusted, cannot be questioned. It has also been observed that the heat of the sun is diffused, as well as the light, making the warming of the room more uniform.

Wired glass is now cast with ribbed or corrugated surfaces for the diffusion of light. If such glass, set in metallic frames, is substituted for plain glass windows at points where there is danger of fire passing, safety will be well assured with improvement in the lighting. Insurance companies now accept such wired glass windows where they were previously obliged to ask that window spaces should be bricked up. In closing windows against fire, either the "Maze" or the ribbed wire glass may be adopted, assuring safety and at the same time improving the light within. Care should be exercised in setting thick wired glass in metal frames. The lower edge must, of course, bear directly on the frame. The sides and top should be fitted loosely, so that the differential expansion and contraction of glass and frame may not crack the glass.

A Hydrographic Survey is to be made of the principal rivers of Wisconsin to determine the possibilities for water supply and power development.

The Escalator.

A notable installation of moving stairways is now approaching completion in a large department store recently erected in New York City, opposite Herald Square, for Messrs. R. H. Macy & Company. It comprises four stairways serving five floors, each stairway guaranteed to carry 10,000 people per hour. The stairway is known as the Escalator, which is a copyrighted name derived by the inventor, Mr. Charles D. Seeberger, to define the device as a means for securing progression from one plane to another. While a considerable number of Escalators are already in operation in this country, the Macy Escalator plant is the largest yet built by the makers, the Otis Elevator Company.

View of the Escalator and Shunt.

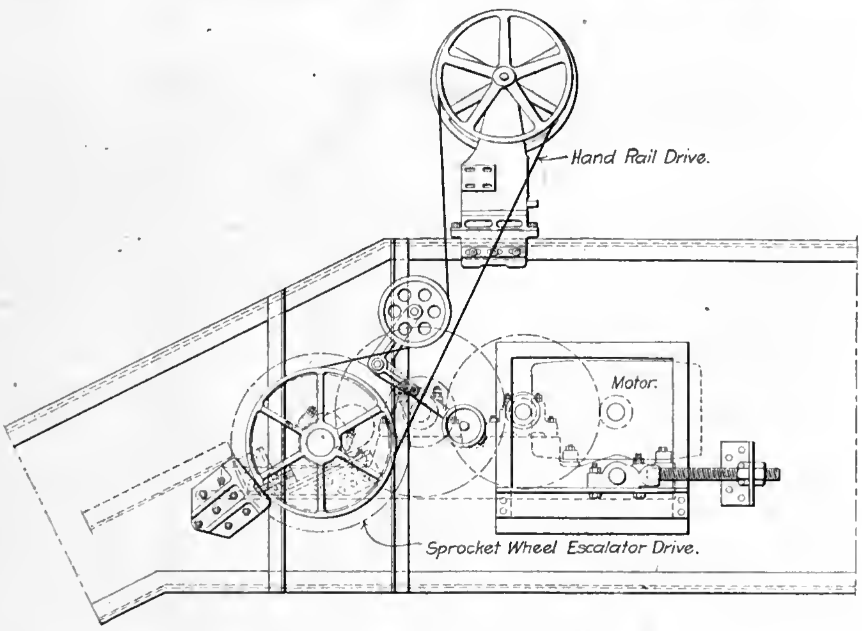
The Escalator consists of an endless series of steps connected together by a heavy sprocket chain which at the upper part of the machine engages with the driving sprocket wheel. Each step is essentially a four-wheel truck, bolted to an axle, which, in turn, is connected to the links of the driving chain. There are two wheels at each end of the truck moving on separate tracks which are so placed that the steps remain horizontal at all points of the ascent. At the landings at the top and bottom of the Escalator, the tracks, and therefore, the trucks, travel in the same plane, so that the steps there become a moving sidewalk making it easy to step on or off. A traveling handrail is provided at each side of the stairway, moving at the same speed as the steps.

Should a person fail for any reason to step off at the upper landing, a device called a shunt removes him from it. This consists of a box-like affair, triangular in plan, with the apex pointing against the direction of the moving platform. In the lower part, set in a vertical position, are two belts running backward from the apex in opposite directions, diagonally across the landing, brushing the person from the side of the platform on which he happens to be. The shunt is generally placed about 10 feet from the top of the Escalator, as indicated in the accompanying reproduction of a photograph of the top of the first stairway.

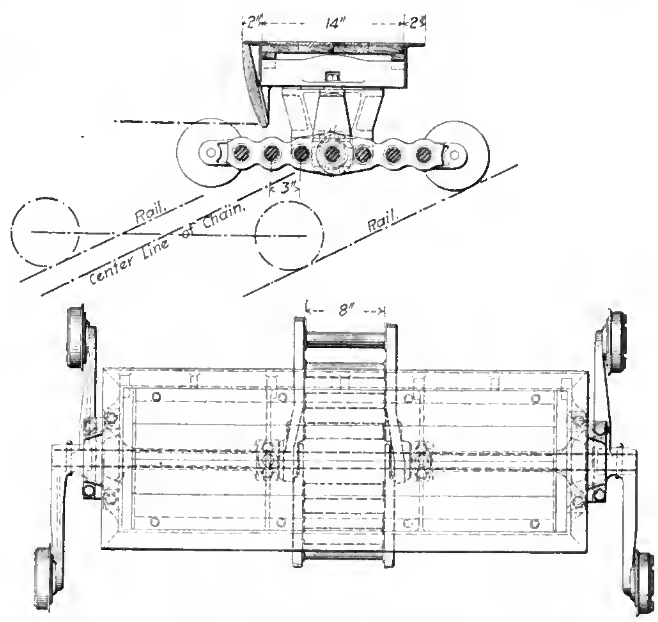
In the accompanying drawings are shown the general construction of the unit of the system, that is, the truck, and the arrangement of the drive, which is obtained by means of an electric motor with speed reduction through spur gearing. The Escalator is supported by a steel frame carried by the structure of the building itself, and rises upward at an angle of about 26 or 27 degrees with the horizontal. One hundred trucks were required, so that it can readily be appreciated that not only must the parts be interchangeable and constructed of durable material, but considerable care is required to obtain practically noiseless operation.

All parts of the running gear are made of crucible cast steel and the axles and link pins of cold-drawn steel. The parts are made to micrometer measurements, bolts being made to fill holes exactly without clearance, so that when erected no adjustment is necessary. The risers of the steps, which are 8 inches in a vertical distance, are formed with a curved surface, as shown, and are finished to the required convexity by automatic machinery designed for the purpose. So closely does the tread of each step remain against the riser of that next above it, during both the inclined travel and the assumption of the horizontal position, that a piece of paper can hardly be forced in the space between. In fact, the aperture is barely visible.

The links of the sprocket chain are made of two 18-inch cast-steel shrouds, with 1½-inch steel pins between them, at 3 inches between centers. The ends of the links are bushed with phosphor bronze, in which graphite is inlaid, thus providing lubrication to the bearing surfaces. In the interest of noiseless operation, the tracks are made up of wood and steel, with a layer of rubber between the tracks and the



Location of the Escalator Drive.



One of the Units, or Steps.

structural iron-work. Raw-hide pinions are used in the gearing and the wheels on which the steps run are deadened with a lead filling. The wheels are provided with graphite lubrication. For driving the Escalator, including the hand-rail, a 25-horse-power motor is installed, running at about 600 revolutions per minute. This speed is reduced by three sets of spur gearing to between 10 and 11 revolutions at the sprocket wheel, which drives the chain at 100 linear feet per minute, a speed that has been found satisfactory. It is stated that this speed will be increased when the public becomes accustomed to it.

The first Escalator in public service was installed in one of the buildings at the Paris Exposition of 1900. Since then Escalators have been placed in the Siegel-Cooper stores in New York and Chicago, in the Simpson Crawford Company's store in New York, Gimbel Brothers' store in Philadelphia and at the Twenty-third Street station of the Sixth Avenue Elevated Railroad in New York. In most of these the worm and wheel type of speed reduction has been employed. One of the most promising future installations will be made for one of the New York rapid transit railroad stations where an Escalator known as Duplex type will be built to carry passengers both up and down, the two flights being in the same plane.

Personal and Obituary Notes.

Mr. P. L. Reed has been appointed civil engineer in the U. S. Navy.

Mr. Edward A. Bond has been re-elected engineer and surveyor of New York State.

Frederick C. Waite, at one time city engineer of Leavenworth, Kan., was found dead in his rooms in that city October 27.

Messrs. Millard F. Tompkins and Henry G. Colvin have been elected directors of the O'Rourke Engineering Construction Company, of New York.

Mr. S. H. Neely, of the supervising architect's office, Treasury Department, Washington, has been detailed to supervise the construction of the United States legation building at Pekin, China.

Major Smith S. Leach, Corps of Engineers, U. S. A., and Lieut. George M. Hoffman, Corps of Engineers, have been appointed members of a board to study the water supply question at Fort Leavenworth, Kan.

Mr. William H. Wiley, of the well-known firm of publishers of scientific books, John Wiley & Sons, New York, and since 1884 treasurer of the American Society of Mechanical Engineers, has been elected to Congress from the Eighth District of New Jersey.

A dinner was held in New York November 10 by some 150 prominent architects to celebrate the twenty-first anniversary of the establishment of the School of Architecture of Columbia University and to honor its founder, Prof. William R. Ware.

Charles H. Miller, for many years consulting landscape engineer of the Fairmount Park, Philadelphia, died November 2 at his home in Mount Air, Pa., aged 73 years. He was made chief of the Bureau of Horticulture at the Centennial Exhibition in 1876.

Mr. Wm. Paul Gerhard gave a lecture before the students of the Massachusetts Institute of Technology, on November 1, on "The Sanitary Engineering Work of Large Modern Buildings," the lecture being illustrated by drawings and lantern slides.

Messrs. Kern Dodge and Charles Day, of the firm of Dodge & Day, Philadelphia, modernizing engineers, have returned from an extensive trip through the middle West, where they visited many of the principal machine shops and foundries gathering data on shop efficiency and factory methods.

Mr. A. S. Cheever, M. Am. Soc. C. E., has been appointed superintendent of the Fitchburg Division of the Boston & Maine Railroad, succeeding Mr. F. O. Melcher, M. Am. Soc. C. E., who resigned to become superintendent of the Illinois Division of the Chicago, Rock Island & Pacific Railway.

Mr. C. W. Bradshaw, superintendent of the Ohio & Northern division of the Louisville & Nashville Railroad, has been appointed superintendent of the Atlanta, Knoxville & Northern Railroad, and will be succeeded at Russellville, Ky., by Mr. Samuel Calloway, assistant superintendent at Birmingham, Ala.

President Palmer C. Ricketts, of the Rensselaer Polytechnic Institute, Prof. William H. Burr, of Columbia University, and Mr. Henry W. Hodge, of Boller & Hodge, New York, have been appointed a special commission to pass upon the relative merits of the revised and original plans of the Department of Bridges of New York for the Blackwell's Island bridge.

Mr. R. E. Newton, Assoc. M. Am. Soc. C. E., is now interested in the Newton Engineering Co., of Milwaukee, Wis., recently incorporated, which is equipping a shop for structural steel-work. He was at one time in the employ of the Keystone Bridge Works, and of the Wisconsin Bridge & Iron Co., and for several years was structural engineer of the Boston & Montana Mining Co.

William Forsyth, a former surveyor of the District of Columbia, died in Washington, November 4. He was born near Dublin, Ireland, in 1820, received his early engineering training in Europe and came to American in 1850, settling the following year in Washington. He had much to do with the planning and construction of street and sewer work in Washington, and did not retire from his official position until 1897.

Mr. Arthur E. Horton, who has been in the engineering department of the Metropolitan Park Commission of the Commonwealth of Massachusetts since that commission was first organized, has opened offices in the Tremont Building, Boston, as manager of the American Bureau of Information, National Industries, to engage in consulting work in preliminary and topographical surveys, adjusting boundaries, special map work, etc., for civil, mechanical and mining engineers and landscape architects.

Mr. L. E. Chapin, M. Am. Soc. C. E., and Mr. Morris Knowles, Assoc. M. Am. Soc. C. E., have formed a co-partnership for the practice of general and consulting engineering, with offices in the Frick Building, Pittsburg, and in the Central Savings Bank Building, Canton, O. For eight years Mr. Chapin was city engineer of Canton, and for the past eleven years has been in private practice. During the last five years Mr. Knowles has been engaged in water-supply investigation for Pittsburg, Philadelphia and New York City, and is still connected with the Pittsburg filtration work.

The following candidates for different grades of membership in the American Society of Civil Engineers were announced elected November 5: Member: U. B. Hough, mechanical engineer, Bunker Hill & Sullivan Mining & Concentrating Co., Kellogg, Idaho. Associate members: H. J. Chambers, with Milliken Bros., New York City; F. R. Davis, resident engineer, Buffalo, Rochester & Pittsburg Ry., Juneau, Pa.; L. H. Davis, chief assistant engineer, Lake Superior Power Co., Sault Ste. Marie, Ont.; A. B. Diehr, U. S. Dredge Epsilon, Memphis, Tenn.; W. H. Ham, engineer, New York Expanded Metal Co., New York; W. D. Hubbard, superintendent of water-works and sewers, Concord, Mass.; J. J. Pemoff, assistant engineer, Department of Docks & Ferries, New York; J. J. Walker, engineering department, American Bridge Co., New York. Juniors: G. J. Davis, Jr., Washington, D. C.; G. T. Paraschos, Constantinople, Turkey; E. M. Rhett, U. S. Engineer School of Application, Washington; F. M. Weaver, Philadelphia; Eduardo Ortiz, Mexico City, Mexico.

The Efficiency of Meters in keeping down the water consumption is commented on as follows in the annual report of the Board of Water Commissioners of Detroit: Sixty premises on which meters still remained, but where the owners were paying by estimated rates, were placed back on the meter roll on account of their large consumption, and it is astonishing how quickly the consumption on such places drops back to the normal quantity when they are obliged to pay by meter instead of estimated rates. They seem to think it no crime to waste public property, but when they have to meet the cost individually, it is immediately reduced to the minimum amount.

The Apportionment of Water Power at Ogdensburg, N. Y., became such a complicated matter in 1872 that the Supreme Court was called upon to settle the conflicting claims. The Oswegatchie River is dammed there by a timber structure, first built in 1796, and the water is delivered to mills through an open canal, except in the case of the municipal water-works. The power is partitioned into 26 first-class privileges and 75 of the second-class, and 62 of these, including all of the first-class, are in use. The method of apportionment, according to the U. S. Geological Survey, involves a system of weirs with movable crests, one at the entrance to each penstock. The head is never allowed to go below 8 feet. During low-water, excessive draft is prevented by raising the weirs. The crests of the weirs for second-class privileges are kept 1½ feet above those for first-class. A standard form of weir with a crest 4 feet long is used for all privileges.

The Action of Distilled Water upon lead was the subject of a report by Dr. Frank Clowes, the Chief Chemist and Superintending Gas Examiner to the London County Council, who has been investigating the subject and communicated the results to the members of the British Association at their recent meeting in Belfast, as stated in a recent issue of the "Journal of Gas Lighting." As the outcome of his experiments, he came to the conclusion that dissolved oxygen is the cause of the action of distilled water upon lead; the subsequent action of carbonic acid leading to the production of hydroxycarbonate. As it has been suggested that the action of water upon lead is indirectly due to the presence of bacteria, Dr. Clowes, in the course of his experiments, frequently exposed water sterilized by long boiling to lead which had been fused in a flask sterilized by steam in the presence of air which had passed through cotton wool. The oxidizing action occurred freely in all such experiments, presumably in the absence of bacteria and their products. The action of distilled water, or of soft waters generally, upon lead may be considerably reduced by dissolving various substances in the water. Sulphuric acid, or a sulphate, was found to be most efficient for this purpose; carbonic acid and carbonates proved less so; and lime water still less—in fact, it even promoted the action when it was used in larger proportion.

CONTRACTING NEWS

OF SPECIAL INTEREST TO

CONTRACTORS, BUILDERS, ENGINEERS AND MANUFACTURERS

OF ENGINEERING AND BUILDING SUPPLIES.

For Proposals see pages xv, xviii and xxvii.

WATER.

Peabody, Mass.—Engrs. Snow & Barbour, of Boston, write that C. E. Trumbull & Co., of Boston, have been awarded the contract for constructing 3,000,000 gal. masonry distributing reservoir at the Peabody water works. Price, $36,285.

Salem, Mass.—In regard to the proposition to establish a filtration plant for the Wenham Lake and Longham portion of the city water supply, City Clk. J. Clifford Entwish writes that nothing definite has yet been decided, the matter being in the hands of the Salem Water Bd. of which Frank F. Newell is Chmn.

Walnutport, Pa.—The Blue Ridge Water Supply Co. has been incorporated with a capital of $5,000.

Altoona, Pa.—The Water Comrs. have recommended the purchase of a site in Oakton for the proposed new reservoir for the city, which is to have an elevation of 1,460 ft. above the sea.

Tonawanda, N. Y.—The Municipal Bd. has awarded to the Holly Mfg. Co., of Lockport, the contract for an 8,000,000 gal. pumping engine, for $26,500.

New Castle, Pa.—State Chemist Aschman, of Pittsburg, in a recent report declares the water supply of this city to be impure and not desirable for drinking purposes. A Com. of 6 physicians (of which Dr. W. E. Zerner, Pres. of Lawrence Co. Med. Society, is a member) has been appointed to report upon various plans suggested to secure a pure water supply.

McKees Rocks, Pa.—Press reports state that the Pittsburg & Lake Erie R. R. will shortly let contracts for two water plants to be erected at McKees Rocks at a cost of $25,000 each. There will be two reservoirs with a capacity of 500,000 gallons each. Two pumps will supply the tanks, each having a capacity of 1,000 gallons a minute.

Northampton, Pa.—The Northampton Water Co. has been incorporated with a capital of $1,000. Incorporators: Alvin F. Newhart, Wm. F. Benninger and Benj. W. Roth, of Walnutport, and others.

Vineland, N. J.—The United Water & Light Co., principal office 613 Landis Ave., Vineland, has been incorporated to construct and operate water works, etc. Capital, $200,000. Incorporators: John B. Reynolds, Arthur A. Holbrook and Harry E. Sweeney.

Wilmington, Del.—The Texas Rice Irrigation Co. has been incorporated in Wilmington by Albert Barnes, J. G. Gray and S. S. Adams, of Wilmington. Capital, $500,000.

Meadville, Pa.—City Engr. W. A. Doane writes contracts have been let for drilling further test wells at 72 cts. per ft.

Baltimore, Md.—The ordinance authorizing the issue of city stock to the amount of $1,000,000 to improve the water supply was indorsed by the voters at the election held Nov. 4. The Water Bd. has decided, according to local press reports, to expend next year a portion of this loan as follows: For an additional storage reservoir, $350,000; for improving the upper service in district east of Jones Falls, $70,000, and for Southwestern Annex, $225,000.

Hammonton, N. J.—This town voted at the special election to issue $15,000 additional bonds to complete the water works.

Hillsville, Pa.—According to local press reports it is proposed to construct water works for this place. Geo. W. Johnson, of New Castle, and Delos Ferrell, of Hillsville, are said to be interested.

Oneida, N. Y.—It is stated that bids are wanted Nov. 11 for a 4-in. water main extension on North and Phillip Sts. J. F. Connor, City Clk.

Lancaster, Pa.—The Water Com. has directed the Water Supt. to lay mains on portions of Washington St. and College Ave.

At the recent election it was voted to borrow $145,000 to improve the water supply.

Ft. McRee, Fla.—The following bids were opened Oct. 28 by Capt. W. E. Cole, Q. M., at Ft. Barrancas, Fla., for water and sewer systems complete at Ft. McRee: T. W. Nicol & Co., Mobile, Ala., $14,998; Frank Sutter, Pensacola, Fla., $14,055; C. H. Turner, Pensacola, Fla., $15,775; Geo. H. Crafts, Atlanta, Ga., $14,945; Henry Monk, Pensacola, Fla., $12,250. Other bids received at the same time were as follows: H. T. Sinnott, Nashville, $4,492 for tank and tower; J. R. Keller, Pensacola, $7,836 for tank and tower and $3,800 for pump and boiler.

Richmond, Va.—The Com. on Finance & Water has appointed a sub-committee, of which Mr. Gorden is Chmn., to investigate the different plans suggested for raising necessary money for the construction of a settling and coagulating basin to cost $350,000, also a plan for raising money with which to construct a stand pipe for Lee Dist.

Portsmouth, Va.—The Portsmouth, Berkley & Suffolk Water Co. is asking, through its Gen. Mgr., Geo. H. Hornung, for bids for a 5,000,000 gal. pumping engine, with boilers, for the new pumping plant to be shortly erected at Lake Kilby, the designs of which are now under preparation.

Bristol, Va.—Bids are wanted Nov. 22 for $25,000 water bonds. E. E. Jones, Chmn. of Finance Com.

Gillett, Wis.—Local press reports state that it is proposed to construct water works.

Detroit, Minn.—Press reports state that estimates of cost are being prepared for a system of water works.

Odell, Ill.—An ordinance is said to have been passed that the users of city water must install meters before Jan.

Albia, Ia.—The citizens are reported to have voted a franchise for a water system.

Coulterville, Ill.—According to press reports the Illinois Central R. R. Co. will expend $38,000 in a water system at Coulterville on the St. Louis division. A reservoir covering 20 acres of ground and holding 60,000,000 gal. is now in course of construction, and a pumping plant with a capacity of 31,000 gal. per hour will bring water from the reservoir to a 100,000 gal. tank. W. J. Hanrahan, Ch. Engr. of R. R. Co., Chicago, Ill.

Goodhue, Minn.—The Village Council is considering plans for a new water works system.

Des Moines, Ia.—Local press reports state that the Water Co. will lay a new 24-in. feed main through the factory district between 6th Ave. and 11th St. and south of the railroad tracks.

Westbrook, Minn.—Engr. in Charge M. B. Haynes, of Mankato, Minn., writes that the contract for furnishing all material and completing a water works plant in Westbrook has been awarded to W. D. Lovell, Des Moines, for $6,934. The work includes approximately 1,806 ft. 6-in. mains, 535 ft. 8-in. mains, 7 hydrants, 4 valves and pumping station and an 80-ft. tower of steel with wooden tank. Other bids received Oct. 30 were from Fairbanks, Morse & Co., St. Paul, at $8,994, and from E. T. Webster, Dubuque, Ia., for $8,421.

Columbus, O.—C. E. Perkins, Ch. Engr. of Pub. Wks., writes that the contract for constructing a 2-span steel truss aqueduct, timber trunk, having a total length of 106 ft., to be built 1 mile south of St. Mary's on the Miami and Erie Canal, crossing St. Mary's River, has been awarded to the King Bridge Co., Cleveland, O., for $4,760.

Duluth, Minn.—Bids are wanted Nov. 24 for the purchase of $140,000 bonds issued by this city for the purchase of the West Duluth water plant. H. W. Cheadle, City Clk.

Youngstown, O.—Last week the item in reference to the report of Consulting Engrs. O. H. Jewell and Walter Wagner on the proposed filtration plant for this city, through error appeared under Xenia, O., instead of Youngstown, O.

West Milton, O.—Bids will be received Dec. 1 by John Coate, Village Clk., for constructing water works.

St. Cloud, Minn.—The Water Works Co. is said to have made a proposition to the city to sell the plant or will install a filtering plant if the city will make certain concessions.

East Grand Forks, Minn.—There is talk of laying further water mains for fire protection.

Dexter, Minn.—Bonds are reported to have been voted for a system of water works.

Jewell Junction, Ia.—Bonds for $7,000 are stated to have been voted for the construction of a system of water works.

Wheeling, W. Va.—The Water Bd. is considering the construction of an auxiliary main leading from the water works to the reservoir. Probable cost is said to be $75,000.

East Dundee, Ill.—Bids are wanted Dec. 1 for the construction of a stand pipe, engine and pump, as advertised in The Engineering Record.

Bloomington, Ill.—The sum of $5,000 is reported to have been appropriated for experimental purposes for the proposed improvement of the water supply. Elmer Folsom, City Engr.; J. F. Hulva, Chmn.

Wooster, O.—Consulting Engr. L. E. Chapin, of Canton, is quoted in local papers as having stated that it will cost from $100,000 to $125,000 to secure a good and adequate water supply for this city.

Newton, Ia.—Local press reports state that this place is making an effort to secure a waterworks system.

Marshfield, Wis.—The Common Council has asked for an appraisement of the water works and electric light plant, according to the term of the franchise.

Clinton, Ia.—The citizens of this place are said to be in favor of the construction of water works.

Lawrenceburg, Ky.—The proposition to issue $20,000 bonds for water works and an electric light plant, carried at the recent election.

Tuscaloosa, Ala.—The Tuscaloosa Water Works Co. is said to be preparing to extend the water mains from the Central College through West End, Deer Park and Southside.

Gunter, Tex.—The Gunter Water Works Co. has been incorporated with a capital of $3,000. Incorporators: J. Gunter, John Hardie and others.

Williston, N. D.—The Council is stated to have granted a franchise to ex-Mayor Johnson for the construction of water works and an electric light plant.

Snyder, Colo.—Local press reports state that Surveyor Baker and D. A. Camfield, of the South Platte Reservoir Co., are locating a site for a proposed storage reservoir to be constructed in the vicinity of Snyder, at a probable cost of $100,000.

Boise, Idaho.—Preliminary plans for the reservoir, with a capacity of 10,000 acre ft., to be built by the New York Canal Extension Co., have been filed with the state engineer. Application is made for 670 acres of state land, under the provision of the act of the last legislature, granting state land for reservoir purposes.

San Diego, Cal.—In a recent report to the Common Council City Engr. G. A. D'Hemecourt estimates the cost of building 2 dams in the city park at $14,060 for the lower dam and $13,730 for the upper dam; the estimated cost of constructing a conduit in B St. is placed at $50,440 for a structure of expanded metal concrete having an area of 16½ sq. ft. at the inlet and an area of 33.6 sq. ft. at the outlet.

Walla Walla, Wash.—The City Officials are investigating the gravity water system of Seattle with a view to installing a similar system at Walla Walla.

Seattle, Wash.—The City Engr. has estimated the cost of 22d Ave. water main at $20,928, and Galer St. at $32,500.

Lincoln, Neb.—According to press reports Wm. Frank and others propose the construction of an irrigation system in Scott's Bluff County, to cost $500,000. The ditch will be 150 miles long.

Carlsbad, N. Mex.—Local papers state that the Pecos Improvement Co., F. G. Tracy, Pres. and Gen. Mgr., proposes to construct a concrete flume in place of the wooden one that spans the Pecos River at Carlsbad, and conducts the water of the main irrigation canal; the flume will be 600 ft. long, with 4 steel and concrete piers. Estimated cost, $40,000.

Steamboat Springs, Colo.—Chas. Brown, of Parachute, Colo., and associates are said to have asked the Town Bd. for a franchise to construct water works.

Pueblo, Colo.—The Trus. of the North Side water works have ordered estimates and specifications prepared for a stand pipe, having a capacity of 1,000,000 gal., to be placed near Fairmount Park.

San Luis Potosi, Mex.—Local press reports state that this city is to have a complete system of water works, and a dam holding 400,000 cu. meters of water will be constructed at a cost of $68,000.

Hamilton, Ont.—Mgr. Barrow is said to be in favor of the construction of a storage reservoir for the city's water supply.

SEWERAGE AND SEWAGE DISPOSAL.

Van Buren, Me.—Local press reports state that a sewerage system is about to be put in.

Athol, Mass.—At a town meeting held Oct. 31 it was voted to borrow $20,000 for the construction of an extension to the sewer system, also construct sewers in portions of Main, Leonard and other streets and appropriating $8,000 for same.

Boston, Mass.—Bids will be received Nov. 12 by Jas. Donovan, Supt. of Streets, for sewerage works in portions of Tileston Ave.

York, Pa.—An ordinance providing for a loan of $400,000 for the construction of a sewerage system and disposal plant has passed first reading in the Common Council.

McKeesport, Pa.—Mayor Black has vetoed the ordinance providing for the construction of a $75,000 sewer in the 8th Ward.

Fulton, N. Y.—The State Supt. of Pub. Wks. has granted permission to the Bd. of Pub. Wks. of this city to lay 3 drain sewers running from E. 1st St. and discharging into Oswego Canal.

Wilkesbarre, Pa.—The Councils are considering the proposition to secure a loan of $380,000 for necessary improvements. According to a statement submitted by the City Engr. the required expenditure includes the following: Street Dept., $156,313, it being proposed to replace all cobblestones in the city streets with vitrified brick pavement; for retaining wall on N. Main St., $3,500; for sewers, $126,282; for engine house, $36,000; police station, $30,000 and public baths and crematory, $27,000.

Doylestown, Pa.—Boro. Clk. Jas. Flack writes that John C. Swartley, of Doylestown, is the Engr. in charge of proposed improvements to the sewerage system.

Buffalo, N. Y.—Ass't Engr. Hoffman, of the Dept. of Pub. Wks., writes that the following bids were opened Oct. 31 for the construction of 3,844 ft. of 48-in. to 27-in. brick sewer in Mumford St., with 13 manholes; trench to average 13 ft. in depth and be excavated in loam and gravel: John Mumm, 176 Best St., $14,900; McKeown & Johnson, $15,555; Miller, Franklin & Ritzman, $15,600; Jas. McElroy, $16,847; Dark & Co., $16,953; Beaser Bros., $17,112.

Allentown, Pa.—An ordinance before the Common Council provides for issue of $500,000 bonds for the purpose of installing a house sewerage system and disposal plant.

South Bethlehem, Pa.—Boro. Secy. Thos. Ganey writes that work will be started next spring on the sewerage system which it is proposed to construct at a cost of $100,000. R. K. Neumyer, Engr. in Charge.

Philadelphia, Pa.—The Councils Com. on Surveys has approved the schedule of appropriations needed by the Bureau of Surveys next year; the principal items are: $500,000 for Passyunk Ave. bridge over the Schuylkill; $216,616 for widening Delaware Ave., north of Vine St.; $100,000 for Cohocksink relief sewer; $250,000 for branch sewers; $500,000 for main sewers, and $500,000 for new bridges.

Newburgh, N. Y.—The Common Council has passed a resolution providing for the construction of Haines Crossroad sewer and two other sewers at a cost of $4,850.

Bradley Beach, N. J.—At the recent election it was voted to install a system of sewerage, and issue bonds for same to the amount of $23,800.

Anglesea, N. J.—Bids will be received Nov. 18 by Augustus Hilton, Mayor, for furnishing material for laying about 5½ miles of 8, 10 and 12-in. sewer pipe and constructing manholes and appurtenances. Wm. H. Boardman, Engr.

Brooklyn, N. Y.—Bids will be received by J. Edw. Swanstrom, Boro. Pres., Nov. 19, for furnishing material for alteration of sewers necessitated by Atlantic Ave. improvement subway in Franklin Ave. and other streets. Engineer's estimate is as follows: 2,035 lin. ft. 54-in. brick sewer, 17 manholes, 18,000 ft., B. M., foundation planking, 285,000 ft., B. M., sheeting and bracing, etc.

Oneida, N. Y.—City Engr. Vedder has been instructed to prepare plans and specifications for a sewer in Stone St.

Lancaster, Pa.—At the recent election it was voted to borrow $250,000 to extend and improve the sewer system.

Ft. McRee, Fla.—See "Water."

Ionia, Mich.—Bids will be received Nov. 11 by Marvin E. Kenyon, Co. Drain Comr., for cleaning and constructing a certain drain known and designated as Carbaugh and East Libhart Creek drain, located in Sebiwa, Orange and Portland Townships.

Mason City, Ia.—Bids will be received Nov. 18 by the Bd. of Trus. of the Iowa Odd Fellows and Orphans Home for constructing an 8 and 10-in. tile sewer about 4,425 ft. long. J. W. Marshall, Secy. of Bd., Storm Lake.

Atlantic, Ia.—Local press reports state that plans have been received from the Iowa Engineering Co., of Clinton, for the new sewerage system, which provide for 13 miles of 20-in. to 8-in. pipe sewers, 19 8-in. flush tanks, 12 5-in. flush tanks, 139 manholes and 12 drop manholes. The estimated cost is $42,516, of which $5,000 is for a sewage disposal tank.

St. Paul, Minn.—City Engr. Rundlett is said to be in favor of an expenditure next year of $120,000 for new main sewers.

Dixon, Ill.—According to press reports bids are wanted Dec. 7 for the construction of sewers in several streets. F. A. Truman, Pres.

Youngstown, O.—Local press reports state that new bids will probably be asked by the City Comrs. for the construction of Ingils St. sewer. C. E. Cross, City Clk.

Toledo, O.—Bids are wanted Nov. 17 for the construction of 8, 10 and 12-in. circular pipe sewers in 11th St. and certain alleys. Chas. H. Nauts, City Clk.

Bushnell, Ill.—Citizens are said to be agitating the matter of issuing bonds for a sewerage system.

Duluth, Minn.—The City Engr. has been instructed to make estimates for the construction of a trunk sewer from Grand Ave. to the Bay, following the line of Polk St. Ravine.

Delray, Mich.—The Council has decided to put in 2 sewers. Plans for sewers are said to be in the hands of ex-City Engr. R. H. McCormick, of Detroit.

Rock Island, Ill.—The City Council is reported to have voted for sewer extensions to cost $100,000.

Clinton, Ia.—The City Council has passed over the Mayor's veto a resolution instructing the City Engr. to prepare plans, specifications and estimates for a complete sewerage system for this city.

Paulding, O.—Bids will be received Nov. 25 by the Village Council for furnishing material and constructing a 12-in. sewer, including inlets and manholes, in portions of Cherry St. E. A. Ream, Village Clk.

Norwood, O.—Engr. J. A. Stewart, of Norwood, is reported to have drafted a plan for a sewerage system to start at Evanston, carrying off the sewage of the suburbs of Cincinnati in that vicinity through Norwood and drain, in addition, Hyde Park, Oakley, Pleasant Ridge, Kennedy Heights, Silverton and Madisonville. Probable cost about $200,000.

Peoria, Ill.—Local press reports state that ordinances are about to be introduced in the City Council for the following sewers: for Dist. No. 1, estimated cost $33,000; for districts in North Peoria, estimated cost $87,000, and for Persimmon St. sewer system, estimated cost $19,000.

Bisbee, Ariz.—Press reports state that a company of Tucson capitalists has asked for a franchise to construct a sewer system in Bisbee.

BRIDGES.

Boston, Mass.—The contract for the steel superstructure for sections A and B of the new Broadway bridge has been awarded to the Boston Bridge Works for $112,874.

The contract for building six masonry piers for the Atlantic Ave. bridge to South Boston has been awarded to W. H. Ellis, of this city, and the Mayor has approved the same. His bid was $69,700.

Wilmington, Del.—Press reports state that the Levy Court Comrs. propose to build a new bridge in place of Morrison's bridge over the Christiana.

Pittsburg, Pa.—It is reported that the Pennsylvania R. R. contemplates raising the 30th St. bridge, crossing Allegheny River at Herrs Island, the island end to be raised 20 ft., while the city end remains as at present. W. H. Brown, Ch. Engr., Philadelphia.

New York, N. Y.—Mayor Low has approved the ordinances appropriating $2,920,000 for work on Bridge No. 3, and $1,627,000 for work on the Blackwell's Island Bridge.

Reading, Pa.—The Co. Comrs. are reported to be considering the construction of another bridge across the Schuylkill River at Reading.

Oneida, N. Y.—It is stated that bids are wanted Nov. 11 for constructing a Portland cement concrete culvert over Higinbotham Brook, at Main St. J. F. Connor, City Clk.

McKeesport, Pa.—Mayor R. J. Black is stated to have signed the ordinance providing for the construction of a steel bridge at Versailles Ave.

Philadelphia, Pa.—See "Sewerage and Sewage Disposal."

Petersburg, Va.—Local press reports state that the Va. Passenger & Power Co. proposes either to make improvements to the Free bridge over James River for the electric railway from Petersburg to Richmond, or to build a new bridge.

Chicago, Ill.—Bids are wanted by the Drainage Bd., Sanitary Dist. of Chicago, until Nov. 19 for the purchase of $1,500,000 worth of bonds for the construction of bascule bridges and the widening of the river.

Wapakoneta, O.—Bids are wanted Nov. 28 for constructing a steel leg bridge across Auglaize River 2 miles north of Buckland, said bridge to consist of 1 span 156 ft. in length with 14 ft. roadway; also for constructing a steel leg bridge across Auglaize River 4 miles northeast of Wapakoneta, consisting of 1 span 124 ft. long, with 14 ft. roadway. W. H. Meyer, Co. Aud.

Traverse City, Mich.—At a recent meeting of the Council Engr. Blomshield, of W. Bay City, presented an estimate on a double arch concrete bridge with abutments to cost $16,500. Estimated cost of steel bridge $21,600.

Youngstown, O.—Local press reports state that the city and county propose to build jointly a viaduct about ⅓ of a mile in length to extend from Manning St. to Midland Ave. in the West End.

Delaware, O.—Local press reports state that the Columbus, Sandusky & Hocking R. R. will probably build a steel bridge over its crossing at North Sandusky St. F. R. Barrett, Engr. Maintenance of Way, Detroit, Mich.

Grand Rapids, Mich.—The contract for constructing piers and abutments for Wealthy Ave. bridge is stated to have been awarded to Jos. Higgins, of Grand Rapids, for $23,175.

Joliet, Ill.—The Joliet Bridge & Iron Co. is stated to have secured the contract for constructing the Red Mill bridge for $12,542.

Columbus, O.—The following bids were opened Oct. 30 by the Bd. of Pub. Wks., Julian Griggs, Ch. Engr., for the construction of sanitary sewers:

Bidders and Addresses.	Brick sewers. 4,602 ft. 2-ring, 36", 13 ft. cut.	4,509 ft. 1½-ring, 27", 13 ft. cut.	2,157 ft. 1½-ring 24", 14 ft. cut. Kansas City, Mo.—Plans have been prepared for sewers in Sewer Dist. No. 211, which call for 25,000 ft. of pipe and 5,000 ft. of brick sewers, 101 manholes, 62 catch basins and 5 flush tanks. Total cost, $60,000. R. W. Waddell, City Engr.

Bessemer, Ala.—City Engr. Wm. J. Parkes writes that the time for receiving bids for the Second Ave. Dist. storm sewers has been postponed to Nov. 18; the proposed sewers will range in size from 18 to 42-in., and the estimated cost is $7,500.

Oak Cliff, Tex.—The City Council has granted the Citizens Sewerage Co. a 25-year franchise, for the construction of a sewer system. Incorporators: Ben. W. Smith, E. G. Patton and W. L. Addison.

Central Covington, Ky.—This town has voted $30,000 bonds for sewerage.

Marshalltown, Ia.—City Engr. Wm. Bremner writes that preliminary steps have been taken by the City Council for the construction of a viaduct about 1,500 ft. long, with approaches over the railroad track; nothing will be done, however, until the matter is acted upon by the State R. R. Comrs.

Grand Rapids, Minn.—See "Railroads."

Springfield, O.—City Engr. W. H. Sieverling writes it is proposed to build a combined roadway and electric railway bridge; style, truss or through girder; span, 130 ft.; width, 40 ft; material, medium steel.

Waukesha, Wis.—A section of the Barstow St. bridge, about 35 ft. in length, is reported to have collapsed. A new bridge will probably be constructed.

Niles, Mich.—The South Bend & Southern Michigan Ry. Co. expects soon to contract for a steel viaduct and bridge over the Michigan Central Ry. at Niles; length, about 220 ft. The main span, of about 90 ft., to be plate girder or riveted truss, end spans of rolled beams. W. S. Kinnear, Ch. Engr., Michigan Central, at Detroit, Mich.

Steubenville, O.—Secy. Jas. G. Mitchell, of Rochester, Pa., writes that the Steubenville Bridge Co. proposes to construct a bridge across Ohio River at Steubenville. Engr. in Charge, E. K. Morse, Pittsburg, Pa.

Saginaw, Mich.—Bids will be received by County Road Comr. Herman H. Eymer until Nov. 26 for the construction of the town line bridge across Cass River, to cost about $15,000.

Knoxville, Tenn.—Local press reports state that the Louisville & Nashville R. R. Co. (R. Montfort, Ch. Engr., Louisville, Ky.) is willing to enter into conference with the City and the Knoxville Traction Co. (Jas. Link, Ch. Engr., Knoxville) looking to the joint construction of a viaduct over the yards of the road at Clinch Ave.

Memphis, Tenn.—It is stated that plans have been completed for a $10,000 steel bridge to be constructed at Bway., near Elmwood, for the Southern Ry. (D. W. Lum, Engr. of Bridges, Washington, D. C.), the Frisco (C. D. Purdon, Ch. Engr., St. Louis, Mo.), and the Nashville, Chattanooga & St. Louis R. R. (Hunter McDonald, Ch. Engr., Nashville).

Tacoma, Wash.—A Council Com. is reported to be investigating the question of constructing a bridge across Puyallup River at St. Paul Ave. and a roadway across the flats on piles.

Milwaukee, Ore.—Preliminary surveys are stated to have been completed for a bridge for the Southern Pacific Ry. Co. across Willamette River, a short distance south of Milwaukee. R. Koehler, Mgr., Portland.

Chippewa, Ont.—Engr. in Charge Geo. Ross, of Welland, Ont., writes that the contract for building the superstructure of a steel bridge across Welland River at Montrose, 4 miles from Chippewa, has been awarded to the Hamilton Bridge Wks. Co., of Hamilton, Ont., for $8,117; the contract for the substructure was awarded to Jos. Battle, of Thorold, Ont., total, $10,998.

PAVING AND ROADMAKING.

Boston, Mass.—Bids will be received Nov. 17 by Jas. Donovan, Supt. of Streets, for constructing Columbia road between Buttonwood St. and N. Y., N. H. and H. R. R. bridge; also on the same date for constructing Columbia road between I and Q Sts.

Wilkesbarre, Pa.—See "Sewerage and Sewage Disposal."

Washington, D. C.—The schedule of the Engr. Dept. of street improvements to be undertaken next year in accordance with the request of the Commissioners in their estimates to Congress, includes $110,000 for paving in northwest section; $152,000 for grading, regulating and paving in northeast section; 76,800 for paving in southeast section; $66,700 for paving in southwest section and $41,000 for paving in Georgetown section.

Brooklyn, N. Y.—Bids are wanted Nov. 19 for furnishing material and labor required for the construction of cement concrete sidewalks in various streets; the Engineer's estimate places the total number of sq. ft. at 41,406. J. Edw. Swanstrom, Boro. Pres.

Buffalo, N. Y.—Bids are wanted Nov. 14 for repaving Niagara, 17th and S. Division Sts. and Willow Pl. Francis G. Ward, Comr. of Pub. Wks.

A correspondent writes that the following bids were received for paving Hamburgh Turnpike, from Buffalo River to the City Ship Canal, 36 ft. wide, 9,410 sq. yds.: Asphalt—German Rock Asphalt & Cement Co., $33,000; Barber Asphalt Paving Co., $28,042; Warner-Quinlan Asphalt Co., $33,230; Eastern Const. Co., $31,000; H. P. Burgard, $28,000. Brick—H. P. Burgard, $32,000; Barber Asphalt Paving Co., $30,488; F. V. E. Bardol, $32,000. Medina Sandstone—H. P. Burgard, $37,000; F. V. E. Bardol, $35,000; Wm. H. Kinch, $33,000; Barber Asphalt Paving Co., $41,216.

Hoboken, N. J.—Bids are wanted Nov. 26 for improving 6th and Madison Sts. and Willow Ave. by regulating grade, resetting curbs, relaying crosswalks and repaving roadway with present Belgian blocks. Jas. H. Londrigan, Acting City Clk.

Syracuse, N. Y.—The City Council has approved plans and specifications prepared by the City Engr. for paving Grape St. from E. Genesee to E. Kennedy Sts. with sheet asphalt or brick. The Council has adopted an ordinance providing the amount of money, to be raised to pay for the paving of Butternut St. with brick, be fixed at $67,000.

Silver Lake, N. Y.—Bids are wanted at the office of the Richmond County Park Comrs. until Nov. 17 for constructing road in Silver Lake Park, as advertised in The Engineering Record.

Washington, D. C.—Morris Hacker, Supt. of County Roads has reported to the Comrs. that to macadamize Nichols Ave. southward from St. Elizabeth's would cost $18,000.

Belleville, N. J.—The Bd. of Freeholders has received from Engr. Ralph Earle, of Jersey City, a report which places the estimated cost of improving Belleville Turnpike, for a distance of about 3 miles, at $55,025.

Pittsburg, Pa.—Local papers quote Dir. J. Guy McCandless as having stated that he will recommend appropriations for a large amount of paving for next year. Among the streets to be recommended will be Forbes St. and 5th Ave. to be repaved with asphalt.

Norwood Park, Ill.—In the County Court Judge Lovett has confirmed the special assessment rolls for the paving of a large number of the principal streets in Norwood Park at a cost of $75,000.

Springfield, Ill.—The contract for paving Allen St., over 1 mile long and 36 ft. wide, with sandstone curb, is stated to have been awarded to J. F. Bretz & Son, their bid being $1.38 per sq. yd. from 7th to 2d Sts., and $1.44½ per sq. yd. from 2d to Walnut Sts.; curbing, 54 cts. per lin. ft.

Toledo, O.—The lowest bids received for paving Clark St. were from Garrigan Bros. at $8,010 for vitrified block with $200 extra for concrete, and from C. H. Burchinals at $11,320 for asphalt block.

Bids are wanted by City Clk. Chas. H. Nauts until Nov. 17 for improving John and Machen Sts., Linwood Ave. and Dove Lane, by paving with either vitrified block or asphalt block on a foundation of concrete or a foundation of sand or broken stone. Bids are also wanted until Dec. 1 for the improvement of Detroit Ave. with a block pavement on a foundation of concrete, sand or broken stone.

Cincinnati, O.—City Engr. Stanley has been instructed by the Bd. of Pub. Service to prepare plans and specifications for the improvement of Hackberry St. from the end of the present improvement to Holloway, by paving with brick, and to improve Park Ave., from Foraker to Chapel, by paving with asphalt.

Hamilton, O.—A petition is being circulated asking the Bd. of Control to take necessary steps to have South Front St. paved.

Logan, O.—Bonds will be sold and a contract let early in the spring for 18,000 sq. yds. of vitrified brick paving. Engrs., Sieverling & Bauer, of Springfield, O.

Indianapolis, Ind.—The Bd. of Pub. Wks. has adopted a resolution for the paving of a portion of 20th St. with asphalt. Estimated cost, $22,850.

Keokuk, Ia.—The City Council has authorized City Engr. J. Ross Robertson to ask for bids until Nov. 27 for paving 4 streets and 1 alley, requiring about 4,500 sq. yds. of brick paving and 1,860 ft. of stone curbing. Bids to be received by Rice H. Bell, Clk. of Council.

Dallas, Tex.—Local press reports state that the Consolidated Street Ry. Co. will repave Main St. between its rails, at an expenditure of $67,000.

Topeka, Kan.—Property owners have petitioned for a 90-ft. brick pavement on Kansas Ave. from 10th to 13th Sts., with Allen County or Colorado stone curbing.

Pratt City, Ala.—Bids are wanted for paving and curbing certain sidewalks on 5 streets. J. E. Seay, Chmn. St. Com.

Ft. Worth, Tex.—Bids are wanted Nov. 21 for 25,000 sq. yds. of sheet asphalt and vitrified brick paving for Houston St. John B. Hawley, City Engr.

New Orleans, La.—Local press reports state that bids will be received by the City Comptroller for the repair of all asphalt streets in this city, for the care of which the city is responsible. City Engr. Hardee estimates that there are about 130,000 sq. yds. of asphalt pavement which will henceforth have to be maintained by the city.

Latonia, Ky.—This town has voted bonds to the amount of $30,000 for street improvements.

San Jose, Cal.—A project is under consideration for the construction of a county road to connect Santa Clara and San Joaquin Valleys by way of Mount Hamilton. E. P. Newhall, Surveyor of Stanislaus Co. (Modesto, C. H.), is said to be interested.

San Francisco, Cal.—The Street Com. of the Bd. of Supervisors has approved plans to repave Spear St. with asphalt block at an estimated cost of $11,200.

Redondo Beach, Cal.—Venable & Cleghorn are reported to have received contracts amounting to $46,000 for grading, graveling, guttering and curbing in this city.

POWER PLANTS, GAS AND ELECTRICITY.

South Norwalk, Conn.—The citizens are stated to have voted to appropriate $15,000 to enlarge the municipal electric light plant.

Hartford, Conn.—Mayor I. A. Sullivan is reported to be in favor of municipal ownership of the gas plant.

Mahanoy, Pa.—The Boro. Council is stated to have granted a franchise to the Mahanoy City Light, Heat & Power Co.

Camillus, N. Y.—A press report states that arrangements are being made to install an electric light plant in the knife factory. Lights will be furnished to the village from this plant.

Baltimore, Md.—At the election held Nov. 4 an ordinance authorizing the issue of city stock to the amount of $1,000,000, to extend the subway system for underground wires, was indorsed by a vote of the people.

Utica, N. Y.—T. E. McGarr, Secy. State Comn. in Lunacy, Albany, writes that the contract for rewiring and fixtures at Utica State Hospital has been awarded to F. L. Frost, of Albany, for $4,889.

Middletown, N. Y.—Bids are wanted Nov. 19 for electric wiring and fixtures for Pavilions Nos. 1 and 2 at the Middletown State Hospital, as advertised in The Engineering Record.

Altamont, N. Y.—The Altamont Illuminating Co., of Altamont, has been incorporated, to supply gas and electricity in Guilderland, Knox and Altamont; capital, $5,000. Directors: E. G. Crannell, Emmett Wynderse, Eugene Sand and others, all of Altamont.

Ft. Monroe, Va.—See "Government Work."

Vincennes, Ind.—The City Council is stated to have granted a 25-year franchise to the Vincennes Electric Light & Power Co.

Alton, Ill.—It is reported that the Alton Ry., Gas & Electric Co. is planning to lay 15 miles of additional gas mains within the next few months, and to extend the present mains to Upper Alton and North Alton. J. F. Porter, Pres., Alton.

Marshfield, Wis.—See "Water."

Akron, O.—John Lamparter and Ellsworth R. Bathrick are stated to have petitioned the City Comrs. for a franchise for a steam heating plant.

Rockford, Ill.—The Council has granted J. A. Walker and Fred K. Houston, representing the Central Heat & Power Co., a franchise for an electric light plant.

Barnesville, Minn.—The citizens are stated to have voted to issue $7,000 bonds to erect a power house and install new machinery for the village electric plant.

Chisholm, Minn.—Bids were opened Oct. 31 for an electric light plant, to be located at Chisholm, from plans of Prof. John J. Flather, of Minneapolis, for John Costin, of Virginia, Minn. Bids for building were rejected, but W. I. Gray & Co. received the contract for machinery, boilers and electrical work at $8,253.

Lawrenceburg, Ky.—See "Water."

Chattanooga, Tenn.—The Chattanooga Light & Power Co. has secured the contract for lighting the city for a term of two years.

Temple, Tex.—J. T. Smither and F. E. Merrill, of Temple, are stated to have petitioned the City Council for a franchise for a steam heating plant.

Covington, Ky.—Bids are wanted Nov. 13 for lighting the streets, alleys, public places and public buildings of the entire city with improved lights for a term of 2 years. Theo. Van Hoene, City Clk.

Hattiesburg, Miss.—A charter is reported to have been granted to the Hattiesburg Light & Power Co., with a capital of $30,000. M., R. H. and H. A. Hemphill are the incorporators.

Carrington, N. D.—The Western Electric Co., of Jamestown, N. D., is stated to have secured a franchise for an electric light plant.

Sterling, Colo.—O. P. Sells, of Pueblo, is stated to have secured a franchise for lighting the city by electricity for 20 years.

Davenport, Wash.—D. M. Glasgow, of the Davenport Machinery Co., writes that bids have been asked for the construction of an electric light plant. V. Schreder, Davenport, Engr. in Charge.

Williston, N. D.—See "Water."

Halifax, N. S.—Adam Weber's Sons, Park Row Bldg., New York City, have secured the contract for constructing a coal gas plant at Halifax for the Halifax Tram Co.

ELECTRIC RAILWAYS.

Clinton, Mass.—The R. R. Comrs. are stated to have granted new locations in Clinton to the Worcester Consolidated St. Ry. Co. W. W. McKee, Ch. Engr., Worcester.

Derby, Conn.—F. H. Fagan & Co., of Derby, are stated to have secured the contract for constructing the foundations for the new power plant of the C. R. & L. Co. to be built on Riverdale Ave.; contract reported to be about $65,000.

Jamestown, N. Y.—The City Council is stated to have granted a franchise to the Warren & Jamestown St. Ry. Co.

Batavia, N. Y.—The Highway Comrs. of Batavia are reported to have granted the Union Traction Co., which proposes constructing a railway from Olcott to Batavia, by the way of Medina, a franchise on the old Lewiston Road to the village line of Batavia.

Souderton, Pa.—A charter has been granted to the Souderton, Skippack & Fairview Electric Ry. Co., with a capital of $100,000. E. S. Moser, A. G. Reiff and Wm. M. Anders are among the incorporators. The line is to extend from Souderton to Trooper, a distance of 16 miles.

Oyster Bay, L. I., N. Y.—The citizens of the Town of Oyster Bay are stated to have voted Nov. 4 to grant a right of way for a trolley line over the main highways from the steamboat landing to the railroad station, and then on to the dividing line between the towns of Oyster Bay and North Hempstead, where the proposed road will connect with the trolley, to be built in that town so as to provide a cross-island trolley road from the Sound to the Great South Bay.

Syracuse, N. Y.—The Syracuse, Lakeside & Baldwinsville Ry. Co. and the Syracuse & Suburban Ry. Co. are stated to have petitioned the Council for franchises for a system of electric roads to extend over the entire city.

Lynchburg, Va.—The Lynchburg Traction & Light Co. is reported to have awarded to the General Electric Co., of Schenectady, N. Y., the contract for equipping the plant which it proposes to establish at Rensens, on the James River. The amount involved is reported to be $60,000.

Rome, Ga.—The City Ry. Co. is stated to have decided to extend the line to Lindale, a distance of 6 miles. A power plant will also be constructed. J. B. Marvin, Mgr., Rome.

Piqua, O.—The City Council is stated to have granted a franchise to the Springfield, Piqua & Sidney Traction Co.

Vermilion, O.—It is reported that plans have been prepared for a power house to be erected here for the Lake Shore Ry. Co. F. J. Stout, Gen. Supt., Toledo.

Abingdon, Ill.—The City Council is stated to have granted a franchise to the Peoples Traction Co.

Quincy, Ill.—Bracey, Howard & Co. are stated to have secured the contract for constructing a line from Quincy to Beardstown, for the Quincy & Southeastern Electric Ry. Co.

Manitowoc, Wis.—The City Council is stated to have granted a franchise to the Manitowoc & Northern Traction Co.

Vincennes, Ind.—The City Council is stated to have granted the Southern Traction Co. (Smiley N. Chambers, Pres., Indianapolis) a 50-year franchise. The company will operate an interurban line between Vincennes and Jasper, via Petersburg, a total distance of 44 miles.

Sheboygan Falls, Wis.—The Sheboygan Light, Power & Ry. Co. has petitioned the City Council for a franchise for an electric railway. Geo. B. Mattoon, Pres., Sheboygan.

Warsaw, Ind.—The Winona & Warsaw Ry. Co. has been incorporated, with a capital of $50,000, to construct an electric line between Warsaw and the Winona Assembly grounds. Directors: J. E. Beyer, S. C. Dickey and others.

Columbus, Ind.—The Indiana Central Electric Ry. Co. is reported to have been organized, to construct an electric railway to Brownsville and French Lick. Directors: M. O. Reeves, Columbus; John B. Burrell, Brownstown, and John P. Masters, Seymour.

Brainerd, Minn.—W. K. Swartz is reported interested in the construction of a street railway.

Lexington, Ky.—The business men of Lexington and North Middletown are reported interested in the construction of an electric railway between these cities. A. Smith Bowman, of Lexington, and Charlton Low, of North Middletown, are among those interested.

New Orleans, La.—It is stated that the New Orleans Rys. Co. will expend about $50,000 in improvements.

Houston, Tex.—Major C. C. Waller and associates have petitioned the Council for a franchise on Walker Ave. and Main St. for an electric line which they propose constructing from Houston to Galveston.

Oak Cliff, Tex.—The Northern Texas Traction Co. has petitioned the City Council for a franchise to construct a line from 1st St. to Washington Ave.

Opelika, Ala.—It is reported that a company is being formed with a capital of $200,000 to purchase the electric plant of the Alabama Light & Power Co. at Opelika and build an electric freight and passenger line from there to Auburn, a distance of about 7½ miles.

Dixon, Milwaukee, Wis., *a*, 25.8 cts. per cu. yd.; *b*, $8.40 per cu. yd. Fitz Simons & Connell Co., Chicago, *a*, 24.5 cts.; *b*, $5.90. Lydon & Drews Co., Chicago, *a*, 30 cts.; *b*, $6.00. Hausler & Lutz Towing & Dock Co., Chicago, *a*, 22.5 cts.; *b*, $5.50.

Ft. Lincoln, N. D.—Bids are wanted Dec. 1 for erecting a hospital. Geo. E. Pond, Ch. Q. M., St. Paul, Minn.

Los Angeles, Cal.—Capt. Edgar Jadwin, Corps of Engrs., U. S. A., writes that contracts for dredging in Wilmington and San Diego Harbors, Cal. (bids opened Oct. 25) have been awarded as follows: To Raymond A. Perry, of Oakland, Cal., Division A which calls for the dredging of a channel at the entrance to Wilmington Harbor, Cal. (Inner Harbor at San Petro), to a depth of 20 ft. below low water, from near the outer ends of jetties to about 600 ft. north of Deadman's Island (amount available, $60,000), at 50 cts. per cu. yd., also Division B, which calls for dredging within Wilmington Harbor north of Division A, to a depth of 18 ft. at low water along principal wharfs and depth of not less than 14 ft. in approach to wharf (amount available, $40,000), at 16 cts. per cu. yd. To A. A. Polhamus, of San Diego, Division C, which calls for dredging in the ship channel across the ocean bar outside of entrance to San Diego Harbor, to a depth of 26 ft. at low water (amount available, $35,000), at 28.5 cts. per cu. yd.

Bids are wanted Nov. 26 by Capt. Edgar Jadwin, Corps of Engrs., U. S. A., at Los Angeles, for completing the jetty work at San Diego Harbor, Cal. A copy of the specifications for this work may be seen at the office of The Engineering Record.

Ft. Huachuca, Ariz.—Bids are wanted until Nov. 29 by Lieut.-Col. J. W. Pope, Ch. Q. M., Denver, Colo., for constructing 2 lavatories at Ft. Huachuca.

Ft. Lawton, Wash.—According to local press reports the following bids were received at the U. S. Engr. Office, Seattle, for the construction of 7 buildings, including plumbing, steam heating and gas piping at Ft. Lawton: F. A. Pattus, of California, $100,852; $300 less if California slate is used. W. R. Nichols, Tacoma, $110,000; Bringham & Hoska, Seattle, $117,107; Wm. Peacock, of San Francisco, $135,665, if California slate is used. Separate bids for steam heating were also received as follows: S. E. Brown, of Seattle, $10,929; Washington Steam Heating Co., $11,222; Seattle Heat & Plumbing Co., $12,555. New bids for this work have been asked and will be opened Nov. 13.

Columbus, O.—The following bids were opened Oct. 21 by Maj. Dan C. Kingman, Corps of Engrs., U. S. A., for constructing breakwaters, the extension and reconstruction of parts of east and west piers at Conneaut Harbor, O.; alternate bids were received on East Breakwater, the bids on timber crib breakwater, pier-heads, timber crib and concrete piers, being the same in each case.:

Comparative cost of entire work with changes in type of East Breakwater.	L. P. & J. A. Smith Co., Cleveland, O.	Buffalo Dredging Co., Buffalo, N. Y.	Hughes Bros. & Bangs, Syracuse, N. Y.	Geo. W. Carter's Sons' Co., Buffalo, N. Y.	Standard Cont'g Co., Cleveland, O.	Hausler & Lutz Towing & Dock Co., Chicago, Ill.	Donnelly Contr'g Co., Buffalo, N.Y.

Shreveport, La.—Capt. Chas. L. Potter, Corps of Engrs., U. S. A., Vicksburg, Miss., writes that the contract for constructing dikes, etc., in Red River at Shreveport (bids opened Nov. 1) has been awarded to Hunter & Frey, 3 Monroe St., Memphis, Tenn., as follows: 29,000 lin. ft. of piles, 28 cts. per ft.; 15,000 ft., B. M., lumber, $40 per 1,000 ft.; 1,750 lbs. spikes, 6 cts. per lb.; 750 bolts with nuts and washers, 80 cts. each; 24,000 lin. ft. galvanized steel wire strand, 2 cts. per ft.; 1,500 cords brush fascines, $4.25 per cord; 750 stakes, 20 cts. each; 26,000 cottonseed sacks, $150 per 1,000; 400 lbs. staples, 8 cts. per lb. Total, $20,362. The only other bid received was from Grigsby Const. Co., at a total of $35,588.

Ft. D. A. Russell, Wyo.—Bids are wanted Dec. 1 for erecting a pump-house. Address Lieut.-Col. J. W. Pope, Ch. Q. M., Denver, Colo.

Cheyenne, Wyo.—The following bids were opened Nov. 4, at the Treasury Dept., Washington, D. C., for a conduit and electric wiring system for the U. S. Public Bldg. at Cheyenne: Arthur Frantzen, Chicago, $3,940; Riddle & London, St. Paul, $2,967; Cheyenne Light, Fuel & Power Co., Cheyenne, $4,081.

MISCELLANEOUS.

Cohoes, N. Y.—Bids are wanted Nov. 15 for the purchase of $54,179 public improvement bonds. Miller Hay, City Chamberlain.

Baltimore, Md.—The Bd. of Estimates has passed the budget of the Park Bd. for 1903, allowing that department $351,168. This includes provision for establishing 35 new electric arc lights in Druid Hill Park.

New York, N. Y.—The following bids were opened Nov. 3 by Comr. of Docks McDougall Hawkes for about 279,500 cu. yds. of dredging on the North River, between W. 21st St. and W. 23d St.: International Contracting Co., 42 cts. per cu. yd; Morris & Cumings Dredging Co., 40 cts. per cu. yd.; R. G. Packard Co., 27½ cts. per cu. yd. (awarded).

Baltimore, Md.—Bids are wanted Nov. 12 for wharf repairs. Address Thos. G. Hayes, Pres. Bd. of Awards.

Philadelphia, Pa.—The chief engineer of the city is said to be preparing plans and specifications for the extension of the 26-ft. channel in Schuylkill River, under the appropriation of $400,000 provided in the recent Loan bill. A survey is also in progress upon Schooner Ledge to determine the amount of rock to be removed at that locality to give a 30-ft. channel.

Newark, N. J.—The proposition to issue $1,000,000 bonds for the Essex County Park Comn. is reported to have carried at the recent election.

Augusta, Ga.—At a recent meeting of representative business men and property owners a resolution was passed asking the City Council to build a levee for protection from high water.

Terre Haute, Ind.—The directors of the Honey Creek Dyke & Ditch Co. have filed a petition with the County Comrs. for the issue of $17,000 bonds to defray the expenses of proposed improvement. Frank Rigney, Chas. H. Bentley and others are directors of the company.

Superior, Wis.—Surveyors are said to be at work laying out a site for the third ore dock to be erected by the Great Northern railroad in this city. The dock will be located on Allouez Bay, east of the present docks.

St. Louis, Mo.—Ch. Engr. of Louisiana Purchase Exposition Richard H. Phillips, writes that the following bids were received for construction of Cascades, which are located north of the Main Art Building: Heman Cons. Co., St. Louis, $103,437; J. J. Lynch, $181,065; R. W. Morrison Cons. Co., $148,636; Shutt Improvement Co., $104,119; Rich Cons. Co., $135,791.

St. Louis, Mo.—The franchise granting the Missouri & Meramec Water Co. permission to construct a canal between the Missouri River at Centaur and the Meramec at the Highlands has been approved by the County Court at Clayton. Cortez A. Kitchen, Vice-Pres., is quoted as having stated that it is the intention of the Co. to increase its capital stock to $10,000,000 and push the work to completion.

Vicksburg, Miss.—The Fifth Louisiana Levee Comrs. are reported to have decided to extend the levee in the lower end of Concordia Parish, and will let out 300,000 yds. of levee work at that place.

Chattanooga, Tenn.—An ordinance establishing a park in South Chattanooga has been passed by the Lower Bd. of the Council.

Port Angeles, Wash.—Application has been made to the Council by C. A. Griggs, Frank Miller and Wm. K. Clark for a franchise to construct and maintain a dock at the foot of Oak St. The applicants are trustees of a company organized with a capital of $10,000 to build said dock.

NEW INDUSTRIAL PLANTS.

The Clinton Knitting Co., Syracuse, N. Y., is putting up a 4-story, 50x236-ft. brick factory building. The power plant will include a 150-H.-P. boiler and a 125-H. P. engine.

T. D. Kemp, Marion, Ala., is interested in an effort to establish a $25,000 or $30,000 plant for spinning yarn at that place.

The Ground Hog Plow & Foundry Co., Clarksville, Tenn., has bought the plant of Drane & Co., founders and machinists, and will enlarge same.

George Lueders & Co., 218 Pearl St., New York, whose chemical factory at South Elizabeth, N. J., was recently burned, expect to rebuild, probably on a larger scale.

The Alabama Portland Cement Co., Ltd., Demopolis, Ala., will build 60x100 and 40x90 ft. extensions and other smaller additions of structural steel. The addition to the steam plant will be 500 H.-P.

The Whatcom Falls Mill Co., Whatcom, Wash., will erect a saw mill, shingle mill, sash and door factory and wood-working plant, and is in the market for machinery.

Schloss Bros. & Co., Baltimore, Md., will erect a 7-story and basement building to have not less than 20,000 sq. ft. to the floor, and will be in the market for two 80-H.-P. boilers, two 75-H.-P. engines, dynamos, electric light plant and machinery for handling, cutting and making clothing.

One of the elevators of Geo. Bullen & Co., 332 Illinois St., Chicago, maltsters, containing about 50,000 bu. of barley, was destroyed by fire, entailing a loss of about $25,000 on barley and about $30,000 on the elevator.

The Hale & Kilburn Mfg. Co., 48 North 6th St., Philadelphia, expects, within 30 days, to invite bids for a new plant having about 200,000 sq. ft. floor space, exclusive of dry kilns and lumber storage. The company expects to install engines of about 350 H.-P., and the plant will be electrically driven, the engines being direct connected. Lockwood, Greene & Co., Boston, Engrs.

BUSINESS NOTES.

The S. Wilks Mfg. Co., 53-55 So. Clinton St., Chicago, maker of water heaters, steam generators and steel tanks, will erect a 200x150-ft. factory, partly two stories, which it expects to occupy about Jan. 1. All contracts have been let.

The Vincent Valve Co., Sandusky, O., is erecting a 42x100-ft. brass foundry and extending the iron foundry so as to give 2,000 sq. ft. additional working space. No additional power will be required.

The F. D. Cummer & Son Co., Cleveland, has just sold one of its Cummer semi-portable asphalt paving plants to The Marion County Construction Co., of Indianapolis.

The Ball Engine Co., Erie, Pa., reports the following among recent orders for engines: Cedar Rapids, Ia., Electric Light & Power Co.; Miehl Printing Press Mfg. Co., Chicago, a 300-H.-P. engine; Stromberg, Neb., Electric Light, Heat & Power Co.; Williams Coal Co., McHenry, Ky.

F. G. Street, 36 LaSalle St., Chicago, Ill., has been appointed sole agent for Northern Illinois, Indiana, Michigan, Minnesota, Wisconsin, North and South Dakota and Kansas, for the Scaife and We-Fu-Go water-softening and purifying systems, manufactured by Wm. B. Scaife & Sons Co., Pittsburg, Pa.

The New England Structural Co., of Boston, is furnishing the steel framework for the Monadnock Mills, at Bennington, Vt. Dean and Main, Engrs.

The American Blower Co., Detroit, Mich, reports recently booking a large number of orders for heating apparatus, including plants for the Lackawanna Steel Co.'s roll shop at Buffalo, N. Y.; Pittsburg, Pa., Valve Foundry Cons. Co.; Fox Typewriter Co., Grand Rapids, Mich., and the National Malleable Castings Co., Sharon, Pa., also the entire drying apparatus for the new starch factory of Piel Bros., Indianapolis, Ind.

The Sherwin-Williams Paint Co., of Cleveland, O., is equipping all its works for electric power distribution, having recently purchased for the Cleveland works three alternating-current generators of 150-Kw., 120-Kw. and 75-Kw. capacity, respectively, and about 500 H.-P. in induction motors, which will be used to drive all paint and varnish making machinery. It has also equipped the Newark, N. J., works with one 75-Kw. alternating-current engine-type generator and a number of motors and is about to install a duplicate plant at the same works. At Pullman, Ill., it is putting in a 120-Kw. alternating-current generator and one of 100-Kw., and about 200 H.-P. in induction motors. The electrical apparatus for the several plants is being furnished by the Westinghouse Electric & Mfg. Co.

Recent sales of Renold silent chain by the Link-Belt Engineering Co. include: Nine line shaft drives from motors for the new works of the Patton Paint Co., Newark, N. J.; eight drives from motors to line shafts and elevators in the new model plant which the Crompton & Knowles Loom Works are erecting in Philadelphia; and eight 60-H.-P. drives for induced-draft blowers in the new Waterside Station of the New York Edison Co. There are now sixty-one Renold silent chains in use in the new building of R. H. Macy & Co., varying in capacity from 1 to 90 H.-P.

The Pittsburgh Gage & Supply Co., Pittsburgh, Pa., reports the following among recent orders: 150-H.-P. boiler for the Lincoln Fire Brick Co., Bolivar, Pa.; 150-H.-P. boiler for the American Porcelain Co., New Brighton, Pa.; 150-H.-P. boiler for the Keystone Mining Co., Leadville, Colo., and one 35-H.-P. automatic engine for the Clearfield, Pa., Steam Laundry Co.

Trade Publications 473

The Engineering Record is published every Saturday at 21 Park Row, New York. Its opinions on technical subjects are either prepared or revised by specialists.

Subscriptions are received and single copies supplied by the International News Company, Breams Building, Chancery Lane, London.

The subscription rate is $5 a year for the United States, Canada and Mexico, and $6 for other countries in the Postal Union. Remittances should be made by check, New York draft or money order in favor of The Engineering Record. No responsibility is assumed for payments made otherwise, except those for subscriptions to the International News Company.

ANNOUNCEMENT.

Having now reached a time of life when I desire to retire from active business, I have accepted an offer from Mr. James H. McGraw to purchase The Engineering Record, feeling assured that a man so eminently successful as a publisher of technical journals will continue to maintain the paper's character. Moreover, his conduct of other publications makes me confident that the value of The Engineering Record will be much enhanced to both subscribers and advertisers.

While no longer financially interested in the journal I founded twenty-five years ago and have since conducted, I have agreed to act as an adviser in an editorial capacity, and I ask for Mr. McGraw the same cordial support from The Engineering Record's friends which has been a source of so much satisfaction to me in the past.

HENRY C. MEYER.

The statement by Mr. Meyer is so explicit that the friends of The Engineering Record need but a few words of explanation from me. The fields covered by The Street Railway Journal, The Electrical World and Engineer, and The American Electrician are such that the management with them of another paper devoted to civil and industrial engineering must be of advantage to the readers and advertisers of all these publications. I accordingly made the overture to Mr. Meyer which has resulted in the transfer to me of The Engineering Record, a paper which has won high commendation as being "always a servant of the public while a source of profit to the owner." Mr. Meyer has consented to give me the benefit of his counsel and active co-operation in maintaining the high standing of the paper, and the same staff that has executed his directions in recent years will continue to conduct its affairs. The only change that is proposed is an increase in the value of the journal in its well-established field, due to its affiliation with publications of similar standing in allied fields.

JAMES H. MCGRAW.

Columns for Buildings.

The durability of iron or steel columns is such an important element in the possible age, or lasting capacity, of the modern high building that it has once more come to be a subject of most careful and rather wide discussion. The modern steel building frame commonly carries the entire load sustained by the structure, including its own weight, and the columns are the main supporting members of the frame. Any active influence, therefore, which tends to impair the strength of the columns or to trench upon their durability weakens—and possibly fatally—the resistance of the building itself.

The danger of corrosion in iron and steel columns is no new subject of discussion, for engineering literature gives abundant evidence of its recognition at least forty years ago. Some of the most prominent forms of column section in the early days of iron and steel work were closed, thereby making it impossible to inspect their interiors and to protect them by painting. So essential, however, to its durability was the accessibility of the interior of a column considered that closed sections were permitted in bridge work for a short period only. The question was ably argued and experiences supporting both sides were cited, but the case was hopeless for the closed section and it was soon abandoned. In spite of this result for exposed columns, like those in bridges, an entirely different conclusion has been reached in connection with iron and steel columns used in buildings. Although closed columns, even in buildings, have been criticised and their comparatively short life set forth, together with all the sources of corrosion which, it has been alleged, would give them very uncertain tenure of life, they have held their own; and they form today the prevailing type of member for buildings. It is true that the Z-bar and some other forms which are not closed have been used to a considerable extent, and that some of the more prominent early closed sections have been either largely or wholly displaced, but the fact remains that the closed box column in one shape or another largely occupies the field in spite of the fact that its interior cannot be painted after the completion of the steel frame.

It is obvious that there must be some strong reason for this particular feature in structural development. It has been many times earnestly argued that the life of such a column must necessarily be limited by attacks of corrosion, both at the interior and exterior surfaces. Nevertheless, it persists, and it must be admitted that any serious danger arising from this particular feature of deterioration yet remains to be established. Undoubtedly, in a considerable number of cases, experience has shown the existence of some oxidation, but to no great extent; and in no case of good design has the rate of oxidation been shown to threaten serious danger within any reasonable period.

It is beyond question that the exposure of a bridge column is far more severe than that of practically any column standing in a well-designed building. In the latter case, compression members are usually entirely surrounded by masonry of one class or another, constituting almost complete protection even when the columns are embedded in an exterior wall, subjected to driving rainstorms.

The fact that every type of box column leads to more simple and convenient detailing than any other class of compression members undoubtedly accounts, in a large measure, for its wide adoption; but this fact alone is not a sufficient reason for the existing situation. In addition to it there is at least the strong opinion, based upon considerable experience, that no sensible amount of corrosion need be apprehended with any period affecting immediate values or those likely to exist in the near future. It may not be demonstrable that this judgment is not defective, but it is beyond reasonable doubt the most potent factor in the persistence of the closed column. Whether further developments in building construction will continue the use of that column, is a different question. Experience has shown enough to indicate, however, that when the box column or its type is displaced by another, the governing influence will be greater economy or some motive other than apprehension of interior corrosion.

The development of concrete-steel construction may indicate the field in which the improved column is to be found. Although the combination of concrete and steel has thus far been employed where greater tensile resistance than that of concrete alone has been imperative, it does not by any means follow that it may not be found advantageous for compression members, especially where a high capacity of resistance to heat of conflagrations is desired. Nearly all steel columns in buildings are enclosed in terra-cotta or masonry of one kind or another, either to secure a more ornate appearance or protection against high temperatures caused by fires. It is but a short and easy step to secure both of these results by a suitable combination of concrete and steel bars other than the usual steel compression member. In a number of cases the interiors of steel columns have been filled with concrete with an exterior covering of brick or other similar fire-resisting material. Abundant experience has demonstrated the efficiency of concrete protection against corrosion when the concrete is suitably mixed and put in place. A relatively wet mixture is needed so that voids will not exist and also that the surface of the steel may be covered with a wet cement coating. When steel is so completely embedded in a relatively large mass of concrete it receives rigid lateral support, enabling it to act in compression like a short block rather than like a long column. Under such circumstances each square inch of steel section may properly be assumed to carry much more load than when under conditions requiring the use of a column formula. Again, the concrete is so circumstanced as to sustain a large load itself, probably not less than 40 to 50 tons per square foot. Indeed, by suitably reinforcing the surrounding concrete with light steel sections, such as wire, the concrete's loading could probably be increased to 70 tons per square foot, without violating the canons of good practice. This development in the design and construction of compression members would possess a number of material advantages, including economy. The less expensive shapes of steel could be employed under much higher unit loads and their combination with concrete would result in a solidity of section making the compressive resistance of that material available as well as attaining complete fire-resisting capacity.

The New East River Bridge Fire, a carefully prepared account of which appears on the following pages, adds another large item to the already heavy bill for the careless use of matches, to which smokers seem especially addicted. The loss in this case, while very great, is not nearly so great as the early newspaper reports indicated. It seems hardly possible to make discipline rigid enough or to secure a sufficiently watchful oversight to entirely eliminate this danger. Nevertheless, every precaution should be taken to guard against the carelessness or maliciousness of the irresponsible individual on whom can fall but a small share of the burden of the damages.

The Fire on the New East River Bridge.

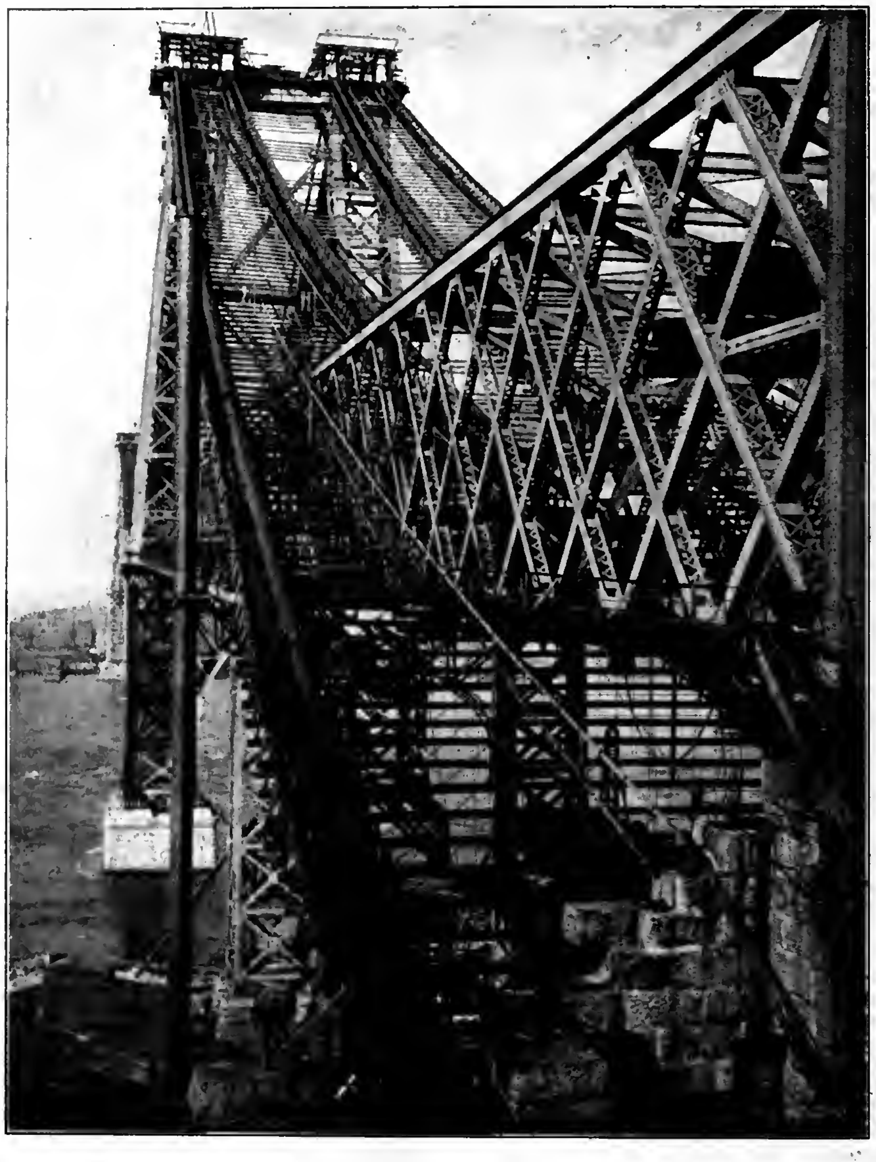
At 4.35 P. M., November 10, before all the workmen had left for the night, a fire was discovered on the temporary wooden working plantform at the top of the west main tower of the new East River Bridge, officially known as the Williamsburg Bridge, Greater New York. The flames spread rapidly and consumed all of the platform on the south side of the tower and pretty thoroughly destroyed that on the north side. The top of the tower has a skeleton platform of massive steel girders with solid steel floors under the cables. On this framework had been built the 25x100-foot wooden working platform, and above it a heavy wooden framework carrying shafts, pulleys and other machinery for the cable construction. There was about 53,000 feet of timber near the saddles, all of which was thoroughly dried and much of it saturated with oil, grease and the inflammable mixture used for water-proofing the cables. There were also two or three barrels of oil and a barrel of paint there. Consequently when a fire was started by a match dropped as the workmen were leaving, it rapidly spread and made a fierce blaze with heat so intense in places as to warp and twist heavy steel and burn and partly fuse small metal objects like nails. The great heat weakened the cables of the temporary falsework bridge, on which the main cables have been built, so that they broke and caused the collapse and destruction of this footwalk in its two spans adjacent to the west tower. Besides this damage was done to the lower platforms and the contractors' plant at this tower.

It was at first reported that three lives had been lost but this is not confirmed by later reports. The preliminary examinations which have been made up to the time of going to press do not indicate that the permanent structure has received serious damage or is in any way endangered; but some repairs will be necessary which may be of a delicate nature and slow to make, and the extremely difficult work of removing the wreck of the temporary foot bridge will be costly and will delay work which was ready for immediate prosecution on the west anchorage pier and on the suspended trusses of the main span. The contractors' engineer thinks that the direct loss may be about $50,000 and the delay two months, if there is no more serious injury to the main cables and tower top than is now indicated.

Over the center of the tower each cable is supported in the 19¼x16⅝-inch groove in the segmental top of a 34-ton cast steel saddle 19 feet long and about 5 feet high. The wires of the cable are here arranged in a nearly rectangular, solid cross-section, while beyond the saddle they are wrapped with wires and gradually brought to a circular cross-section. Up to about 20 feet from each end of the saddle each cable, excepting No. 1, had been permanently enclosed in duck wrappings and cylindrical steel shells. The 40-foot lengths of cables between the ends of the shells were not protected, and the flat steel cover plates had not been bolted over the tops of the saddles, so that the cable wires there were fully exposed and those on the surface were, doubtless, heated red hot, as is indicated by the scales and discoloration. Where the sides and bottom of the cables were enclosed in the saddle groove, the 3 inches of solid metal protected them, and so, while it may be found necessary to replace some of the upper outside wires, it is not likely that a large proportion of them will need attention. As the wires are all spliced with sleeve nuts new pieces can be inserted without weakening the cables, and the chief difficulties will be in getting hold of them and in adjusting their tensions. The main saddles were all temporarily set 3 feet nearer the anchorages than their final positions, and secured there by wooden braces, which were burned away, thus allowing all the saddles to move suddenly forward 8 inches on their rollers, and the cables to sag about 16 inches in the center. This has not apparently injured the tower and will not seriously interfere with the adjustments of the bridge, because when the saddles on the other tower are released and the final loads applied the cable will assume its intended catenary form.

The middle unfloored sections of the four transverse girders in the saddle platform are about 7 feet deep and 42 feet long with pairs of 6x6x¾-inch angles in the flanges, and in one of them the top flange was warped and twisted. Some of the floor plates and braces, also, were injured, but the damage did not appear to be so serious as to require the removal of the members when examined by a member of the staff of The Engineering Record. Most of the suspender cables for the support of the trusses had been attached to the main cables between the towers, and, as they enclosed the temporary foot bridge, they received it when it fell, thus sustaining severe impacts which may have injured them. Otherwise little damage appears to have been inflicted upon the permanent structure; but the condition of the tower and main cables cannot be accurately determined until very careful measurements shall have been made. Although the foot bridge had nearly served its intended purpose, it will have to be rebuilt in a modified form. Its original cost was about $150,000 and the salvage from it will be nearly as great as if it had been removed in the manner intended. Probably it will not be necessary to replace the falsework on the towers, but there will be loss of salvage on it and considerable loss of machinery, tools, and materials on the towers. The two northerly main cables are apparently uninjured.

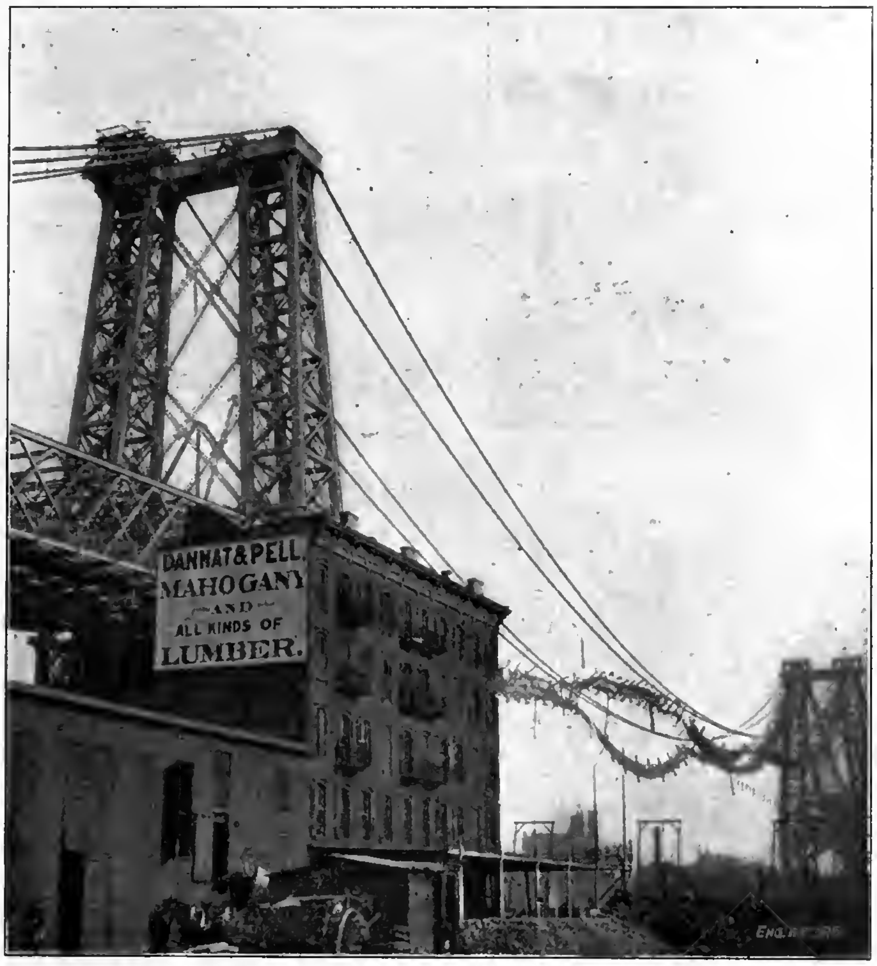
The top of the tower was accessible by wooden stairs between its columns on the north side and by the four lines of footwalks on the temporary suspended spans from the New York anchorage and the Brooklyn tower. When the fire was first noticed, there were about fifty men on or near the top of the tower, who immediately attempted to extinguish it, but being without apparatus, having little water and being unable to get very close to it, on account of the small area of platform, they were unsuccessful. They were reinforced by men coming back from the Brooklyn tower and were cutting away the wood work of the temporary bridge to prevent the spread of the flames when they were driven off by the danger of sudden displacement of the saddles and main cables, which soon afterwards occurred. They lowered ropes to the water 340 feet below for fire hose from the fire boat, but the hose could not be brought up this way and was carried up the stairs by the firemen, with great difficulty. The height was so great that two engines were unable to force a stream to the top, and when a third engine was coupled on the increased pressure burst the hose. Finally two engines succeeded in sending a weak stream to the top of the tower and one nozzle on the north side



Tower, Footbridge and Shore Span from Anchor Pier before Fire.

played feebly across to the south side but was not effective.

During the progress of the fire there were explosions of the barrels of oil and paint on the platform, and many large and small pieces of red hot steel and blazing timber fell to the river and the ground, but neither the men on the tower nor the spectators were injured. The falling foot bridge made navigation under the bridge dangerous for several hours and few boats attempted the passage. One man on a fire boat was seriously injured by a hot falling bolt, and planks and bolts fell on other boats, injuring them but not harming any person. The great height of the fire and the rain of glowing fragments made a brilliant spectacle, but the flames did not appear very large from the ground. The fire lasted about five hours. The following morning a secondary fire broke out on the platform at the roadway level of the approach span trusses, but it was quickly extinguished and its effects were not serious.



Looking toward Brooklyn after the Fire.

When the flames had subsided somewhat, Assistant Engineer K. L. Martin and two chiefs of the fire department made a very perilous ascent of the stairs through the shower of falling pieces of red hot steel and blazing timber, to the top of the tower. While they were there the flames threatened the stairway and they had much difficulty in driving back the fire and extinguishing it with a small quantity of drinking water. These men and the others who risked life and limb in fighting this unique fire deserve unstinted praise for their courage.

One of the men was escaping from the burning tower to the Brooklyn side and was in the center of the south foot bridge when its cables broke and the western end of it collapsed. He clung to the ropes and managed to make his way over the adjacent cross walk to the north foot bridge and thence to safety.

One of the accompanying illustrations is a view taken shortly before the fire, and the others are views taken the day after the fire for The Engineering Record by the photographer of the Pennsylvania Steel Company. The pictures give a clear idea of the most conspicuous damage, the wreck of the foot bridge and the destruction of the tower falsework. The main span of the foot bridge is festooned in the permanent suspenders for the trusses, and the shore span has fallen on the approach span, and is supported by it with its own loose cables sagged far below the original position, between the end of this span and the anchorage pier, where the last of the approach spans has not yet been erected. Part of the falsework remains on the north side of the tower and gives some idea of the character of the duplicate construction on the south side, which surmounted the saddles there and was wholly consumed.

The cables are numbered in succession from the south side of the tower. No. 1 had the steel casings completed up to the saddles and they are still in place and probably afforded considerable protection to the wires. The other cables were wrapped with the water-proofed duck up to the saddles; this burns persistently with a moderate flame and was consumed where exposed beyond the ends of the steel casing. Cable No. 2 was injured most, and cables Nos. 3 and 4 were injured least. Some of the discolored wires in the surface of the cables have been cut out for tests which will determine whether they have escaped permanent injury. Each wire is about 3/16-inch in diameter and when straightened was immersed in molten zinc, at a temperature of 800 degrees Fahrenheit. It is believed that a considerably higher temperature could be sustained by the wires without injury, and that the heat from the flames of wood and oil some distance away and chiefly above the cables has not done them much damage. Each wire has an ultimate strength of 6,000 pounds and a working load of 1,500 pounds. The new pieces of wire which it may prove necessary to insert can be stressed to any required tension by the splice nuts, and the tension can be estimated by the expert workmen to within about 10 pounds; but if necessary it can be determined by measuring with a dynamometer the force required to produce a given deflection in a measured length, as has been done by Mr. Hildenbrand in other cases of wires spliced into cables.

The saddles for the foot bridge cables show by their appearance that they have been heated to redness, and, doubtless, the cables that they supported were also red hot and therefore much weakened at that point. Each cable had a normal tensile strength of 624 tons and a factor of safety of 3.7 under the load of the foot bridge. If this strength had been reduced 66 per cent. by the fire they would still have supported the foot bridge, but could not have supported a large extra load or sudden shock. Before the fire the main cables, weighing with their suspenders about 1,000 tons each between towers and having a tension of about 1,500 tons at the top of the saddles, were very close above the foot bridge floors. When the saddles moved and lowered the main cables 16 inches, of course very heavy sudden loads were imposed on the foot bridges, which, it is believed, snapped their cables where they rested in the saddles, the stresses at these points being increased about 15 per cent. As nearly as could be seen from the tower, one of the broken cable ends appeared to have been snapped off short, and another to have been elongated like a specimen broken gradually in a testing machine. The saddles of the main cables were in equilibrium except for the stresses caused by temperature and by the incomplete loading. Timber struts were advisedly used, instead of iron, to keep the saddles temporarily on the anchorage side of the tower, because in their final removal they could be partly cut away and then permitted to crush gradually and allow the saddles to move slowly into the final position. The saddles will not need to be moved back to their original positions.

The total cost of the Williamsburg bridge and approaches, including land, is estimated at nearly $20,000,000, about $9,000,000 being for the structure itself. The main span is 1,600 feet long between centers of towers, the longest in the world. The steel towers are each supported on two masonry piers with pneumatic caisson foundations carried down to a maximum depth of 107½ feet below water level, rise about 335 feet above mean high water and support four main cables about 18 inches in diameter and 3,000 feet long. Each cable weighs 2,500,000 pounds, has an ultimate strength of 50,000,000 pounds, a working load of 10,000,000 pounds, is composed of 7,696 straight wires and cost about $350,000. The suspended span, which with part of the Brooklyn approach is all that remains to be built, has two trusses 67 feet apart and 40 feet deep on centers, with two decks to accommodate two railroad tracks, four trolley tracks, two roadways, two sidewalks and two bicycle paths, and will cost about $1,120,000.

The main cables were built from temporary foot bridges about 3,000 feet long, suspended from four cables reaching from anchorage to anchorage, adjacent and approximately parallel to the main cables. Each temporary cable was composed of three twisted steel wire ropes 2¼ inches in diameter, was first carried across the river and dropped to the bottom and afterwards lifted bodily to the tops of the towers. These cables carried four double deck wooden foot walks in the planes of the main cables and connected by cross walks. After the 37 strands of each main cable were completed, they were lowered several feet in the center, the upper decks of the foot walks were removed and a single wide platform was laid over the two narrow walks which were on each side of the center line of the bridge. At the time of the fire, the wind-brace cables were being removed preliminary to taking down the foot walks.

The shore spans of the bridge were described in The Engineering Record February 12 and 19, 1898, the cable specifications were printed November 18, 1899, the design of the approaches described May 12, 1900, the design of the temporary foot bridge October 27, 1900, the suspended span May 4, 1901, the stretching of the temporary cables September 14, 1901, and the cable-making May 3 and October 25, 1902.

Mr. L. L. Buck, M. Am. Soc. C. E., is consulting engineer, and Mr. O. F. Nichols, M. Am. Soc. C. E., is engineer in charge of the New East River Bridge. The John A. Roebling's Sons Company is the contractor for the cables: the Pennsylvania Steel Company has the contract for the approach viaducts and the suspended trusses, and was in readiness to commence the erection of the latter when the fire occurred; Messrs. Shanly & Ryan are the contractors for the anchorage on the New York side, on which the wreckage of some of the temporary works fell; and Edward Smith & Company are furnishing their durable metal coating which is being applied to the cables for water-proofing. The New York tower of the bridge was erected by the Terry & Tench Construction Company. Mr. Wilhelm Hildenbrand, M. Am. Soc. C. E., is the engineer for the Roeblings.

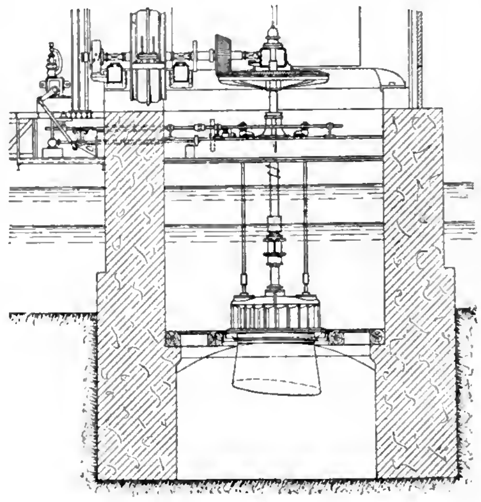
Recent European Water-Power Plants.

The handicap under which European industrial enterprises requiring power are compelled to operate because of the high price of fuel as compared with the prevailing American figures, has naturally encouraged the development of Continental water powers where there is a lower effective head than is considered of use in this country, and where the conditions are such as to call often for apparatus and methods not generally employed here. A description of several such plants was recently given in a paper read before the Engineers and Architects Association of Zurich, by Mr. Zoelly, the director of the firm of Escher, Wyss & Company, of Zurich, from which the following notes have been taken:

The first plant described was that of the municipal light and water works at Schaffhausen. In this case it was proposed to replace the existing installation of three Jonval turbines, developing from 200 to 260 horse power under heads varying from 11½ to 14¾ feet, by the same number of Francis turbines, having a guaranteed capacity of 350 horse-power at

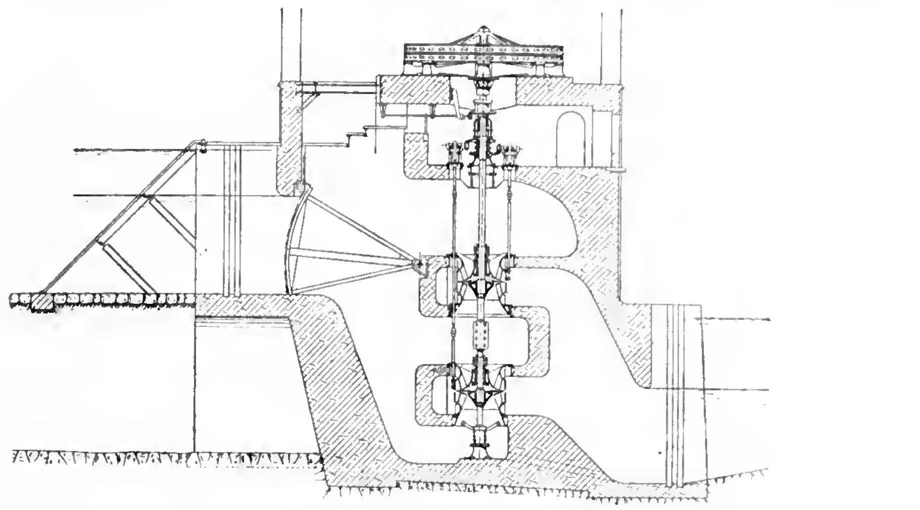


SCHAFFHAUSEN POWER PLANT.

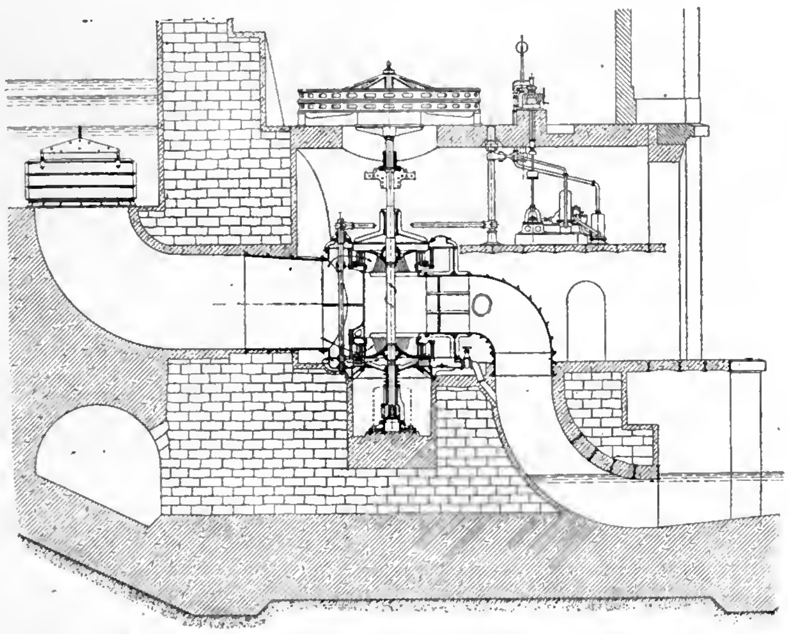
12½ feet head. The volume of water available for each turbine was from 270 to 300 cubic feet per minute. Because of the existing electrical plant it was desirable to retain the former number of revolutions per minute, which was 60, and also to use the former turbine foundations, which necessitated an outer diameter of 80 inches and a draft fall of 40 inches. A vertical section of the wheel pit is shown in the illustration. The guide ring is 25½ inches high and has 24 openings, while the runner has 20 blades, its diameter increasing toward the bottom. Between the guide ring and the runner is a regulating gate of the Zodel type, controlled by a hydraulic regulator, for which hand regulation can be substituted at any time. The shaft is vertical, and has four bearings, the upper one being a ring suspension bearing of the usual type, which takes the whole weight. Because of the radial direction of the entering water and the short draft, the pressure on the bearings is not great. Tests of these turbines show 430 horse-power developed under 12½ feet head, and an efficiency of 86.6 per cent. at full load, 82.6 per cent. at three-quarter load, and 77 per cent. at one-half load, in spite of the limitations under which they were designed.

Where the available head is between 13 and 50 feet, and it would be inadvisable to couple a simple turbine direct to the dynamo because of the small number of revolutions per minute, it is frequently found desirable to put several turbines on the same shaft. This has been done in the second installation of the Geneva city power station, at Chèvres. There there are five older conical-turbines, of 800 to 1,000 horse-power at 80 revolutions, and 10 recently installed double centrifugal turbines of 900 to 1,200 horse-power at 120 revolutions. The head varies from 14 to 26½ feet and the volume of water from 4,230 to 42,300 cubic feet per second, these fluctuations occurring at times with but little warning. Each of the older units consist of two turbines on a vertical shaft, each turbine being composed of three wheels, through which the water flows from the upper side to the lower. The wheels are of different diameter, and their blades are differently set, as the lower one is designed to work alone at maximum economy under the higher heads. The step-bearings of these have to support the water pressure as well as the weight of the working parts, so that it is necessary to supply them with oil under 75 pounds pressure.

The new turbines are of different construction, as shown in the illustration. They have each two wheels, of which the lower one is designed to work alone under the high heads, and there are two sets of guides for each wheel,



Chèvres Power Plant.



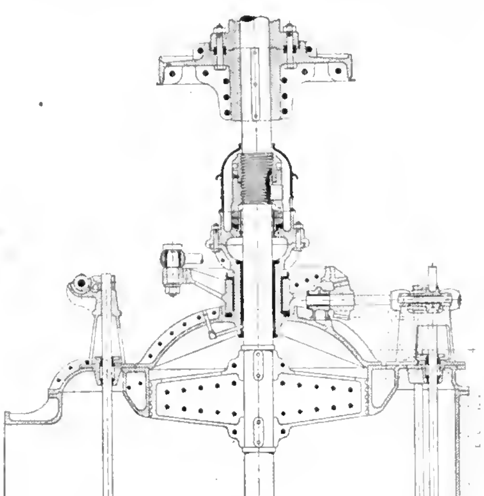
Arrangement of 1,500-Horse-Power Turbines, Lyons.

one above and one below. The water flows in a direction parallel with the axis into each wheel both from above and from below, and leaves at the circumference in a radial direction. The wheel-casing on both the upper and lower turbines is so arranged as to admit more pressure to the under side than the upper, in this way so far balancing the pressure that an overhead suspension bearing may be used.

The speed is controlled by cylinder gates placed around the runner, each being in two parts and operated by a hydraulic governor. Turbines of this design are held to have the advantage of developing a high speed at low heads, are easily balanced and regulated and are of high efficiency, but they are of somewhat complicated construction. The setting of the turbines is entirely of cement and steel construction, as may be seen by reference to the drawing. The admission gates are of the pattern known in this country as the Tainter gate. This gate has a sylindrical surface, the convex side towards the incoming water, and is pivoted at the axis of the cylinder, which lies in the horizontal plane, somewhat above the bottom of the head race. It is raised and lowered by a cord or chain working over pulleys, and has the advantage of requiring but little power to move it.

A notable example of the employment of the Francis turbine is the power station of the city of Lyons, where there are 22,000 horse-power installed, forming one of the largest plants in Europe. The water is taken from the river Rhone, above Lyons, by a canal 11½ miles long, the power house being about 1½ miles from the lower end. The upper part of the canal forming the head race is 8¼ feet deep in the shallowest part, and varies from 197 to 344 feet wide. Its construction was a considerable undertaking, as the bottom is about on a level with the surrounding country. One bank was formed by a natural slope, but the other had to be filled in, the earth taken from the cut necessary for the tail race being used for this purpose. The labor was increased by soft ground and insecure foundations, it being necessary to concrete a considerable portion of the head race bottom just above the power house. The canal was intended to serve for navigation and irrigation purposes as well as water power, and therefore the natural conformation of the land was taken advantage of to make a basin of considerable size about the middle of its length. Here a spill-way was placed, in order to prevent an undue rise of the water. There is also a lock adjoining the power house to allow boats to pass up the dam. The available head varies from 33 to 39 feet, at times of extreme high water falling as low as 26 feet for a short time. The present installation consists of eight 1,250 horse-power turbines, three of 250 horse-power, and two of 1,500 horse-power, six units of the latter size being now under construction. All the large turbines are coupled to alternating current dynamos directly above them on the same shaft, the 250 horse-power units delivering exciting current for the alternators.

The water is led to each turbine through a separate penstock built into the masonry, and the admission is controlled by a lifting bell over each opening, which is raised or lowered by a rope and pulley. The power house has three stories, the lower serving for the turbines, the second for the regulator connections, the suspension bearings and the oil pumps, and the upper one for the generators and the hydraulic governors. The floors are of cement and steel construction. The 1,250 horse-power turbines, which were the first installed, are run at 120 revolutions per minute, and are of the Francis type. They have a conical wheel at the end of a vertical shaft, working in a cast-iron casing which supports the guides.



1,250-Horse-Power Turbine, Lyons.

These, as well as the turbine blades, are divided into three annular portions by cast partitions, the openings of which are furnished with gates so that the amount of water admitted may be varied according to the height of the available fall. The downward pressure on the wheel is partly balanced by a disk revolving in the upper part of the casing, and the remaining part of the load is carried by an elaborate self-oiling suspension bearing just above it.

The 1,500 horse-power turbines are of later design, and differ considerably from the foregoing. They are of the double type, this form being adopted in order to give more power, and because the variations in the available head proved to be larger and more frequent than had been anticipated. The two wheels of each turbine discharge into a common draft tube, built partly of steel and partly of cement reinforced with steel, leading to the tail race. The regulation is by Fink swinging gates, worked by a servomotor under oil-pressure. By virtue of their arrangement the wheels are hydraulically balanced, and in order to neutralize the weight of the turbine as well, the disk of the lower wheel is allowed to receive the water pressure, while that of the upper wheel is perforated, so that the suction of the draft tube acts on both sides. In this way the pressure acting on the main shaft is so much reduced that a small suspension bearing of ordinary design is ample to carry it. These turbines, working under a head of from 33 to 39 feet, have shown an efficiency of 76 per cent., but this is not to be regarded as their maximum. The wheels are described in greater detail in the "Zeitschrift" of the Society of German Engineers.

The Municipal Testing Laboratory at Philadelphia is stated, in the annual report of Geo. S. Webster, chief engineer of the Bureau of Surveys, to have resulted in securing to the city the performance of the necessary testing work at a cost of about one-fifth what would have been charged by a private laboratory.

Examinations for Civil Service positions are announced as follows by the Municipal Civil Service Commission of New York City: Topographical draughtsman, sixteenth grade, Monday, December 1, at 10 A. M.; annual compensation, $3,000 or more. Assistant engineer, tenth grade, Wednesday, December 3, at 10 A. M.; annual compensation not exceeding $2,100. Leveler, fourth and fifth grades, Friday, December 5, at 10 A. M.; compensation more than $1,050, but not more than $1,350 per annum. Assistant engineer, Rapid Transit Commission, fourth grade, Monday, December 8, at 10 A. M.; annual compensation not exceeding $1,200. Building inspector of masonry and carpentry, fourth grade, Wednesday, December 10, at 10 A. M.; annual compensation not exceeding $1,200. The receipt of applications in each case closes a few days before the date set for the examination. For further particulars, address the secretary of the commission, Mr. S. William Briscoe, at 61 Elm Street.

The Equipment of a Modern Paving Brick Plant.

A paper by Willard D. Richardson, Cleveland, O., in Volume IV. of the Transactions of the American Ceramic Society, October, 1902.

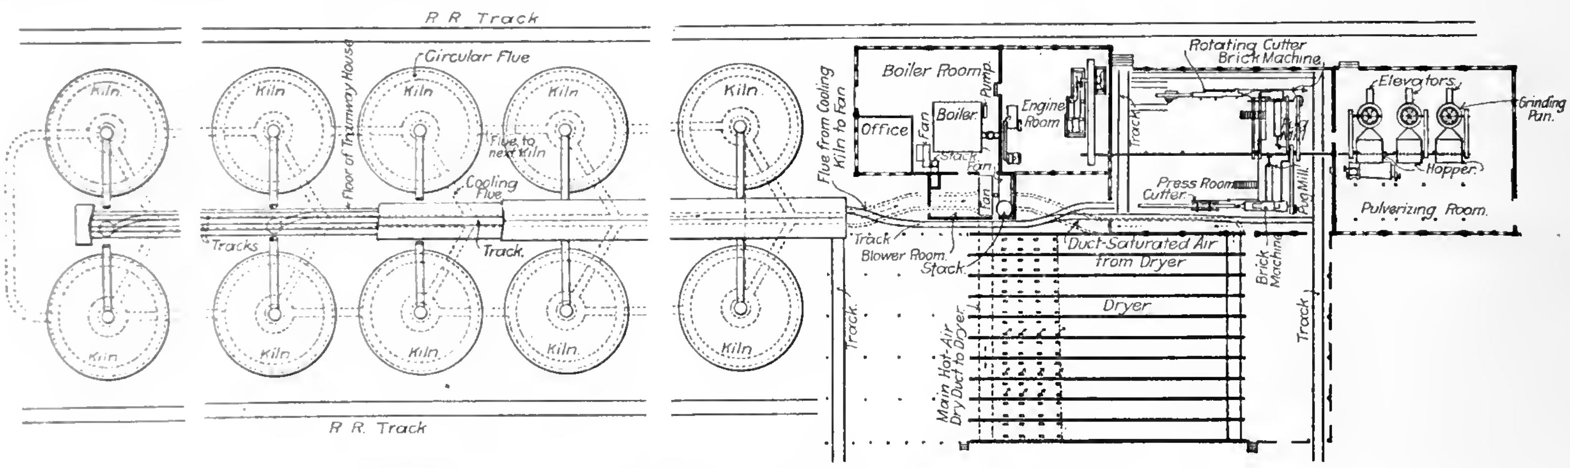
In planning a brick plant, due consideration must be given to the special purpose of the proposed establishment, and to the special local conditions, such as the size and topography of the site for the building, the location of the clay and the railroad, etc. These local conditions must always determine to a greater or less degree, the general plan to be adopted.

The plans described are for a paving brick plant, about one mile south of Cleveland, Ohio. The shale to be used is situated above the level of the factory, to which it will be conveyed by a gravity railway. The direction from which the shale must come is directly opposite to that from which must come the spur from railroad for receiving coal and shipping brick. These facts necessarily influenced me in settling upon the general arrangement of yard.

The cars of shale enter the factory at an elevation of twenty-two feet and are dumped into hoppers built so that one man, by operating gates from below, can attend to the feeding of three or four drypans—or the shale can be dumped outside of the hoppers in the storage machines, for convenience in receiving and discharging clay.

The brick machines are the standard auger type, largest size, with automatic cutting tables and separating belts. In this special factory, one machine is to be used for making sewer and building brick, not repressed, and the other for the large size paving block demanded in this market. With the latter machine is one double die repress. The cars, loaded from the separating belt or repress, pass to a transfer track, just back of the machines at the rear of the press room, and thence to the receiving tracks of the dryer.

The power is transmitted to machinery by a line shaft extending through the center of the building and supported upon cast-iron columns with brackets cast upon them. The boiler room is situated at the lower end of dryer, at the head of the kilns, for convenience in receiving fuel and in furnishing steam for blower engine, and so as to utilize the combustion gases for dryer, if desired, and also exhaust steam. The boilers, of the water-tube type, have induced artificial draft, being connected so as to be operated by separate fan discharging into atmosphere, or by the dryer fan discharging into dryer.



GENERAL PLAN OF PAVING BRICK PLANT AT CLEVELAND, O.

DESIGNED BY WILLARD D. RICHARDSON.

room and fed to pans, in stormy weather, in the usual manner. These pans are placed in the pulverizing room back of the press room in a row on a line parallel with the general progressive movement of the clay and brick, so that the clay is easily conveyed from the screens to a central hopper for feeding to pug mills.

The simple stationary inclined screens are used, the clay being elevated from pans to sufficient height to permit of these screens being twenty-four feet long. The width of each screen is six feet, and in order to secure a uniform distribution over the surface of so wide a screen, the clay is dumped from elevators into an U trough conveyor having an adjustable slot in bottom, over the screens. The tailings from the screens pass to the shale hoppers instead of directly to the pans. The screened clay is collected at the foot of the screens by a conveyor that carries it to the hopper above the press room.

The hopper for fine clays is in an upper room separated from the press room by dust-tight partition and floor, the lower part of the hopper projecting through this floor into the press room, and above and between the pug mills. This hopper is also an automatic feeder, supplying, when in operation, a constant uniform quantity of clay to the pug mills, making uniform tempering an easy matter. The capacity of this hopper and feeder is sufficient for the two largest pug mills. These pug mills are placed back to back, at right angles to brick

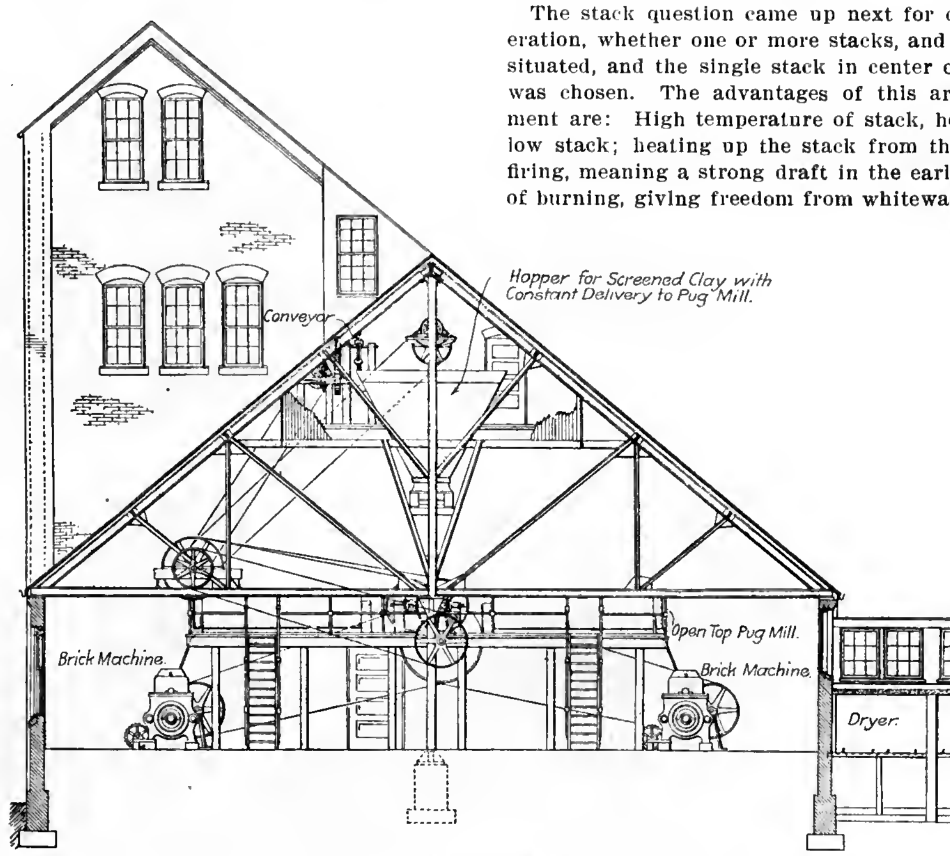
The engine room, between the boiler room and the press room, contains a 250-horse-power Corliss engine for running the factory, and an automatic engine for running generator, dryer fans and machine tools. The machine tools situated in engine room are lathe, planer and drill press. The generator is for running motors that operate fans for induced draft of kilns and also for lighting. The buildings are practically fire-proof, the walls of brick and the roof framing of steel. This roof frame is covered with matched pine one and three-fourth inches thick and upon this, slate or roofing tile. The underside of the wood, between the rafters, is to be covered with two coats of lime whitewash, or other fire resisting paint. The floors are mostly of concrete and nearly all posts and beams of iron.

The dryer, constructed for the most part in the usual manner, consists of a series of tunnels separated by brick walls, each tunnel containing two tracks 100 feet long. The receiving tracks are twenty-three feet long and the cooling tracks forty-four feet long. The construction of the dryer is absolutely fire-proof, the roof, of course, being the special feature. Upon the top of the division walls, which are six feet and nine inches between centers, is constructed four inches of concrete, made from vulcanite cement, gravel and coal cinders, reinforced with a net work of iron strips. Upon this concrete is a course of hollow book tile laid in cement, and upon the tile is a gravel roof, the felt being stuck to the tile. This roof slopes from the receiving end of the dryer to within ten feet of the discharge end, one-fourth inch to the foot, this being the slope of the track in the tunnels. The last ten feet of roof at the discharging end is built up to slope backwards, forming a valley. In this valley are openings into 4-inch conductor pipes laid in each wall, and passing downward to the sewer pipe drain below.

The special feature in addition to the roof construction is the slope of one-fourth inch to the foot in the tracks from the receiving end, the last ten feet being level, and the method of moving the cars through the tunnels. The cars are coupled together automatically when placed in the dryer, so as to insure no break in their ranks as they move by gravity down the decline. At the bottom of the decline is a device for braking and stopping the cars. By throwing a lever just outside the entrance of the tunnel, the forward car on any track is disengaged and the car back of it is blocked. After the forward car is removed, the lever is reversed and the other cars let down and blocked, each car being uncoupled automatically about ten feet from the end of the dryer. Thus one car is always free to be removed from dryer, and a car can be put into dryer at receiving end without the necessity of pushing other cars.

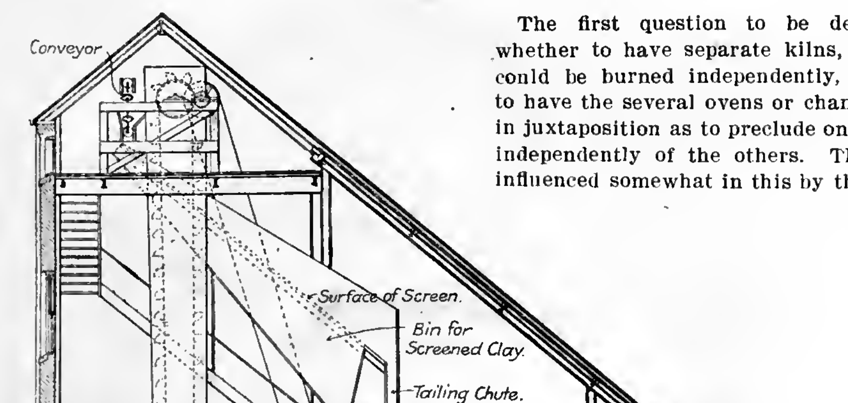
The heat for drying is obtained from cooling kilns by means of a fan, the distribution of heat being in the usual manner. The special feature, however, is that the saturated air is removed from the dryer through an underground flue by means of a fan coupled with the fan that furnishes the hot air, both fans being upon the same shaft and driven by the same belt, the driving pulley being in the boiler room upon the shaft extending from the engine room.

In making plans for a brick plant, especially for the manufacture of paving brick, one's chief study must be in designing the kilns for burning. The kiln for this purpose must have the following features: Down draft; uniform distribution of heat; durability, costing little for repair, and economy of operation, saving fuel, labor and time, and so constructed as not only to utilize waste heat, from cooling kilns for transmission to dryer, or for heating air for combustion in kiln furnaces, but also it must utilize the waste heat escaping from the hot burning kilns in heating up other kilns. In other words, it must have the advantages of the continuous kiln, without its disadvantages.



Section of Brick Machine Room.

The first question to be determined was whether to have separate kilns, each of which could be burned independently, if desired; or to have the several ovens or chambers so placed in juxtaposition as to preclude one being burned independently of the others. The author was influenced somewhat in this by the judgment of friends who have had large experience with continuous kilns, and also by the fact that in building separate kilns, he would be following along the line of his previous practice, and would feel more confident of obtaining the desired results.



Section of Pulverizing Room.

Having decided upon separate kilns, the next point to determine was the form of the kiln, whether round or rectangular. Experience with both forms enabled the author to decide at once in favor of the round kiln, chiefly for two reasons: Because the round kiln is less expensive in first cost, and especially in repairs; and because it gives better distribution of heat and fewer underburned brick.

The stack question came up next for consideration, whether one or more stacks, and where situated, and the single stack in center of kiln was chosen. The advantages of this arrangement are: High temperature of stack, hence a low stack; heating up the stack from the first firing, meaning a strong draft in the early part of burning, giving freedom from whitewash and shortening the time of burning; a kiln of larger diameter, with hard brick to the center. The disadvantages of stack in center of kiln are: Inconvenience in setting, and space occupied in kiln. These disadvantages have not been found so great as at first thought. The stack in the center of a large kiln is not much in the way, in fact, hardly more in the way than a stack in any other place. The space occupied in the kiln is, for a thirty-foot kiln, only about two per cent. of the inside kiln space and for a thirty-six-foot kiln, about one and one-half per cent. These are thirty-six foot kilns, with twelve furnaces to each kiln, and there is really no grate surface at all. The fire-hole is two feet wide, without grate bars. The firing door is covered in the usual manner with a fire clay slab, reinforced with iron bands. The coal is thrown upon a coking table, made partly of cast iron and partly of fire-clay tile and shoved down upon the fire just before a fresh supply of coal is added.

The special feature of the kilns for this plant is the system of utilizing the hot gases escaping from the burning kilns for heating up other kilns, and likewise of using the cooling kilns for heating the air for combustion. To accomplish this the kilns are connected by an underground flue, extending from the center of each kiln to a circular distributing flue in the next kiln ahead. This circular flue is in the hub of the kiln, with openings into each fire box, adjustable by dampers. The movement of the gases is induced by a fan connected to the stack of any kiln by a cylindrical steel flue. The fan is portable, being erected upon a car moved along an elevated track between two rows of kilns and operated by an electric motor directly connected.

The author calculates in this manner to be-able to draw the heat from a hot kiln through at least two other kilns and that by the time that the kiln under fire is finished, the kiln just ahead will be partially or wholly incandescent, so that heavy fires can be put into the furnace at once. There will thus not only be a saving in fuel, but a considerable saving also in the time of burning.

The Damage to the Williamsburg Bridge.

The fire upon the Manhattan tower of the Williamsburg Bridge in New York City is described upon another page of this issue. The official report of the fire by Mr. O. F. Nichols, Engineer in Charge, to Bridge Commissioner Lindenthal, describes the damage done as follows: The blocking which retained the saddles in their position back of the center of the tower burned away in all cases, and the three southerly saddles moved forward about 9 inches and the northerly saddle D moved forward 5 inches, toward the river. The movement of the saddles lowered the cables on the channel span and precipitated a greatly increased load on the foot-bridges, the cables of which parted under this stress, the cables of the south foot-bridge parting first. Examination of the wires in these cables shows that the wires were elongated in breaking, their strength being considerably decreased by the heat to which they were subjected, although this heat was not sufficient to burn off the galvanizing for more than a few inches each side of the break.

In falling, the land span of the foot-bridge, on the Manhattan side, fell on to the end spans, the easterly cables of the foot-bridge were slacked off, and the land span on the Brooklyn side dropped some 10 or 15 feet, and the river span, west of the Brooklyn tower, fell away from the main cables in the same way, while the balance of the foot-bridge cables toward the Manhattan tower were caught in the loops of the suspender ropes and were thus prevented from falling into the river. The foot-bridge is, therefore, practically a total wreck. An examination at the top of the tower shows that the wires of the C and D cables are practically uninjured, the filling compound in the saddles not having been melted out.

The wires of the A and B cables, on the other hand, were subjected to intense heat, which melted out all the cable protecting material in the saddles and burned off the slushing oil to some depth into the cables for the whole length of the saddles. This depth cannot be exactly ascertained, but it is probable that it extends from 3 to 5 wires deep in each of these cables.

Wherever the steel cable cover enclosed the cables, the wires were fully protected, and in some cases the canvas wrapping, which had been placed on both of the southerly cables, has only been burned off for a distance of 6 or 8 feet from the saddles.

The bolts, sheaves and heavy material in falling through the tower have bruised the lighter angles and lattice bars to a considerable extent, and one of the main girders in the top platform of the tower has its top flange bent about 2 inches out of line. The plate covering of the south portion of the tower has also been buckled to some extent by the heat. It is of course impossible to tell just how much damage has been done to the wires of the A and B cables until they have been tested. Mr. Nichols speaks in the highest terms of the work of Assistant Engineer Kingsley L. Martin in assisting in extinguishing the fire.

Havana, Cuba, has a record for the year ending with September entirely free from yellow fever.

The twenty-fifth anniversary of The Engineers' Club of Philadelphia will be celebrated by a banquet at the Union League, on the evening of Saturday, December 6th.

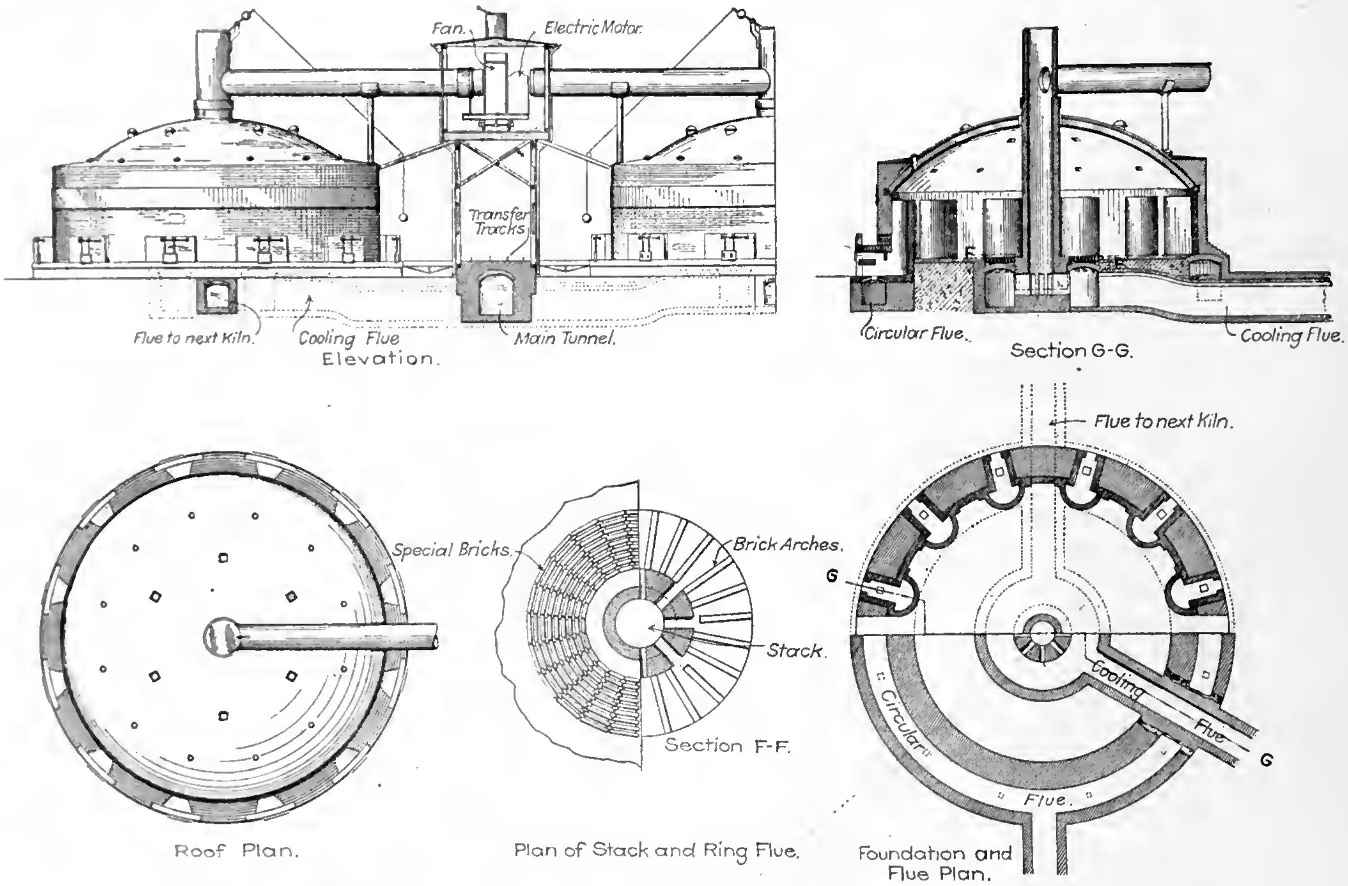
The Removal of Snow and Ice from the streets of Manhattan Borough, New York City, during the coming winter, is causing Commissioner Woodbury of the street cleaning department some anxiety. Proposals have twice been rejected, there being each time only one bidder, who offered to do the work for 39 cents per cubic yard, which is considered to be about four times too much.

The Corner Stone of the $3,000,000 public library building for the City of New York was laid on November 10. Messrs. Carrerre & Hastings are the architects and the Norcross Brothers are the builders of this structure.

The British Pacific Cable was completed on October 30, when the last section between Brisbane, Australia, and Vancouver, B. C., was laid at the Fiji Islands. One section of this cable, between Bamfield Creek, Vancouver Island, and Fanning Island, is the longest in the world. A speed of over 100 words per minute has been attained on this long section with the Deerlove transmitter.

The Pacific Northwest Society of Engineers held its regular meeting in Seattle on November 1, at which Mr. J. M. Clapp, Assistant U. S. Engineer, read a paper entitled "The Improvement of Gray's Harbor, Wash.", describing the preliminary survey work, the construction plant, the method of driving piles for the railroad tracks along the jetty, the process of constructing mattresses for the foundations of the jetty and the method of completing the sea wall.

Distribution of Disinfectants is carried on at Charleston, S. C., during six or eight months of the year, according to the last report of the health officer, Mr. J. M. Green. A solution of copperas is sent through the streets and applied to all places needing deodorizing. Quick lime, chloride of lime, and copperas solution are also given to anyone applying. In all cases of contagious diseases carbolic acid is supplied, and at the termination of the case the premises are fumigated with formaldehyde gas, and articles of clothing, bedding, etc., are carried to the disinfecting cylinder, where they are subjected to a temperature of 230 degrees Fahr.



DETAILS OF A KILN IN THE PAVING BRICK PLANT AT CLEVELAND, O.

A Septic Tank at Bedford, Ind.

The sewerage system recently installed at Bedford, Ind., comprises about 7½ miles of vitrified pipe lines, which will collect the sewage from about half the territory covered by the city limits, and a large septic tank so arranged as to be capable of dealing at almost any desired rate, with whatever quantity of sewage reaches the tank. This result is accomplished by dividing the tank lengthwise into three compartments of different widths, and arranging an inlet trough so that each compartment can be used separately, two together, or all three continuously. This feature is considered of great importance because of the fact that the most effective period of flow through a septic tank varies very considerably according to the quality and amount of dilution of the sewage, and the temperature.

At the inlet end of the septic tank, and covered by the same roof are two detritus tanks, or grit chambers, each 24x7½ feet in size and about 8 feet deep below the flow line. Solid matters are to a large extent deposited in these tanks. The sewage enters each of them through two 10-inch pipes leading from a diversion manhole from which the sewage can be turned into either or both of the chambers, as may be desired. A 2-inch baffle board about 3½ feet deep is placed across the center of each chamber.

On the top of the 24-inch concrete wall which separates these grit chambers from the septic tank proper, is arranged a wooden trough 12 inches wide, with a weir about three feet long and 9 inches above the bottom of the trough, opening from each of the grit chambers. On the other side of this trough are three more weirs, each opening into one compartment of the septic tank. The crests of all of these weirs are about 3 inches below the flow line, so that, except when a new compartment is filling, there is no appreciable disturbance of the surface of the liquid as it passes from the grit chamber to the septic tank. In building this controlling trough, three 4x6-inch wooden blocks were bedded in the concrete wall, one at the center and one at each end, and were anchored to it by two ¾-inch anchor bolts for each block. The trough, which is of 2-inch planking, was then securely nailed to these blocks, after being bedded in cement. All of the five weirs in the inlet trough can be closed when desired by wooden gates made to slide vertically in grooves at the sides. By means of this arrangement, therefore, the sewage can be made to flow from either or both of the grit chambers into the trough, and from there into any of the septic tank compartments. Baffle boards 3½ feet deep are placed close to the trough across both the grit chambers and the tank compartments, so as to insure an even flow of the liquid. Baffle boards are also placed across the center of each tank compartment. A similar trough and weir arrangement at the outlet end of the tank provides for the effluent, a 12-inch outlet pipe leading directly from this outlet trough.

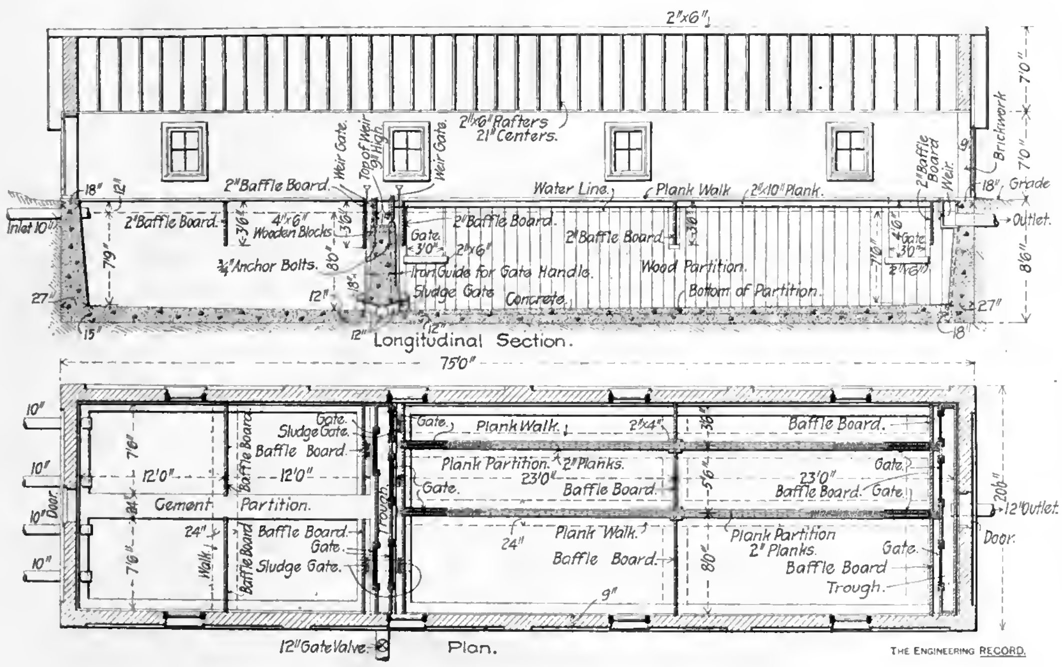
The septic tank is 46x17 feet in largest inside dimensions, and about 7 feet 9 inches deep below the flow line. It is divided by plank partitions into three longitudinal compartments, as shown in the illustrations, and large wooden gates are provided at both ends of each partition, so that the sewage can be passed first through the large compartment, then back through the central one, and then through the smallest one to the outlet or, if so desired, the flow may take place in the opposite direction, beginning with the small compartment, and ending with the large one. If such a long rest period is not desired, any two of the compartments may be used and the third cut out entirely, or it may be still further reduced by making use of only one of the compartments. It is thus seen that a variety of combinations are available, by means of which the proper rest period for any given condition of the sewage may be found by experiment. The widths of the compartments are about 3½, 5½ and 8 feet, respectively, and the capacity of the smallest compartment is about 8,700 gallons, and of the three combined, 42,800 gallons, thus giving a wide range.

As will be seen from the illustrations, the main body of the tank is of concrete, with outside walls 27 inches thick at base and 18 inches thick at the top. At the division wall between the grit chambers and the septic tank proper the thickness of the floor is 12 inches, which thickness is gradually increased to 18 inches at the outlet end and 15 inches at the inlet end. The bottoms of the grit chambers as well as the septic tank thus have a slope toward the main division wall, where, at the lowest level, a sludge gate is provided for each compartment. Whenever considered necessary, any one of these gates can be opened and the accumulated sludge drawn off through a 12-inch drain without interfering in any way with the operation of the rest of the installation.

The concrete used for this work was a 1: 2 : 4 mixture, the broken stone or gravel ranging in size from 1 inch to ⅛ of an inch. The side walls were laid first, with grooves about 4 inches deep left in them at the proper places, in which the plank partitions were afterward bedded. After the roof was put on, the whole inside of the tank was given a coat of plaster consisting of equal parts of Portland cement and sand. The bottom was laid after the side walls were completed, and the wood partitions were put in place before the last 4 inches was laid. The partitions are made of three thicknesses of 2-inch planking placed on end and well nailed together, with a 2x10-inch pine batten along each side at the top, and bolted through the partition every 18 inches with ½-inch carriage bolts. The grooves in which the partition gates slide were made by cutting the inner one of the three thicknesses of planking 3 inches wider and deeper than the outer ones. These gates can be raised or lowered by hand, either directly or by means of levers.

The roof over the septic tank is supported on 9-inch brick walls. An ordinary timber roof framing was employed, with 2x6-inch rafters spaced 21 inches apart, and 2x4-inch cross pieces. One-inch boards and No. 27 galvanized iron were the materials used for the roof covering. A door at each end and four windows on a side were provided. Two-inch pine plank walks were laid along all the main divisions of the tank, for convenience in getting at the numerous gates.

This septic tank was designed and the specifications for it drawn up by Messrs. Alvord & Shields, of Chicago, while the map and profiles for the sewerage system in connection with the tank, were drawn by the city engineer, Mr. G. C. Houston, in consultation with the above-named firm. The specifications for the sewerage system were also prepared by the city engineer with some suggestions from Messrs. Alvord & Shields. Although the matter of filter beds for further purification of the tank effluent has been considered, no definite plans have as yet been prepared, and the septic tank will be operated alone for the present. The information and drawings from which the preceding description has been prepared were furnished by Mr. Houston.



SEPTIC TANK AT BEDFORD, IND.

A Chimney with wash room and store rooms arranged in two stories in the bottom of the structure serves the Trebbinerstrasse power station of the Berlin, Germany, elevated and underground railway. The plant is one in which close utilization of space was necessary, and the boilers being located in a story above the engine room, the smoke flue did not have to begin below them. The stack is some 262 feet high and square in section at the bottom, between 21 and 22 feet on a side.

The Storm-Water Run-Off in the city of Philadelphia is being carefully investigated, according to the latest report of Mr. Wm. C. Haddock, director of the Department of Public Works, with a view of obtaining data for the accurate design of sewers. For several years past the Bureau of Surveys has been installing instruments for the observation of the rise and fall of the flow of water in the sewers, and comparison has been made with the amount of rainfall as indicated by pluviometers installed in the various district offices. In addition, by careful observations with proper instruments, velocities of the flow of water in the sewers at various depths have been tabulated. A careful record of the high and low tides occurring in the Delaware River is also kept.

The Water and Lighting Plant at St. Louis, Mich.

A combined water-works pumping station and electric lighting plant capable of being operated either separately or together, and run by both water and steam power, comprises the interesting installation owned by the city of St. Louis, Mich. The city is located in Gratiot County, and has about 1,200 inhabitants. A moderate size stream called Pine River flows through the city, and water power was developed a number of years ago under a twelve-foot head, which afforded ample power for the city's needs, except during about six to eight weeks in the summer time when steam power had to be resorted to. A moderate rental is paid for this power.

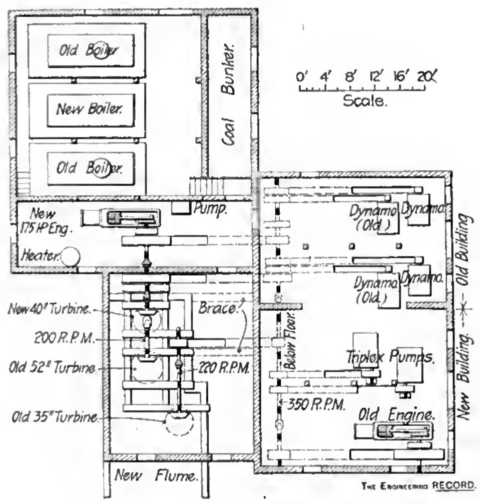
The city installed a small water-works plant in 1879 with approximately four miles of pipe, varying in size from 4 to 8 inches in diameter. No standpipe was used and a 500,000-gallon duplex power pump was installed, operated by a vertical turbine wheel of the old Leffel pattern. About the same time a franchise was granted to private parties for an electrical lighting plant. This plant was installed some distance below the water-works, and consisted of two 150-ampere Thomson-Houston dynamos furnishing current at 110 volts and driven by a 52-inch Leffel special turbine.

There was also installed a relay steam plant consisting of an 80-horse-power tubular boiler and an automatic engine. As the population of the city increased, it was found that the pumping capacity at the water plant was inadequate and an 80-horse-power tubular boiler with a 12x8x12-inch single-cylinder fly-wheel steam pump was added, and the old turbine wheel was exchanged for a 35-inch Sampson wheel. This proved to be only a makeshift, however, and for some years past the city has been without fire protection and has had an inadequate supply for domestic purposes, while the operating expenses were largely increased by the necessity of using steam power continually as well as water power.

The electric lighting plant was purchased by the city in 1900, when it was discovered to be as inadequate for its needs as the water plant. To correct this defect, the city purchased two modern dynamos capable of furnishing 500 amperes each at 110 volts, only to find that the combined power of the engine and water wheel was unable to carry this load satisfactorily, besides running the operating expenses up to a point out of all comparison with the work performed. The coal bill for this plant amounted to over $3,000 per year, and further expense was entailed by the employment of two sets of operating engineers, and the annual rental for the water power. In April, 1901, the old timber dam furnishing the water power was washed out by a flood and Mr. A. T. Maltby, of Chicago, was called in to devise a method of putting both plants into condition to take care of present and future requirements. A new dam of concrete and steel, with a 12-foot fall was constructed at a point about a quarter of a mile farther down the river and about 50 feet above the lighting plant.

The river bed is underlaid with a deep bed of blue clay or marl, very hard and making an excellent foundation. It is covered, in the neighborhood of the dam site, with a layer of gravel about 2 feet thick. Two trenches were excavated across the stream into this hardpan for core walls to prevent any flow under the dam. Foundations of concrete were also provided at the same time for seven steel pipes or columns. These columns were connected together with tie plates 8 feet above tail water and again 3 feet above high water. The wing walls at each end of the dam were made of rubble stone masonry laid in cement, and in the dam proper, concrete was tamped into a form up to the 8-foot tie plates. A steel apron was riveted to these plates, covering the top and downstream face of the dam and a plank apron was built in the bed of the river extending 32 feet downstream. Angle irons were riveted to the sides of the columns for the flash boards to rest against, which at ordinary flow are 4 feet high, making the total fall 12 feet. This arrangement of flash boards was provided in order to take care of the spring floods. The steel columns were filled with concrete, and on top was laid a bridge for foot travel, which also provided a platform from which to handle the flash boards. The dam is 60 feet long between the pier walls, and an earth embankment about 90 feet long was necessary at one side of the head gates.

It was decided to consolidate the water and lighting plants and to abandon the old water plant entirely, except that the turbine wheel and boiler would be used at the new location. The old flume leading to the electric light plant was found to be in a bad state of decay, besides being too small; but the wheel pit was in good condition and large enough to accommodate another 100-horse-power turbine, besides being susceptible of enlargement to accommodate the 35-inch Sampson wheel from the water-works plant. A new flume was therefore constructed.



Power Plant, St. Louis, Mich.

The building containing the dynamos was of brick, two stories high, and was extended in the same design and manner of construction to receive the new pumps. A new brick engine and boiler house 30x40 feet was also constructed for the steam plant, and a wheel house of wood covered with steel in imitation of brick. In the original plant a countershaft was located below the floor of the dynamo room and the engine and turbine wheel were connected by belts. This countershaft was extended under the floor of the new pump room with a clutch coupling. The 35-inch, 75-horse-power Sampson turbine from the old water plant was installed in the new flume and connected by a belt to this new countershaft. The old engine previously used in the lighting plant was placed in the pump room and also belted to this countershaft, which at full speed ran the same as the part which drove the dynamo.

Two 7x8-inch double-acting, triplex power pumps of 750,000 gallons capacity each were purchased and installed in the pump room, and driven by belt power from the countershaft, the object being to operate the pumps either by steam or water power from the countershaft.

The old steam boiler was brought over from the abandoned water station and placed alongside the one already in use and a new one of the same size and capacity purchased, making a battery of three boilers in the new plant. A 175-horse-power four-valve simple engine of the Russell make was installed in place of the old engine, together with a Stilwell open heater and purifier and a 6x4x6-inch boiler-feed pump. The old 52-inch Leffel turbine was left in place and a modern 40-inch Sampson wheel added to drive the lighting plant. It will be perceived that the water and lighting plants can be operated separately or together as circumstances may require, by the manipulation of the clutch coupling in the countershaft. The power of the large engine or turbines can be transmitted to the pumps or the power from the small turbine or engine in the pump room can be transmitted to the dynamos, or all can be combined.

As the pumping plant is operating under the direct pressure system, with no standpipe, the speed will vary in accordance with the amount of water consumed, and consequently when the engine is in operation it will have to be controlled by the throttle, and in order to gain as much economy as practicable, the governor was set to cut off at not later than ¼-stroke. This arrangement was found to work very satisfactorily, requiring very little attendance. To the practical engineer the saving in steam by using the cut-off engine is apparent, the consumption being 35 pounds against 60 to 150 in the small direct-acting steam pumps. The synchronous action of the triplex pump makes it perfectly practicable for a belt drive, and no trouble whatever is expected from this source. A 6-inch relief valve was placed in the main near the pumps to guard against excessive pressure.

A Sewer Enlargement in Grand Rapids, Mich., is described as follows in the last report of L. W. Anderson, city engineer: The enlargement consisted in removing the upper portions of the old brick oval sewer to within 6 or 10 inches of the bottom, leaving sufficient to carry the ordinary flow. Outside of the old bottom, concrete footing and side walls were constructed, and after plastering the bottom, a 6-inch concrete arch was built in place.

The Chamber of Commerce of the State of New York dedicated its new house on Liberty Street, New York City, on November 11. Many distinguished men attended the ceremonies, among them President Roosevelt, who summed up the genius of the organization when he said, in the course of his address: "I greet you in the name of the people, not merely because you stand for commercial success, but because this body has been able to show that the greatest commercial success can square with the immutable and eternal laws of decent and right living and of fair dealing between man and man." The Chamber of Commerce was organized in 1768, but now for the first time occupies a building of its own.

The Smoke Nuisance is receiving the attention of the city authorities of Providence, R. I., who are endeavoring to obtain necessary legislation for its abatement. Three large industrial concerns have voluntarily encouraged this movement by offering to install apparatus in their power stations which would prevent black smoke. With this purpose the Rhode Island & Suburban Railway has contracted for an equipment of Roney mechanical stokers for its new boiler plant of an ultimate boiler capacity of 8,300 horse-power. The Narragansett Electric Lighting Company is installing a complete equipment of Roney quadruplex stokers, under Babcock & Wilcox boilers of 4,500 horse-power capacity. In the plant of the Brown & Sharpe Manufacturing Company, similar stokers have been in use for some time under two batteries of Babcock & Wilcox boilers, with excellent results.

The Mechanical Plant of the Ansonia Apartment Hotel, New York City.

One of the latest apartment hotels in New York City and probably the largest and most complete in this country is the Ansonia, a seventeen-story structure fronting on Broadway from 73rd to 74th Streets, and occupying about 37,000 square feet of ground area. Like the larger part of the buildings of this class that have been erected in New York (some 90, it is stated, in the last two years), it has its own mechanical plant, which is of interest apart from its size, on account of a number of unusual features. Among these are the installation of direct-acting plunger hydraulic elevators of high lift, elaborate provisions for condensing as much exhaust steam as possible, the utilization of the heat of the flue gases for feed-water heating and a very extensive system of ventilation.

The Ansonia Apartment Hotel, New York.

The ground floor of the building will be occupied by a bank and several high-class stores, a large restaurant, a grill room, a ball room, and a reception room, together with the necessary offices in connection with the hotel proper. Of these the manager's office is of greatest importance, due to its appurtenances. Below the first floor there is a basement containing an up-to-date kitchen and laundry with a large amount of storage space for the use of the tenants, and below the basement is the cellar containing the power plant, a large swimming tank with accessory baths and lockers, and a storage room for automobiles.

With the exception of the second, sixteenth and seventeenth floors the upper stories are practically identical, each being divided by the H-shaped form of the corridors into five groups of apartments, as shown on the typical floor plan here given. By the ingenious arrangement of this floor plan, different combinations may be made to give suites of various sizes from one to fourteen rooms. The larger suites have kitchens (the cooking being done with gas ranges or electric stoves), dining rooms, parlors, bed rooms, servants' rooms and baths; many of the two-room combinations also have bath rooms. There are a number of single rooms easily isolated from a large suite if but one room is wanted.

Dining accommodations for tenants who do not wish to have cooking done in their apartments are supplied on the sixteenth floor in a large, richly decorated dining room extending up through the seventeenth story; in this room 250 persons can be served at once. A small kitchen adjoins, and when its facilities are not adequate, the larger kitchen in the basement is called upon, intercourse between the two being accomplished by three electric dumb waiters. The second story is modified from the regular arrangement by replacing the section around the Broadway court with private dining rooms. The two tower corners of the seventeenth floor on Broadway are to be used for studios, and the remainder of that story, where not cut out for the high-ceiled dining room on the floor below, is divided off for servants' quarters. In general the apartments are heated by steam, but in addition most of the rooms have open fire places with gas logs.

The power plant, shown in the accompanying plan, is in the cellar under the rear of the southern half of the building, that is, along 73rd Street. The coal is delivered at the rear of the building and dumped, through manholes in the court, to the storage space below. The capacity of the coal storage is 340 tons. The boilers are near and facing this space and the coal is carried by cars on tracks and dumped in front of the furnaces. The firing is done by hand and the ashes are removed in wagons which are lowered into the fire room by a wagon lift. This lift is also used to lower automobiles to their storage room. The boiler equipment consists of four Caldwell water-tube boilers with McClave shaking and dumping grates, and are arranged in two batteries. Each battery contains one boiler of 428 and one of 301 horse-power. The tubes are 4 inches in diameter and 16 feet long. The total heating surface is 13,136 square feet and the total grate surface is 297.5 square feet, making the ratio of heating to grate surface 47 to 1. The boilers and grates were installed by Messrs. James Beggs & Co., of New York City. The chimney is a steel plate stack 240 feet high erected inside a brick casing, which also serves as a ventilating flue and a shaft for the exhaust steam pipe to the roof.

The steam, at 125 pounds pressure, passes from each boiler through a valve into the middle of a horizontal connection of U-form; one leg of this enters a 12-inch main and the other a 7-inch auxiliary main, each leg having a valve at its end. The 7-inch main passes backward around one end of the boiler room toward the engine room and supplies several pumps on its way, finally entering one end of the engine header which is also fed at the middle by the 12-inch main run around the other end of the boiler room. In the event of an accident to either main the other may temporarily carry the whole supply. The 12-inch main contains a Foster automatic stop valve which closes if the pressure on the boiler side falls below that on the other side, and opens again when they are equal. The 12-inch header from which the engines are supplied also feeds the elevator pumps, and, continuing east, enters the refrigerating room to supply the ammonia and brine circulating pumps and the cold drinking-water pumps. All steam pipes are dripped through traps, the ends of the mains having drop legs with blank flanges pierced by the drain pipes. A separator is installed in both the 7-inch and the 12-inch mains where they connect with the 12-inch engine-room header. The pipes are covered with Keasbey & Mattison 85 per cent. magnesia sectional lagging. The plant as originally designed was to include a Morse garbage and rubbish destructor, the gases of combustion of which were to be utilized in a Foster steam superheater. This has not been installed as yet, although shown in position on the plan of the power plant. The engines are of the American Ball compound duplex type with the low-pressure cylinder above the high and in the same casting. They are direct-connected to Westinghouse multipolar generators. Three engines of 440 horse-power are coupled to 250-kilowatt machines, and two of 220 horse-power to 125-kilowatt machines. The larger engines have cylinders 19 and 32x18 inches and run at 200 revolutions per minute, and the smaller ones are 13 and 21x16 inches, running at 225 revolutions per minute.

The exhaust from the engines enters a main located in a trench under the floor; which discharges, with all pump exhausts, into a 16-inch main above the floor containing a Webster grease extractor. Beyond the extractor this main branches, one part going to the house-heating system, the second to the hot-water drum for the hot-water system of the building and to the feed-water heater, and the third to the outboard exhaust riser in the chimney casing, the usual back-pressure valve being provided in this pipe in the sub-basement. The riser is of 16-inch spiral riveted pipe and branches at the roof to a special air-cooled condenser on one side and through a relief valve on the other, this valve being arranged to open nine stacks of 1¼-inch pipe, each stack being 6 feet wide by 7 feet 4 inches high and having a thermostatic valve on its return, the Webster system of vacuum heating having been applied to the heating system. These stacks are in a housing of No. 22 galvanized iron supported by a frame of 2-inch angle irons, through which a current of air, drawn from the vent shafts from the kitchen and power plant, is forced. While the air is warm, it is assumed that it will be at least 120 degrees cooler than the steam to be condensed. The exhaust head is the open condenser type, described in The Engineering Record of July 22, 1899. The exhaust, in order to reach the outside air, has to pass through some 160 sheet-iron tubes 2 inches in diameter and air and water. Exhaust steam is utilized as stated, but when insufficient in amount, live steam can be supplied through a pressure reducing valve. The radiators are of the direct type and of cast-iron, with two or three exceptions where coils of common pipe are used. In most cases the radiators are located in window recesses, the brick side being covered with furring, and are boxed in with asbestos lined wooden covers containing registers over the top. The registers are sometimes in the center, but more often near one end of the cover, so that the remainder may be used for a window seat. The air inlets opening from the rooms are on the front near the floor. Where enclosed the radiators are of the flue type.

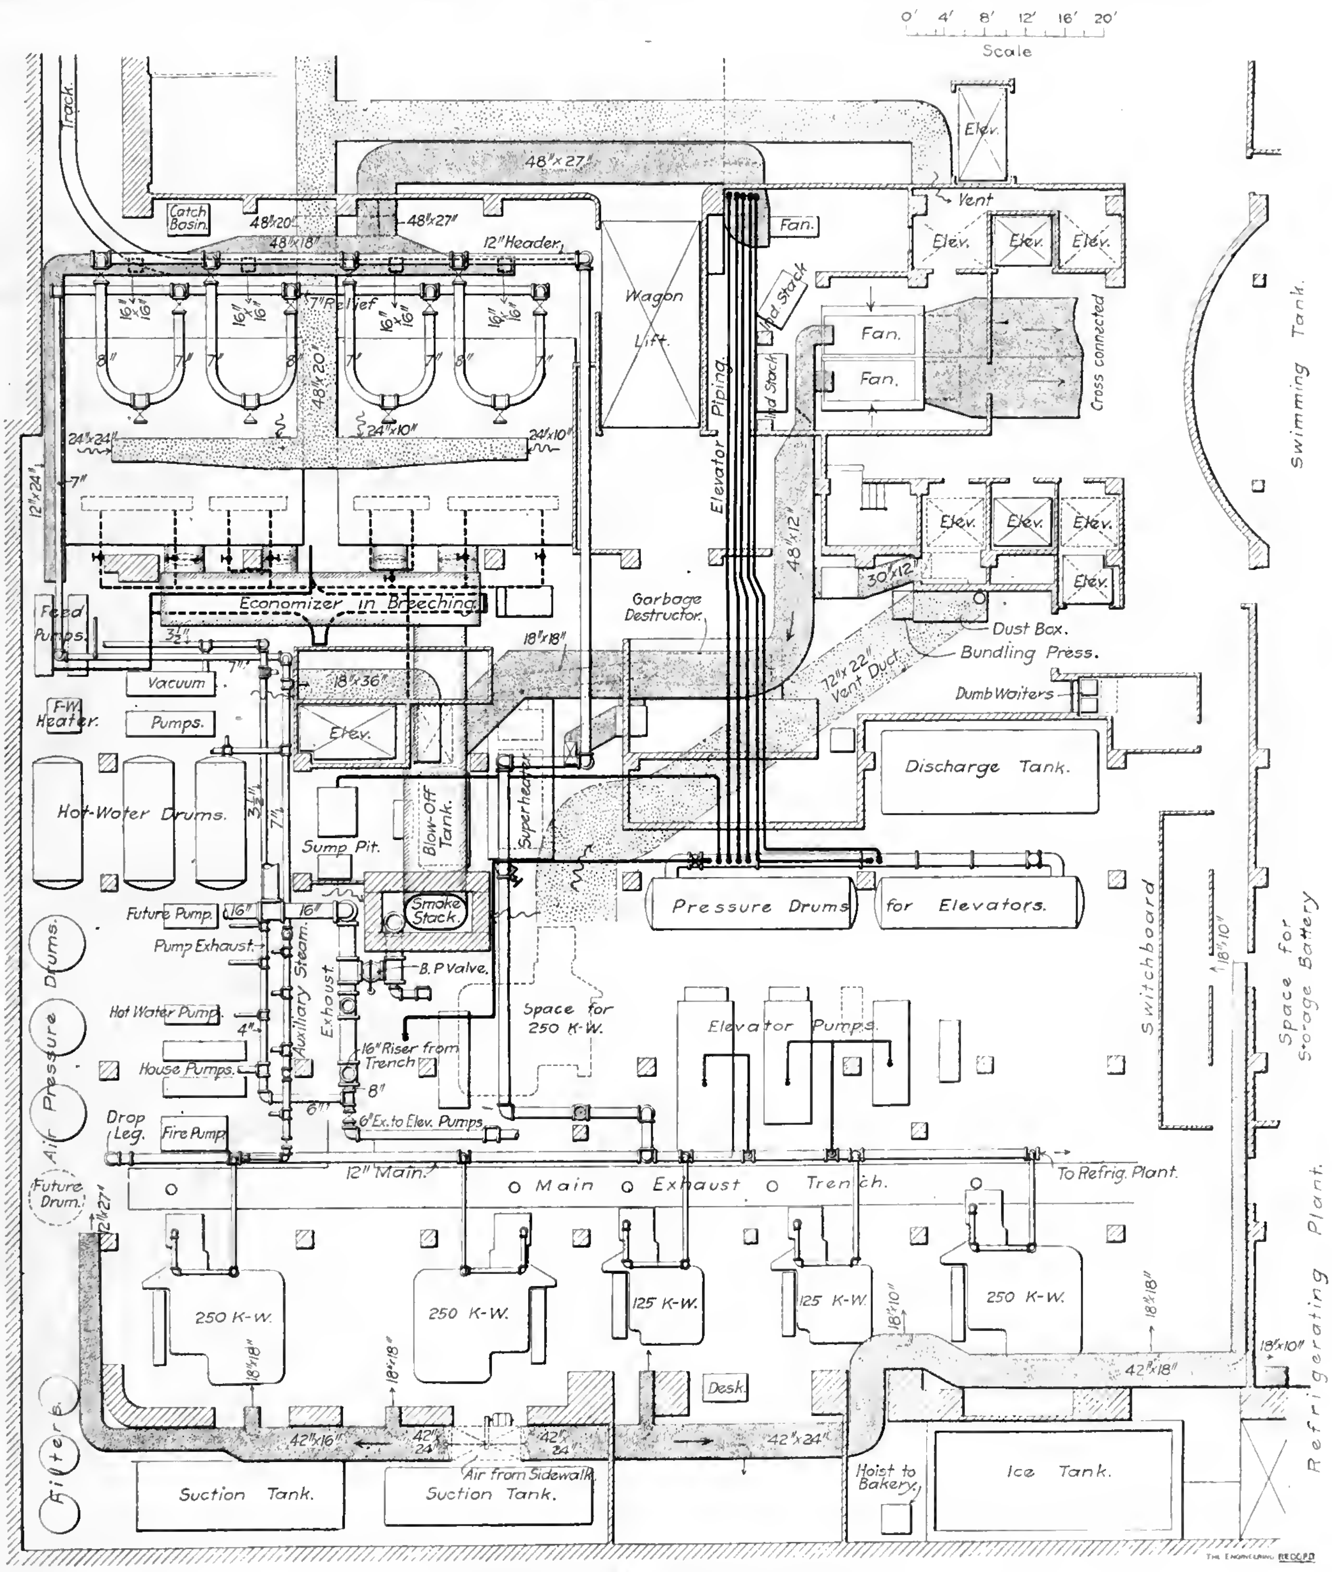
Adjoining apartments are distinguished by two kinds of shading.

only when the heating system and condenser do not absorb all of the exhaust. Steam passing through the relief valve reaches the atmosphere through a special exhaust head. The condenser and exhaust head were designed by the consulting engineer, Mr. Reginald Pelham Bolton. The former is the same in construction as a pipe coil heater but is designed to effect the condensation of steam within it and not the warming of the air outside it. It consists of is more or less condensed by the exposure of the tubes to the outdoor air. The condensed steam is caught in a pan and is returned with the water from the condenser to the return tank in the basement.

The Webster vacuum system of steam heating is employed, as stated, each radiator having the customary thermostatic valve on the return connection which closes when in contact with steam, but opens when surrounded with cold

The suction on the returns of the heating system is usually about 7 inches of vacuum. All returns are collected with the drips previously mentioned in two 6-inch mains which unite at the vacuum pumps. A dirt pot is installed in each of these branches near their union to remove any sediment liable to collect. The cleansed returns are delivered by the pumps to a receiver or drum from which the boiler feed is taken. If the returns become greater in amount than the pumps can handle, the surplus is removed through an overflow; or should the pumps stop, the relief valves placed on the returns will discharge the condensation to a sump pit which is excavated well below the level of all machinery and sewer pipes. The contents of the pit is discharged into the sewer by an automatic bilge ejector or by a 5-inch submerged vertical centrifugal pump.

The vacuum pumps, two in number, are of Knowles make, 10x16x16 inches in size, with drips, such as those from the live steam mains and the exhaust mains beyond the grease extractor, are delivered direct to the heater. The returns from the heating system are received by gravity through a 3-inch pipe from the bottom of the overhead receiving tank, the pipe extending down to the cellar floor and then rising to the top of the heater. This loop seal, constantly filled with water, prevents any air in the tank from entering the heater instead of passing out through the vent to the atmosphere, which all extra feed water required, in addition to the condensation from the heating system, is passed on its way to the heater. A 1-inch spray of cold water condenses the vapors contained in the tank. The tank has a 4-inch blow-off connection and a syphon overflow, both of which discharge into the sump pit. On the outside the tank is provided with a glass water level gauge and a pressure gauge. When desired the tank may be discharged directly to the sewer by a 6x4x6-inch duplex pump.



PLAN OF THE MECHANICAL PLANT.
Reginald Pelham Bolton, Mechanical and Electrical Engineer.

the steam supply under automatic control of a diaphragm valve, which is in connection with the return mains to maintain the desired vacuum. The return tank which receives the air and water from the vacuum pumps, is located in the basement story above. The tank is 36 inches in diameter and is 6 feet long and made of ¼-inch open-hearth steel with dished head of 5/16-inch plate.

The feed-water heater is a Webster Star open heater of 1,000 horse-power capacity. All clean as might happen with a straight connection. The exhaust steam inlet to the heater is 10 inches in diameter and the feed outlet 5 inches. The cold water inlet at the top of the heater is 3 inches in diameter.

The drip drum for foul drips and blow-offs is 4½ feet in diameter and 10 feet long, of ⅜-inch steel with ½-inch heads, and was tested at 175 pounds pressure. Within it is a condensing coil of 2½-inch galvanized-iron pipe, 7 feet long with galvanized-iron headers through

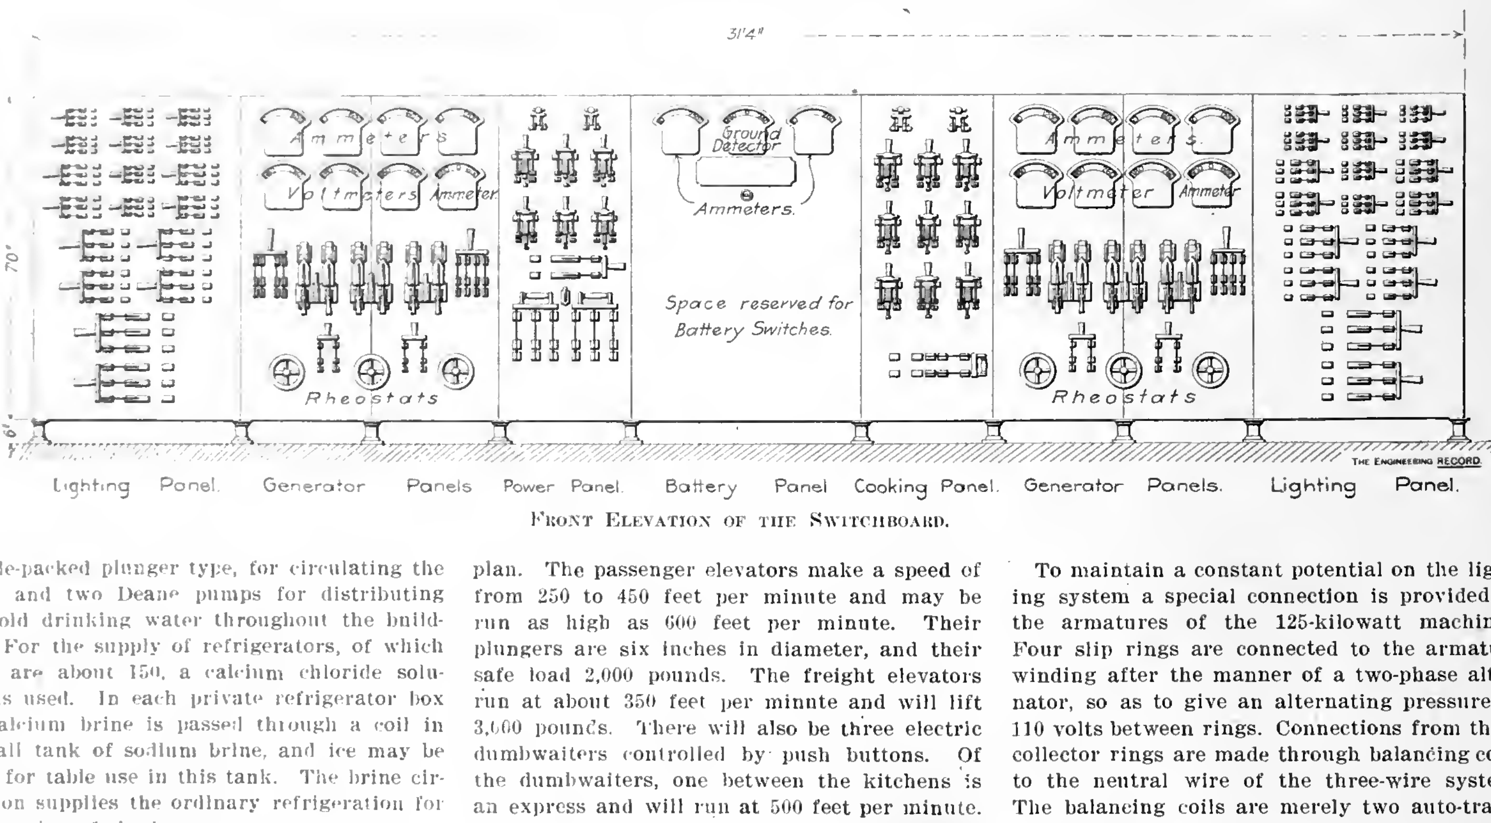
The feed water is drawn from the heater and pumped through a flue economizer to the boilers. The pumps are two of the M. T. Davidson Company's compound type with cylindrical steam-actuated valves. The steam cylinders are 7 and 12x12 inches and the water cylinders 7x12 inches. The steam supply is regulated by a float governor on the heater. The discharge of the pumps is carried in a 6-inch pipe to the smoke connection of the boilers. The economizer is contained in the upper part of the smoke passage and is merely a loop of 6-inch extra heavy pipe passing the length of the breeching to an external header and back again from the header to the center, where it passes out with a sweeping bend to the feed main between the batteries. On the header there is a safety relief valve piped to the feed heater and a blow-off connection. The longer length of the 6-inch pipe is in two pieces, the middle ends being joined in a U-shaped loop by a flange union and projecting through the flue casing. This allows for support, expansion, and repairing. When desired the feed may be by-passed around the economizer directly to the boilers, or the boilers may be fed directly by two 3-inch Metropolitan injectors.

The refrigerating plant is in the sub-basement and was installed by Messrs. Steele & Condict, of Jersey City, N. J. It operates on the ammonia absorption system and has a capacity of 70 tons of refrigeration in 24 hours. In the ordinary day's run probably not more than 5 tons of ice will be made. The rest of the plant's capacity will be used for cooling drinking water and for the tenants' private refrigerators and the kitchen refrigerators. The equipment comprises an absorber, duplicate retorts or generators, a heater or exchanger, duplicate condenser tanks, a cooling tank for ice water, a large brine tank, and an ice-making tank. The pumps are two Knowles pumps for circulating the ammonia, two Knowles compound pumps, 12 and 18½x8½x18 inches of the rated capacity of 1,300 gallons per minute. A reserve pump, 14 and 22x12x18 inches, of the same capacity but of compound type, may be used when the load is excessive. The night service is provided for by a compound pump 12 and 17x10x15 inches, rated at 700-gallons capacity. All of these pumps deliver water at 140 pounds pressure to two pressure tanks, each consisting of two drums, one above the other, 5 feet in diameter and 20 feet long connected by 16-inch pipes. An air cushion is kept on the surface of the water in these drums by a Westinghouse locomotive type air compressor. In ascending, the elevator plungers receive water from these drums and in descending discharge it into a surge tank 8x8½x22 feet, from which the water is again pumped into the drums. The freight elevators are fitted with extra heavy pipe and are operated at 400 pounds pressure, for excessive loads such as safes, by a small heavy-duty Worthington pump, 9 and 3½x10 inches. The wagon lift is 20 feet by 12 feet and has three plungers, one in the center 8 inches in diameter, and one half way between the center and either end 5 inches in diameter.

The complete elevator service embodies six passenger elevators, arranged three on either side of the main corridor and about the center of the building, two waiters' elevators, two freight elevators and one wagon lift. There are also seven private service elevators extending up through the tiers of apartments. The location of all elevators may be seen on the typical floor

will probably be installed at some future time. The adjoining panels are for the power and cooking circuits. These are flanked by two generator panels and the two outside panels control the lighting system. At right angles to the ends of the board are two panels containing fuses in the distributing circuits of the lighting system and behind the center of the board two other panels have been placed for the meters of the Edison Company; one to be used for those on the lighting current and one for those on the power and cooking current. On the back of the main board there are two sets of buses. The three bars constituting the upper set are for the positive, negative and neutral leads from the street service and the five bars of the lower set are the positive, positive equalizer, neutral, negative equalizer and negative buses of the house plant.

The generators are all compound wound and have their series fields in two parts equally divided in both leads. This was necessary for the smaller machines, because the lighting load is on the three-wire system, and, when one side is carrying a greater load than the other, the field excitation must be correspondingly increased. Obviously, if the entire series field was in the other lead no extra excitation would be provided. The larger generators were similarly wound because all machines are connected to the same set of bars on the switchboard. This dividing of the series fields made two equalizer bars necessary.



FRONT ELEVATION OF THE SWITCHBOARD.

outside-packed plunger type, for circulating the brine, and two Deane pumps for distributing the cold drinking water throughout the building. For the supply of refrigerators, of which there are about 150, a calcium chloride solution is used. In each private refrigerator box the calcium brine is passed through a coil in a small tank of sodium brine, and ice may be made for table use in this tank. The brine circulation supplies the ordinary refrigeration for the interior of the box.

The hydraulic elevator equipment is of the direct-acting plunger type, which is notable on account of the high lift required. The elevators were installed by the Plunger Elevator Co., of Worcester, Mass. It was, of course, necessary to bore a well beneath the shaft to a depth equal to the height to which it is required to run the elevator, in this case from 200 to 230 feet. The drilling was done by a Davis-Rand Australian drill and solid pieces of the core were taken out 12 inches in diameter and sometimes as long as 12 feet.

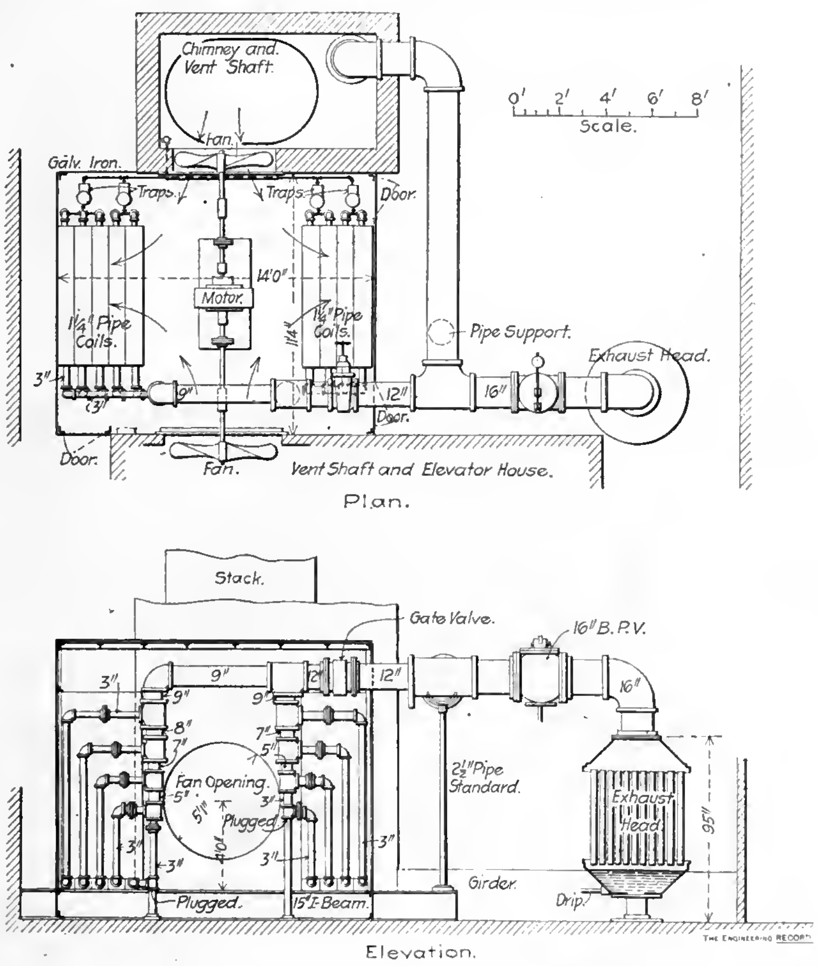
For the passenger elevator service three Worthington pumps are used. For the ordinary demands a duplex, triple-expansion pump is used, with steam cylinders 13, 18 and 29 inches in diameter and a water cylinder 14 inches in diameter, with an 18-inch stroke, and having a plan. The passenger elevators make a speed of from 250 to 450 feet per minute and may be run as high as 600 feet per minute. Their plungers are six inches in diameter, and their safe load 2,000 pounds. The freight elevators run at about 350 feet per minute and will lift 3,000 pounds. There will also be three electric dumbwaiters controlled by push buttons. Of the dumbwaiters, one between the kitchens is an express and will run at 500 feet per minute. The others pass through the serving rooms on each floor.

The electric power and lighting system is independently capable of supplying all of the needs of the building, but connections to the street mains of the New York Edison Company have been provided, so that a crippling of their plant may not cause any inconvenience to the tenants. The motors for dumbwaiters and fans are supplied from a two-wire circuit and the lighting load is on a three-wire system with particular features for maintaining constant voltage.

The switchboard, of pink Tennessee marble, is 7 feet high and 31 feet 4 inches long, and contains seven panels. The arrangement of the board and its parts is shown by the accompanying elevation. The middle panel is reserved for the connections to a storage battery which

To maintain a constant potential on the lighting system a special connection is provided in the armatures of the 125-kilowatt machines. Four slip rings are connected to the armature winding after the manner of a two-phase alternator, so as to give an alternating pressure of 110 volts between rings. Connections from these collector rings are made through balancing coils to the neutral wire of the three-wire system. The balancing coils are merely two auto-transformers, one in each phase, with their middle points connected together and to the neutral wire. Their purpose is to equalize the current in the several sections of the armature when the load on one side of the system exceeds that on the other and thus prevent the voltage in the overloaded side from dropping.

The plans provide for the installation at some future time of a storage battery auxiliary of about 134 cells placed in parallel with the generators with their middle point connected to the neutral wire. By its use the generators will be assisted in carrying the peak of the load, and during the lightload hours the battery can be charged through a motor-driven booster to be provided for that purpose. The battery is to have a normal rate of discharge of 420 amperes at 240 volts for four hours and furnishing as high as 3,000 amperes, if necessary. At



Air-Cooled Condenser and Exhaust Head.

present the battery panel contains two ammeters which will be inserted in the two legs of the battery to show their individual currents at all times, and a double-throw voltmeter for a ground detector to measure the leakage in either side of the system.

The power and cooking panels each have circuit-breakers on their distributing feeders and a double-throw, two-pole switch for connecting to the generators or the street mains. On the lower part of the power panel are two three-pole switches for connecting the street service to their buses.

The generator panels are alike, each providing for two 250-kilowatt machines and one 125-kilowatt machine. The present plant has but three of the larger generators, but space has been reserved for another large unit in case it is required. Each small machine is connected to the bus bars through a four-pole, single-throw switch on the left of the panel; the positive and negative leads also pass through a two-pole circuit-breaker with a magnet on each leg so that an overload on either side of the system will open the circuit. The other four-pole switch controls the balancing coil connections to the armature. The two circuit-breakers on either side of the one just mentioned are for the two larger machines and have magnets on but one leg, the negative; the other leg connects to the negative equalizer. The positive and positive equalizer leads connect to the two-pole switches at the bottom of the panel and are protected by a single-pole circuit breaker at the generator in the positive brush lead.

At the top of the generator panels are the meters. The two outside ammeters on the upper row have a capacity of 1,200 amperes and indicate the current supplied by each of the 250-kilowatt generators on that panel. The middle two meters with a 600-ampere capacity show the current the small generator supplies to each side of the three-wire system. The remaining ammeter has the same capacity but is double-throw and shows at a glance which side is receiving the most current and what the excess amounts to. The three voltmeters and the three rheostats at the bottom are for the three machines.

The lighting panels have double-throw switches on all of their distributing circuits so that any or all may be connected either to the street system or to the house plant. The total number of lights in the building will be about 18,000. The wiring of each apartment is controlled from panel boxes containing switches to the various rooms. The cooking current is on an independent feeder. Throughout the building all risers are boxed in and all horizontal runs are made in the space between the ceiling and the floor above. A pull box is provided in the conduits for every four quarter bends.

The ventilating apparatus is quite elaborate and complicated, combining plenum and exhaust systems. The principal fresh air inlet is through a centrally located shaft, about 8 feet square in cross-section and rising beside one group of passenger elevators. The fans are in the cellar and draw the air from the base of the shaft through cheese cloth screens and tempering coils, which will warm the air to about 70 degrees. The coils are arranged in two sections having in all 8 stacks of 1¼-inch pipe, giving a total of about 4,600 square feet of heating surface. The usual temperature regulation is provided by a cold air by-pass.

The air circulation is established by two 140-inch New York blowers set side by side and belted to two 20-horse-power C & C motors. At their normal speed of 230 revolutions per minute each blower has a rated capacity of 47,000 cubic feet and may be run as high as 300 revolutions, when desired. In addition to their regular discharges there are two smaller openings 12x24 inches, one in the casing of each blower, which combine to supply ventilation to the large dining room on the sixteenth floor. The discharge ducts from the fans can be tied together, so that either one can supply the whole building, if necessary. They deliver through horizontal ducts along the ceiling of the cellar which decrease as risers through the building are taken from them. At their largest point, near the blowers, these ducts are 72x36 inches in area. At the base of each riser the air is further warmed by extended surface radiators which are supplied, as are the main tempering coils, from the heating system, using exhaust steam, and returning their condensation through thermostatic valves to the return system. This method of subdividing the heating of the air possesses several advantages, in that the ducts can be smaller for the same quantity of air passed than if heated entirely at the fans, in that less heat is given up to the basement, and in that independent control and regulation of the heat for different sections is afforded. These supplementary heaters are located at the base of various flues, distributed about the building and the air is delivered in each apartment through a register just inside the entrance door.

For removing the vitiated air from the five tiers of apartments into which the building is divided, as described, there are five vent fans on the roof. These are connected at the fifteenth and seventeenth floors by crossngs from widely distributed vent flues. These fans are 48-inch Seymour exhaust fans and are direct-connected to 5-horse-power C & C motors. Every tier of toilet rooms and every tier of kitchens has a vent shaft with branches at each floor. The kitchen vent openings are under the hood of the gas ranges. The gas log fire places, about 300 in number, also serve as vents and are connected to the same five fans. Instead of using chimneys for each of these, a single terra-cotta drain pipe is run vertically for each line with a branch to each fireplace having a damper placed beyond the control of the tenant. At the fifteenth floor these flues are connected into the various systems by black-iron ducts, 18 inches wide and 8 inches deep, and on account of the high temperature of the gases, are covered with 1 inch of air-cell asbestos. These are laid on furring over the finished ceiling. The vent ducts crossings are 10 inches deep, of widths varying from 16 to 26 inches, and are of galvanized iron. All toilet vents project well into the center of their flues to obviate any danger of their contents backing up into living rooms.

All ventilation thus far discussed applies only to the floors above the first. The cellar and basement are ventilated with untempered air. The power plant receives fresh air from two sources. One system at the 73rd Street side takes air from the sidewalk and distributes it in opposite directions through two ducts. There are two fans at the air inlet, one for each duct. They are of the disk type, 42 inches in diameter and mounted on the same shaft which is belt-driven by a 6 horse-power C & C motor. This system has seven outlets in the engine room and three in the ice plant. The second system supplies air to the boiler room through a duct with five outlets, and to the basement above through two risers. The blower for this system will be located in the space near the large main fresh air shaft from which it will take air unheated. This fan will be a 100-inch New York blower, rated at 12,000 cubic feet per minute capacity, but not expected to be called upon for more than 70 per cent. of that amount or about 8,400 cubic feet.

The exhaust air from the boiler room will be taken through a duct having a header with four inlets over the boilers. This duct will connect with a vent from the north section of the cellar and the basement and first floor and will discharge into the north elevator shafts to the exhaust fan on the roof. The engine room is vented through openings in the base of the chimney, the space between casing and steel stack serving as the flue. Close by is an inlet into the base of another flue primarily intended for the basement kitchen ventilation.

To remove the odors of cooking from the kitchen in the basement and keep them from the floors above a rather extended system of ventilation will be employed. Taking it for granted that ample heating will be provided by the cooking ranges, the air is admitted cold from the sidewalk. A pair of 42-inch motor-driven fans distributes the air through large many-branched ducts to all parts. The exhaust ducts are even larger and more widely distributed and will discharge into the vent shaft previously referred to, which rises to the roof. The air from this flue and from the chimney casing is that air which is used for cooling the exhaust steam condenser on the roof. Between the steam coils and in the same housing, there is a 12-horse-power Lundell motor protected by a galvanized iron shield from the heat and direct-connected at each end to a Seymour fan 54 inches in diameter. The latter, through openings on two opposite sides of the housing, will draw the air from the two vents and discharge it against the steam coils and out of the other two sides of the chamber.

The first floor receives its fresh air from the large main systems already described, but is vented on a system of its own. The foul air is drawn down to a system of vent ducts on the cellar ceiling, divided north and south, and connecting to the bases of vent shafts at the rear of the main elevators in which the counterweights run. These are exhausted by two New York steel plate blowers each driven by belts from 12-horse-power C & C motors. Each equipment is housed and the discharges are through screens in the side. The south exhaust fan has a wheel 5 feet in diameter, runs at 250 revolutions per minute and can discharge 10,000 cubic feet of air per minute, and the north fan has a 6-foot wheel with a capacity of 14,000 cubic feet per minute at 230 revolutions.

Having now reviewed the mechanical plant of the Ansonia, it will be interesting to note how, at all times, its performance is indicated to the manager, and how, from his office, he can control it. In this office there is to be a cabinet of black carved oak containing a panel for gauges which show all working pressures on the different services, including the high-pressure live steam, low-pressure steam and vacuum for house heating, these being also provided with recording gauges, and the pressures of the upper and lower water supply systems, ice water system, city pressure and brine pressure. The board also contains thermometers giving the temperatures of the interior of the air supply and voltmeters on the electric system. All of these enable the management to keep a check on the engineering staff and to deal promptly with complaints.

Communication to the engine room, servants' quarters and all apartments is afforded by bell signals and telephones. A central board of 362 stations is located here, connecting all apartments and the public service. The privilege of telephone service is free to all tenants. The Miles Company's system of pneumatic tubes is installed between this point and all serving rooms on each floor, and the main kitchens and stewards' offices. Fire alarm signals are provided at four places on each floor, which ring in this office. If an alarm is received which demands it, the manager may warn the whole of the house at once, or any separate part, by bells throughout the building, provided for such an emergency.

The building was erected and is owned by Mr. W. E. D. Stokes and was planned under his supervision by Mr. Paul Duboy, of New York City. The consulting engineer for the mechanical and electrical work was Mr. Reginald Pelham Bolton. The steel and iron work was done by Messrs. J. B. & J. M. Cornell, and the masonry by Messrs. T. J. Riley and T. J. Brady. The electrical wiring, including the switchboard, was installed by Mr. Frederick Pearce, of New York. The steam fitting was done by Francis Bros. & Jellett, Inc., of New York, and the galvanized iron work by Messrs. Herrmann & Grace, of Brooklyn.

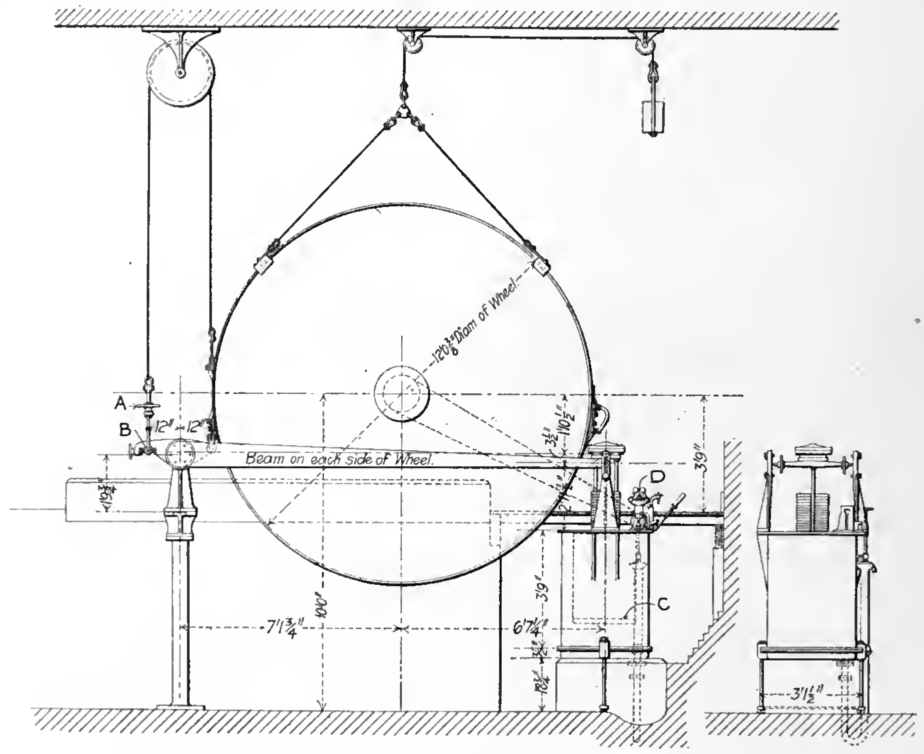
The water supply systems of the Ansonia building were described in The Engineering Record of November first.

Steam Engine Testing Apparatus in the Manchester Municipal School of Technology.

The city of Manchester, England, has recently opened a new and unusually well equipped municipal technical school. It occupies a main building of 7,300 square feet area, exclusive of a textile annex, which covers additional ground space of 1,248 square feet. The basement of the building is a large workshop and laboratory, devoted to mechanical, electrical, steam and hydraulic engineering, and to spinning and weaving. Throughout the building there are chemical, physical and metallurgical laboratories, and numerous workshops and lecture rooms. Besides a preparatory course and a course in pure and applied mathematics, there are departments of mechanical engineering, electrical engineering, sanitary engineering, theoretical and applied chemistry, textile industries and photographic and printing crafts. In the equipment of the steam engineering laboratory, which is under the direction of Professor J. T. Nicolson, head of the department, an extraordinary effort seems to have been made to obtain apparatus which would allow of elaborate and valuable investigations along lines of importance in the field of mechanical engineering; and this is particularly so in the design of the experimental steam engine. From an extended article on the school, in a recent issue of London "Engineering," the following description of the engine and the apparatus for testing it is taken:

The engine is of the horizontal compound condensing type and is capable of developing 350 brake horse-power. The cylinders are 11½ and 20 inches in diameter by 36 inches stroke. It was constructed by Messrs. James Carmichael & Company, of Dundee. There are two interchangeable cylinders of each size, which may be fitted alternately for purposes of experimental work. One of the 20-inch cylinders has slide valves with Meyer expansion plates, while the other has Corliss valves and gear. Of the smaller cylinders, one has been supplied with Sulzer drop valves, and the other with Corliss valves and gear. It is therefore possible to compare the effect of size of cylinder as well as of type of valve. Pressure up to 250 pounds to the square inch can be used and the engine will work to 110 revolutions per minute.

Each end of each cylinder has separate exhaust pipes, so that the amount of steam taken by these respectively can be found by measurement after condensation, separate condensers being provided for the purpose. The ends, sides and pistons of the cylinders are steam jacketed. The steam when supplied to any of the cylinders, may either go directly into the steam chests, or be passed through the jackets before entering them. In the latter case it may, or may not, pass through a steam separator.



ABSORPTION BRAKE FOR A 350-HORSE-POWER EXPERIMENTAL ENGINE.

Steam may be supplied to the jackets directly from the main steam pipe.

The valve casing of the Corliss cylinder is made as a separate casting, which is bolted to the cylinder with an intermediate thin plate. There are two plates, which may be used alternately, one having an opening in it corresponding to the port area, while the other is blank, so as to shut off the cylinder from the steam chest. In this way when the blank plate is in place and the valves are operated under steam pressure (the other engine giving the motion through the crank shaft), the amount of steam which leaks past the valve when closed can be drawn off by itself and conducted to the measuring vessel. It is arranged that the measuring vessel and drawing-off passage are in communication only when the valve is closed, and in addition, by first admitting steam to the measuring vessel and throttling it on opening its exhaust pipe, the conditions of pressure on the two sides of the main valve are made to approximate those occurring during actual running. Indicator cards can be taken in the measuring vessels to show the rate of variation of pressure in them, due to leakage, while the valves are in motion. Allowance is to be made for the condensation taking place in the vessel by taking the temperature of the walls and finding the condensation area from this and the cards.

The surface condensers are designed with roughened surfaces in the steam space to retard the flow of the heat-giving steam and the passages for the flow of water are contracted to obtain a high velocity. The condenser consists virtually of two concentric tubes, the water flowing in the space between them and the steam filling the space inside the inner tube and outside the outer tube. It is believed that the additional pumping power that may be needed for any increased surface friction, will be compensated for by higher efficiency and reduction in space occupied. It is stated that a condenser of this type has effected the condensation of steam at atmospheric pressure at the rate of 113 pounds per square foot of cooling surface per hour.

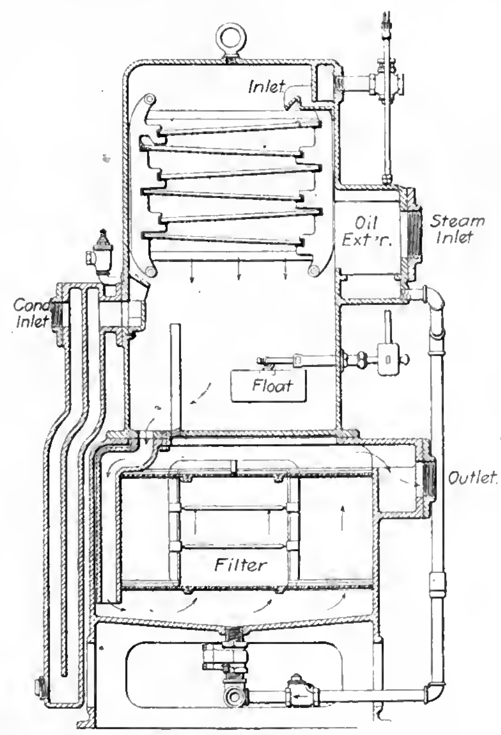
The accompanying drawings are reproduced from the article mentioned to show the general construction of a brake provided for absorbing the power of the engine. It is a band brake, consisting of two pieces of steel riveted together, one on top of the other, leaving a shallow space between for water circulation. The circulation of water in the space is very rapid, on the principle applied in the condenser. Beech slabs are bolted to the cast-iron wheel to prevent too rapid wear or the possibility of firing. The band goes once round the wheel, the tight end being fastened to the lever, and tending to raise the latter. The slack end passes over a pulley on the ceiling and back to the lever, thus tending to pull it down. The difference is recorded by means of a diaphragm and gauge. The band can be tightened by means of a screw and wheel at A. The point of application of the slack side of band to the lever can be altered by means of the screw at B.

For regulating the weight on the brake there is a novel arrangement at the opposite end of the lever. It consists of a double-walled tank, the inner wall forming an inner circular vessel. The weights which depress the brake lever have beneath them what is known as a buoyancy tank C, which is partly submerged in the inner vessel. A tap continually supplies water to the tank at a constant rate, and this water escapes at a rate which may be varied by a governing device. The bottom of the inner circular vessel is surrounded by a fixed ring on the bottom of the tank. This ring is pierced by holes, and in the bottom of the circular vessel there are corresponding holes of the same size. The circular tank is capable of turning on its vertical axis, and in this way a multi-ported valve is formed. To regulate the escape of water automatically there is a centrifugal governor, shown at D, mounted on the top of the tank and driven from the engine shaft. This by suitable mechanism operates a valve in the bottom of the tank, opening or closing it as the speed of the engine varies. By this device the acting weight on the lever is varied according to the conditions of running of the engine, as the height of water level in the inner vessel is governed by the rate of flow. The device is intended to check hunting due to cyclical variations of torque.

Dr. Nicolson points out that with a hand brake on an engine fly-wheel two things may happen. First, the co-efficient of friction between the band and wheel may vary from some cause other than change of angular velocity of the fly-wheel; or, second, a change of speed may occur due to change of steam pressure, and consequently equilibrium between brake and engine torque would be destroyed. In the first case, supposing a friction increase, then the weights and buoyancy tank will be raised, thus putting more load on the brake lever, and so tending to restore equilibrium. At the same time the speed of the engine would have diminished and the governor balls would tumble in, closing the water valve and tending to float the tank up. This would reduce the brake load, and speed up the engine again. In the second case, it is supposed the engine speed increases due to greater engine torque. This requires additional weights on the brake arm, an end which is attained by the governor balls flying out and opening the waste valve. The buoyancy of the tank is reduced, thus making the weights more effective. The co-efficient of friction between the band and wheel also diminishes with increase of speed, and so needs some correction.

The Webster Class C Heater and Purifier.

The accompanying illustration shows "Class C" type of Webster heater which has recently been placed upon the market to meet the requirements of those who desire a feed water heater of small to medium size in combination with a filter, the filter being added to make the heater particularly adapted for a feed water containing mud and salts of lime, magnesia, etc. The heater is of the open type and is in



The Webster Feed-Water Heater.

general somewhat similar to others of the same make. The feed water enters the heater through an inlet at the top and discharges into and fills a trough forming a water seal, the purpose of which is to prevent water hammer. The water overflows from the trough over a series of inclined perforated heating trays of copper, the water in its downward course being heated by steam in the heater, the water falling upon a division plate separating the heating and filtering chambers.

The filter is located in the lower casing. After the water is heated it passes through a pipe into the settling chamber at the bottom of the heater, where precipitated salts and impurities collect. The water then rises through cast-iron perforated screens which hold the filtering material and a number of screens to the under side of the division plate, whence it travels to an outlet leading to the boiler feed pump. The purpose of employing the upward method of filtration is to separate from the feed water all the precipitated salts and impurities that can be removed by sedimentation so that the filter has only to deal with the lighter impurities. As in other heaters of the Webster type, the admission of cold water is controlled by a float so that a constant level is maintained in the chamber below the inclined screens. The returns from the heating coils, steam engine jackets, reheating receivers, etc., are carried into the heater through a connection at the side provided with the water seal. Means are provided for relieving the heater of air, and a Webster oil separator is provided in the connection through which exhaust steam is admitted. The drip from the separator is connected to a blow-off pipe leading from the bottom of the heater. The makers of the heater are Warren Webster & Company, of Camden, N. J., from whom further particulars may be obtained.

Trade Publications.

The use of concrete for building purposes, in the form of patented hollow blocks, is described in a catalogue published by Harmon S. Palmer, 14th and Binney Sts., Washington, D. C., who has also patented a machine for molding the blocks. The blocks are made 9x10x32 inches, a size equivalent to 42 ordinary bricks, and of different sizes in proportion. They can be molded with different outside surfaces, as desired, and ornamented or colored for special work. The molding machines are portable and have a capacity of 150 to 200 blocks per day of 10 hours.

The Milwaukee Boiler Co., Milwaukee, Wis., has issued an illustrated catalogue of boilers, including the Reynolds' vertical and several classes of horizontal tubular boilers for both standard and high pressures, of foundry ladles, of steel stacks and of the Reynolds' feed-water heater. Boiler specifications and capacities are given in tabular form.

A discussion of the proper distribution of artificial light has been presented by the Nernst Lamp Company, Pittsburg, in a brochure showing the way in which the requirements of satisfactory illumination are met by the Nernst lamp.

The Brown-Cochran Co., Lorain, O., has prepared a nicely printed and illustrated pamphlet devoted to its lines of manufacture in ice-making and refrigerating machinery, in gas engines and in compressors. The method of refrigeration is the carbonic anhydride system; the gas and gasoline engines are built in both the vertical and horizontal types, and the compressors are provided with mechanically operated inlet valves of the Corliss type on the compressing cylinders and with the Meyer cut-off valves in the smaller sizes of steam cylinders and with the Corliss valves in the larger sizes.

The Berger Manufacturing Co., Canton, O., has issued a booklet illustrating the uses of Multiplex, a manifold plate made from black and galvanized sheet steel for floors, roofs and concrete sidewalk vault construction. The pamphlet describes also various fire-proof specialties, among which are studs, angles, furring strips and sockets for supporting metal lath, fire-proof partitions, ceiling and wall furring and luminous sidewalk lights.

The Rand Drill Co., 128 Broadway, New York City, has issued a 32-page catalogue devoted to its Imperial type of air compressors, both steam actuated and belt or gear driven. They are built in sizes of 20 to 420 indicated horse-power, the largest regular size, with a capacity of 2,394 cubic feet of free air per minute compressed to 100 pounds pressure. The book is well illustrated with cuts of the different machines, and has a corresponding number of tables of details and capacities.

The Samson windmill and the various kinds of steel towers for windmills, water tanks, etc., made by the Stover Manufacturing Co., Freeport, Ill., are described in that company's catalogue No. 552. This takes some 56 illustrated pages in which are shown the details of both mills and towers and which include some useful data regarding the power of windmills.

The importance of preserving woodwork exposed to wet or dry rot or to destruction by insects is discussed in a circular printed by Samuel Cabot, 70 Kilby Street, Boston, to introduce his "Conservo" wood preservative. This is a brownish liquid which is applied with a flat wide brush or by dipping the wood into the liquid.

A circular describing the Merrell pipe threading and cutting machines has been issued by The Fairbanks Co., Elm and Broome Streets, New York City. The machines can be run by hand or power.

The Mertes Duplex gas engine is the subject of Circular No. 2 of the National Gear Wheel & Foundry Co., for which J. D. Lyon & Co. are general agents at 331 Fourth Avenue, Pittsburg. The engines are designed for heavy duty, having ratings of 60 to 150 brake horse-power, at speeds of 180 to 160 revolutions per minute. They have poppet valves, a centrifugal throttling governor and electric ignition.

The C. O. Bartlett & Snow Co., Cleveland, O., has issued its general catalogue No. 7, a book of 288 pages covering machinery for cereal, flour and cement mills, elevating and conveying machinery, dryers and general mill supplies. It is profusely illustrated and contains descriptive matter, tables and price lists of the machinery. A large number of useful tables of general information are appended and ready use of the book is assured by an extended index.

To record some recent work done in the field of high-speed electric inter-urban railway engineering by Westinghouse, Church, Kerr & Co., New York, has taken 100 pages of a book entitled "Work Done." In addition to an extended description of several electric railway and power developments, there are numerous reproductions of working drawings and full-page half-tones from photographs of the different installations.

The Stephens-Adamson Manufacturing Co., Aurora, Ill., has prepared a pamphlet given up to its system of belt conveyors, including both self-oiling dust-proof and standard carriers. The inclined or troughing rollers turn on a spindle which is submerged and which revolves in oil.

The Joseph Dixon Crucible Co., Jersey City, N. J., is distributing a flyer on Silica-Graphite paint for the protection of heated surfaces, such as smoke stacks, boiler fronts and steel bridges.

The latest publication of the Associated Expanded Metal Companies is a 9x12-inch paper-covered book that contains about 120 beautiful reproductions from photographs of notable buildings in which the expanded metal system of fire-proof construction has been used. A copy of this valuable collection can probably be obtained from the New York Expanded Metal Co., 256 Broadway, New York.

Personal and Obituary Notes.

Maj. W. F. Robertson has been elected city surveyor of Wilmington, N. C.

Capt. T. M. McKennon has been elected chief engineer of the Blackstone & Chase City Railroad, Chase City, Va.

Mr. Schuyler Hazard, M. Am. Soc. C. E., has been appointed chief engineer of the Catawba Power Company, of Rock Hill, S. C.

Mr. Norton P. Otis, chairman of the Board of Directors of the Otis Elevator Company, has been elected to Congress from the 19th Congressional district, New York.

Mr. Edward S. Nelson has been appointed general inspector of concrete of the New York Central & Hudson River Railroad, succeeding Mr. H. Latimer, who has been transferred.

Mr. James Wilson, of Des Moines, Ia., for some twenty years with the Burlington railroad, has been appointed chief engineer of a narrow-gauge road to be built from Central City, Colo., to Yankee and Alice.

Charles Moehlman, foreman of the iron foundry of the General Electric Co., at Schenectady, N. Y., since 1895, died suddenly in that city, October 31. He was born in Westphalia in 1856 and emigrated to America in 1882.

Mr. J. D. Flack has resigned as engineer for the International Lithoid Co., to accept an appointment as erecting engineer and superintendent with the A. D. Granger Co., contracting engineers, 95 Liberty Street, New York.

James Campbell, superintendent of construction in the early days of the Southern Pacific Railway, died November 9 at Salt Lake City of pneumonia, aged 70 years. He was the first superintendent of the Salt Lake division of that road.

Julius F. Munckwitz, supervising architect and superintendent of parks of New York City from 1871 to 1884, died November 10 aged 71 years. He was first connected with the parks in 1857. Since 1884 he practiced his profession as architect.

Mr. Roger B. Williams, Jr., Jun. Am. Soc. C. E., and Mr. Ezra B. Whitman have formed a partnership under the firm name of Williams & Whitman, with an office in the Fuller Building, New York City, for the practice of civil and sanitary engineering.

Mr. Aug. Freihoff and Mr. J. Leon Wieland have purchased the business of the late A. M. Patitz and have established the firm of Freihoff & Wieland, as consulting mechanical and electrical engineers and superintendents, Germania Building, Milwaukee, Wis.

Mr. Owen L. Ingalls, assistant engineer, Department of Sewers, District of Columbia, has been appointed engineer in charge of waterworks and sewers in Manila, P. I. He was graduated from Cornell University in 1886 and has held his present position since July, 1890.

Prof. Estevan A. Fuertes has resigned as director of the College of Civil Engineering, Cornell University, on account of ill health, but The Engineering Record is glad to note that he will be able to remain in the faculty of the University as professor of astronomy in charge of the General A. C. Barnes observatory.

Civil Engineers E. H. Brownell, E. R. Gayler and P. L. Reed, U. S. N., whose appointments were recently noted in this column, have been ordered to the Portsmouth, N. H., the Brooklyn and the Boston Navy Yards, respectively. Passed Assistant Engineer R. Crawford, U. S. N., has been assigned duty at Cramp's shipyard at Philadelphia, as assistant inspector of machinery.

Prof. Ogden Nicholas Rood, the head of the department of physics in Columbia University for the last thirty-eight years, died of pneumonia at his home in New York, November 12, at the age of 71 years. He was graduated from Princeton in 1852, from Yale in 1854 and studied at the Universities of Munich and Berlin. Among his foremost achievements may be mentioned the application of stereoscopic photography to the microscope, the measurement of the duration of flashes of lightning and the making of a photometer independent of color. He was a member of many societies of both science and art, and was at one time vice president of the American Association for the Advancement of Science.

CONTRACTING NEWS

OF SPECIAL INTEREST TO

CONTRACTORS, BUILDERS, ENGINEERS AND MANUFACTURERS

OF ENGINEERING AND BUILDING SUPPLIES.

For Proposals see pages xv, xviii and xxvii.

WATER.

Great Barrington, Mass.—In a rough estimate T. H. McKenzie, of Hartford, Conn., places the cost of building the concrete dam, 40 ft. high, which would be necessary to convert the waters of Goodale Brook into a gravity water supply for this district, at $50,000.

Hammonton, N. J.—Jas. L. O'Donnell, Secy. Water Comrs., writes that the following bids were opened Nov. 7 for furnishing and erecting 2 500,000-gal. compound duplex steam pumps, 2 100-H.-P. boilers, heater and boiler feed pump and steam fitting; E. Keeley Co., Williamsport, Pa., $7,242; Henry A. Miller, Wilmington, Del., $6,111 (awarded).

New York, N. Y.—Bids are wanted Nov. 20 for furnishing, delivering and laying water mains in Claremont, Convent, Gerard and numerous other streets in the Boroughs of Manhattan and Bronx; the time allowed to complete the whole work will be 300 days, and the amount of security required $20,000. Robt. Grier Monroe, Comr. Dept. of Water Supply, Gas and Electricity.

North Beaver Township, Lawrence County, Pa.—The Cascaskee Water Co., of this place, has been incorporated, with a capital of $50,000 John B. Brown, Pres.; John P. Graham, of Moravia, Vice-Pres.; Jas. E. Mooney, of New Castle, Treas., and Stuart Thompson, Secy.

Newark, N. J.—Application for this city to furnish a water service has been made by property owners of Silver Lake and Soho Park sections of Belleville.

Washington, D. C.—The Comrs., D. C., have ordered that the sum of $50,000 be taken from the water fund and used for continuing the extension of the high-service system of water distribution.

The Northeastern Suburban Citizens' Asso. has again requested of the Comrs. that water pipes be extended to Langdon.

Wilmington, Del.—Local press reports state that the Superior Court of Delaware having decided that the Water Dept. of this city has a right to purchase land for reservoir purposes, it is expected that the work on the new basin will begin in the immediate future.

Allentown, Pa.—The Water Bd. is stated to have employed J. W. Hill, of Cincinnati, to recommend a plan to bring in and store the water from Schantz's Spring.

Walnutport, Pa.—The State Department has granted a charter to the Walnutport Water Co., with a capital stock of $1,000. The incorporators are: Alvin F. Newhart and Benjamin W. Roth, Treas., of Walnutport; Wilson F. Andrews, of Slatington, and others.

Quogue, N. Y.—The Quantuck Water Works Co., of Westhampton Beach, has been incorporated, with a capital of $100,000. Directors: J. P. Howell, Henry Gardiner and E. F. Post, of Quogue, and others.

Steelton, Pa.—The Boro. Council has sold $80,000 water bonds.

Keeseville, N. Y.—The Village Bd. has under consideration a proposition from the J. & J. Rogers Co., of Ausable Forks, N. Y., to provide the village with a new source of water supply (Gay Brook), to pipe said water to a reservoir near the village pumping station. Estimated cost of proposed plant, $30,000.

McKeesport, Pa.—The Bd. of Water Comrs. has decided to employ an expert engineer to make a recommendation as to the best plan the Bd. can adopt to secure a better water supply for the city. The Comrs. have under consideration the purchase of a section of ground about five miles up the river on which to erect a new reservoir.

Buffalo, N. Y.—The Bureau of Water is to extend the water mains by laying 16-in. pipe in Marilla and Fletcher Sts. Estimated cost, $8,000.

Bern Township, Berks County, Pa.—The Glenside Water Co., of this place, has been incorporated, with a capital of $3,000.

Bayonne, N. J.—Bids will be received Nov. 18 by the City Council for $22,000 water bonds. W. C. Hamilton, City Clk.

Lancaster, Pa.—The American Spring Water Co., John F. Stauffer, Pres., has made a proposition to the city to furnish water, asking for a 30 years contract, the minimum rental to be $30,000 per year.

Rochester, N. Y.—The Common Council has authorized Comr. McClintock to secure the title to Cobb's hill reservoir site either by purchase or condemnation proceedings. The estimated cost of the 55 acres of landed needed is $110,000. This acreage will accommodate a reservoir with a capacity of 70,000,000 gals. at an estimated cost, with necessary piping, of $572,000, making the cost of land and reservoir $682,000.

Alexandria, Va.—Walter Roberts, Pres. of the Alexandria Water Co., has recommended the construction of a reserve reservoir.

Elyria, O.—This city has contracted with the New York Continental Jewell Filtration Co. for a filter plant of 2,000,000-gal. capacity per day. The source of the supply is Lake Erie.

The following bids are reported to have been received by the Water Works Trus. for the erection of the pumping station and filter plant buildings for the new water works: Jacob Meyer, Lorain, $21,950 (awarded); Bonsor Bros., Lorain, $22,205; Fred Wolf, Elyria, $22,450.

Cincinnati, O.—The Bd. of Water Works Comrs. is said to be preparing to issue $1,000,000 water works bonds in February.

Mallard, Ia.—Recorder J. W. Johnson writes that the contract for constructing water works has been let to the Des Moines Bridge & Iron Wks., Des Moines, Ia., for $6,500.

Ottumwa, Ia.—City Engr. John T. Brady writes that bids will be received Dec. 1 for furnishing approximately 470 net tons of 16, 14, 12, 8 and 6-in. cast iron water pipe, and 19,000 lbs. of specials, to be delivered on or before Feb. 1, 1903; bids will also be received at the same time for the laying of said pipe on or before Apr. 1, 1903.

Waukegan, Ill.—Bids are wanted Nov. 17 for 5,760 ft. of 12-in. cast iron water pipe with 3 valves and 1 fire hydrant, to be laid in certain streets. H. Thacker, City Clk.

North Milwaukee, Wis.—This village has sold $30,000 bonds for a new water works system.

Harrison, O.—The village is considering the purchase of the water works and the lighting plant, now owned by Jas. Graft, which supplies the village.

Ashtabula, O.—Plans for a new water works system and supply at Ashtabula are reported to have been approved by the State Bd. of Health.

Indianapolis, Ind.—The Bd. of Pub. Wks. has ordered the Indianapolis Water Co. to proceed with its extension of water mains to Irvington. The order of the Bd. is for about 8 miles of mains and involves the putting in of about 50 fire hydrants.

Cleveland, O.—The Bd. of Control has authorized the Dir. of Pub. Wks. to contract with the Babcock & Wilcox Co. for the installation at Kirtland St. pumping station of a battery of 6 boilers, equipped with steel superheater and automatic stokers. Cost $43,454.

Columbus, O.—A committee, composed of Professors Ray, Bonnocker, Sherman and others, has under consideration the recommendation that the Ohio State University install an independent water plant.

Castana, Ia.—The Castana Water Co. has been incorporated with a capital of $4,000, to erect, establish and maintain a system of water mains in Castana. W. L. Wiley, Pres.; J. E. Kintigh, Secy.; C. W. Norcross, Vice-Pres., and W. W. Gingler, Treas.

South St. Paul, Minn.—Bids are wanted Dec. 1 for the construction of a standpipe and laying water mains to the pumps of Swift & Co. Chas. W. Clark, City Recorder.

Findlay, O.—City Engr. John W. S. Riegle writes that bids will be received Nov. 25 for laying 10.6 miles of 24-in. vitrified pipe, or 10.6 miles of 20-in. cast-iron pipe, with well connections, etc.

Gillett, Wis.—Village Clk. L. B. Studke writes that bids are wanted by the Village Council until Dec. 29 for the construction of water works, estimated to cost $6,000.

Burlington, Ia.—This city has voted in favor of granting the Citizens' Water Co. the exclusive right to acquire, operate, improve, extend and maintain the system of water works now constructed in this city for a period of 20 years.

Lake Linden, Mich.—Local press reports state that this town proposes to install municipal water works and an electric light plant.

Mount Carmel, Ill.—The Citizens' Light & Water Co. has been incorporated with a capital of $70,000. Incorporators: A. R. Manley, P. G. Manley and J. M. Mitchell.

Moline, Ill.—The City Council has decided to purchase the high-duty pump, 6,000,000 gal. capacity, of the Holly Mfg. Co., Lockport, N. Y., at its bid of $24,430, of which $1,680 is for connections. In his report Engr. Dan. W. Mead recommends that the bid of the New York Continental Jewell Filtration Co. be accepted for the construction of a filter system at a cost of $67,377.

Ardmore, Ind. Ter.—City Clk. G. H. Bruce writes that the piping for the $150,000 water works has been purchased, and work will begin in Dec. Engr. in charge, Chester B. Davis, of New York City.

El Paso, Tex.—City Engr. Geo. C. Wimberly writes that a water works franchise has been granted to W. J. Davis and associates of Los Angeles, Cal., for a term of 35 years.

St. Louis, Mo.—The ordinance appropriating $110,000 for alterations in the settling basins at the Chain of Rocks has been given its first reading in the City Council.

Sapulpa, Ind. Ter.—At the recent election $25,000 bonds are reported to have been voted for water works and $15,000 bonds for schools.

Lake Charles, La.—The charter of the Fresh Water Co. has been filed for record. The company is capitalized at $300,000. The officers are: J. W. McFatter, Pres.; F. C. Baker, Vice-Pres.; J. R. Lyles, Treas.; J. E. Gilsson, Secy., and J. E. Bland, Gen. Mgr., all of Calcasieu Parish. The company proposes to build a canal from Calcasieu River across to Great Calcasieu Prairie, east of Fenton, La.

Ft. Leavenworth, Kan.—The Secy. of War has appointed a Bd. of Officers, consisting of Col. Chas. W. Miner, Maj. S. S. Leach, Corps of Engrs., and others, to meet at Ft. Leavenworth to inquire and report upon the subject of water works at that post.

Eagle Lake, Tex.—The proposition to issue bonds for building a water works plant, is reported to have carried.

Harrodsburg, Ky.—The water works and electric light bond issues are reported to have carried at the recent election.

Lawton, Okla. Ter.—The City Council is reported to have awarded to Cook & Son, of Junction City, Kan., the contract for constructing water works for $104,959. The contract provides for 9 miles of mains, a power house, pipe and reservoir, all to be completed in 6 months after the Secretary signs the contract. Local press reports state that the United States Government pays for the entire system, and it then becomes the property of the city, and that sewers are to be built later in the same way.

Bay City, Tex.—Local press reports state that water works and electric light systems are to be built.

Covington, Tenn.—The City has purchased the water works for $14,720.

Memphis, Tenn.—The Water Com., of which Edw. B. Le Master is Chmn., has recommended that the city acquire possession of the Artesian Water Co.'s plant, and Com. also recommends an increase of fire hydrants.

Wagoner, Ind. Ter.—Bids are wanted for $160,000 corporation water works bonds. C. A. Rees, Fayetteville, Ark.

Ft. Romie, Cal.—The Ft. Romie Water Co. has been incorporated by A. James, N. A. Erickson, E. Harding and others, with a capital of $6,750. Principal place of business, Soledad.

Salem, S. D.—Bonds to the amount of $6,000 are reported to have been voted for a system of water works.

Wessington, S. D.—The proposition to issue $2,500 artesian well bonds carried.

Fargo, N. D.—An improved water supply is urged. Larger water mains in the business portion are proposed.

Colorado Springs, Colo.—Mayor John R. Robinson, in a communication to the City Council, recommends the appointment of an expert hydraulic engineer to take charge of Colorado Springs water works system.

Fort Lupton, Colo.—The Lake Lupton Irrigating & Reservoir Co. has been incorporated, with a capital of $40,000, to operate in Weld County. Principal office, Ft. Lupton. Directors: T. C. Winbourn, H. B. Cave, R. W. Haynes and others.

Ft. Flagler, Wash.—Col. J. H. Hathaway, Ch. Q. M., and Col. Timothy E. Wilcox, Ch. Surgeon of the Dept. of the Columbia, U. S. A., are said to be considering plans for securing an adequate water supply for Fort Worden, Ft. Flagler and Ft. Casey.

Pueblo, Colo.—The North Side Water Works Trus. have ordered plans and specifications for a pipe line from 6th St. and Grand Ave. to Fairmount Park.

Marion, S. D.—The construction of a water works system for fire protection is said to be under consideration.

Armour, S. D.—The city authorities are considering the matter of providing a new supply of water for domestic and fire protection purposes.

Los Angeles, Cal.—It is stated that bids are wanted Nov. 24 for a pumping plant at Buena Vista, consisting of a double-acting duplex pump of 4,500 gals. per minute, lifted to a height of 230 ft., or a vertical inverted engine, and 2 water-tube boilers. Wm. Mulholland, Supt. of Water Wks.

Brandon, Manitoba.—The City Council has resolved to make improvements to the water works plant to the amount of $25,000; improvements to include the installation of new machinery and the extension of water mains.

Stratford, Ont.—The City Council has passed a resolution to submit a by-law to the people to acquire the water plant and mains of the Stratford Water Supply Co., for $95,000.

SEWERAGE AND SEWAGE DISPOSAL.

Waterbury, Conn.—This city is considering various plans for the disposal of sewage, one plan which provides for a chemical precipitation of the solid matter with subsequent land filtration of liquid matter near Platt's Mills, would require an investment of at least $400,000, according to local press reports, with an annual cost of operation amounting to about $28,000.

Medford, Mass.—The Comrs. of Sewers have ordered the construction of a sewer in Irving St., work to be done under the direction of City Engr. W. Gavin Taylor.

Northampton, Mass.—Engr. Bowditch, of the State Bd. of Health places the estimated cost of the proposed extension of the Northampton sewer system to the Connecticut River at over $100,000. The Sewer Comrs. (L. M. Thacher, Engr.) have petitioned the city government for an appropriation of $50,000 for the extension.

West Hoboken, N. J.—The Town Council on Nov 5 adopted a resolution directing the Com. on Streets and Sewers to present to the Council plans, estimates, etc., for additional relief sewers. According to plans prepared by Sebastian Maulbeck, Town Surveyor, the estimated cost of said sewers is $30,000.

New York, N. Y.—Bids are wanted Nov. 20 for the construction of a pipe sewer and appurtenances from the Public Comfort House in the North Meadow to existing sewer near 99th St. and 5th Ave., all in Central Park. Wm. R. Willcox, Comr. of Parks.

Bids are wanted by Geo. Livingston, Comr. of Pub. Bldgs., until Nov. 18 for repairs to sewer in Stanton St.; security required $10,000. Also for repairs to sewer in 12th and 13th Aves., in 27th, 28th, 29th and 30th Sts.; amount of security required $7,500.

Canajoharie, N. Y.—Morrell Vrooman is reported to have been engaged to prepare plans and specifications for the sewer system, for which $36,000 bonds were recently voted.

Reading, Pa.—A plan is said to be under consideration for the issue of $400,000 bonds for public improvements, including the construction of certain sewers and a bridge at Spring St.

Glassport, Pa.—This Boro. has voted to issue $60,000 bonds for sewer work, street work and general improvements.

Brooklyn, N. Y.—Bids will be received Nov. 26 by J. Edw. Swanstrom, Boro. Pres., for furnishing material and constructing a sewer in portions of Ovington Ave. and outlet sewers in portions of Silliman Pl. and Second Ave. Engineer's estimate is as follows: 1,750 lin. ft. 12 and 18-in. vitrified stoneware pipe sewer laid in concrete, 19 manholes, 4 receiving basins and 11,600 ft. B. M. foundation planking.

Mt. Vernon, N. Y.—City Engr. Geo. W. Drumheller writes that Snow & Barbour, of Boston, Mass., have commenced surveys for revised map of sewer system for Chester Hill and Corcoran Manor Districts of this city.

Johnstown, N. Y.—The Sewer Com. has recommended the construction of a 12-in. trunk tile sewer through Market and other streets. Total length 2,400 ft.

Corinth, N. Y.—Village Engr. S. J. Mott has placed the estimated cost of the Palmer St. sewer system at $8,321.

Bradley Beach, N. J.—Bids will be received Nov. 20 by Wm. E. MacDonald, Boro. Clk., for constructing sewers in said Boro.

Depew, N. Y.—Bids will be received Nov. 17 by the Bd. of Village Trus. for furnishing material and constructing lateral sewers. J. C. Glade, Village Clk.

Easton, Pa.—The Finance Com. has reported to the Common Council having approved the ordinance providing for the increase of the city debt $300,000 for the purpose of improving streets and the sewerage system.

Penn Yan, N. Y.—Wm. T. Morris, of Penn Yan, and associates have petitioned the Village Bd. of Trus. for a franchise to lay a complete system of sewers in the village.

Leetsdale, Pa.—The Leetsdale Drainage Co. has been incorporated, with a capital of $10,000.

Crafton, Pa.—Bids will be received Dec. 2 by W. O. H. Elliott, Boro. Clk., for $25,000 bonds, to be used for improving sewers, streets, etc.

Bond Hill, O.—Village Clk. A. J. Kiphart writes that on Nov. 4 it was voted to issue $40,000 bonds for the construction of a sewerage system for the suburbs.

Grand Rapids, Mich.—The City Council on Nov. 3 instructed the Bd. of Pub. Wks. to reject all bids opened Oct. 17 for the construction of a sewer along the West Side Ditch, and to ask for new bids to be received Feb. 1. The work contemplated comprises the construction of a concrete and concrete-metal sewer of about the following lengths and dimensions: 2,305 ft., 7.5 ft. in diameter; 2,207 ft., 7 ft.; 2,633 ft., 6.5 ft.; 1,585 ft., 5 ft.; 1,959 ft., 4.75 ft.; 461 ft., 4.5 ft.; 2,588 ft., 4 ft., and 1,287 ft., 3.5 ft. in diameter. L. W. Anderson, City Engr.; John C. Brown, Clk. of Bd. of Pub. Works.

Des Moines, Ia.—Bids will be received Dec. 2 by the Bd. of Pub. Wks. for constructing 12-in. vitrified clay pipe sewers, about 3,690 lin. ft., in portions of 3 streets. J. E. Stout, Chmn.

Clinton, Ia.—City Engr. Chas. P. Chase writes that it is expected to commence work in the spring upon the sewerage system, for which he is preparing plans. Estimated cost $250,000 to $300,000.

Jerseyville, Ill.—The City Council is reported to have let the contract for the first system of sewers to Wolfe, Maupin & Curdie, Alton, Ill. The sewer system will be 4,000 ft. in length, 10 and 12 in. in diameter.

Peoria, Ill.—The City Council has authorized the construction of 3 sewer systems; total estimated cost $141,390. The North Peoria sewer system, which is estimated to cost $87,970, includes 5,000 ft. of tunnel, to run 80 ft. below the surface.

Washington, Ia.—This city is said to be planning additional sewers.

Racine, Wis.—The proposition to issue $55,000 sewer bonds is reported to have carried.

Columbus, O.—The Bd. of Pub. Wks. has recommended to the Council for passage ordinances authorizing the construction of central relief sewers in the Long St. Dist., Walnut St. relief sewers and a system of sewers on the West Side north of Broad St.

The contract for the construction of sewers in West Side sewer Dist., Section A, has been awarded to J. B. Sheets & Co., of Pittsburg, for $51,840.

Indianapolis, Ind.—The Bd. of Wks. has taken final action on ordinance for a local sewer in Arsenal Ave. Estimated cost, $5,400.

Nashville, Tenn.—City Engr. Wm. W. Southgate writes that the following bids were opened Nov. 6 for constructing the Edgefield Branch sewer work, to include 5,000 ft. of 9 ft. 3 in. to 11 ft. brick sewer, with 16 manholes, average depth of excavation 5½ ft. in earth: Lightman & Butler, Nashville, $66,317; Patterson & Brieson, Baltimore, Md., $86,767; Nashville Plumbing Co., Nashville, $66,224; Henry Herman (U. S. Const. Co.), Cincinnati, O., $84,251; J. T. Allen, Nashville, $69,439; Pease & Davidson, Nashville, $66,942; E. T. Lewis Co., No. Front St., Nashville, $59,895. The contract has been awarded to the E. T. Lewis Co., its detail bid being as follows: Excavating 16,882 cu. yds., 35 cts.; brick work, plain, 5,061 M, $10.60; brick, radiated, 1½ M, $10.60; masonry, 10 cu. yds., $8; concrete, 10 cu. yds., $8; iron casting, set, 8,080 lbs., total $15; 18-in. pipe, 200 ft., 70 cts.; 15-in. pipe, 30 ft., 50 cts.; 12-in. pipe, 30 ft., 40 cts.; 6-in. pipe, 225 ft., 15 cts.; 30-in. pipe, 25 ft., $2; 24-in. pipe, 20 ft., $1.25.

Lawton, Okla. Ter.—See "Water."

Gueydan, La.—The syndicate that bid in the work of excavating 24 miles of drainage canals between this town and Grand Lake, was organized Nov. 8 into the Inland Canal Co., capitalized at $100,000, with the following officers and directors: J. M. Booze, of Roanoke, La., Pres.; T. J. Curtis, Vice-Pres.; Henry L. Gueydan, Secy. and Treas.; C. D. Babbit, V. Wainwright, D. L. McPherson, of Abbeville, and Bernard Titche, of New Orleans. Work is to begin before Jan. 1, 1903. C. D. Babbit is the Engr. of the Co.

The following bids were opened Nov. 4 for approximately 500,000 cu. yds. of dredge work on Canals A, Vermilion Parish: E. B. Connors, New Orleans, at 8.39 cts.; Menzler & Co., New Orleans, at 7.875 cts.; H. L. Gueydon, Gueydan (awarded), at 7.47 cts. No bids were received on Canals B, Vermilion Parish, for 43,000 cu. yds. of dredge and scraper work.

New Orleans, La.—The Executive Com. of the Sewerage & Water Bd. has reported favorably on the acceptance of the bid of the Camden Iron Works for furnishing steam and electrical equipment to the pumping stations, amounting to $246,000. The Com. also recommends that after specifications are modified so as to make a larger number of smaller contracts for the construction of sewer work, new bids be asked to be opened Feb. 2.

Houston, Tex.—Local press reports state that it will cost several thousand dollars to repair the filter beds of the sanitary sewer plant. Dr. W. M. Brumby, City Health Officer, may give further information.

Hannibal, Mo.—An extensive culvert and sewerage system is to be constructed on Grand Ave. in order to convert this thoroughfare into a boulevard. The improvement, it is estimated, will cost about $10,500.

North Yakima, Wash.—Ernest McCullough, of Lewiston, Idaho, has been engaged to prepare plans for a sewer system for this city, also for underdraining for city; estimated cost $60,000.

Flagstaff, Ariz.—A special election has been called for Dec. 8 to vote on the issue of $9,500 bonds for the purchase and improvement of the sewer system. L. W. Quinlan, Town Clk.

Los Angeles, Cal.—At the recent election it was voted to issue $1,000,000 bonds for outfall sewers and $400,000 bonds for storm drains.

Fairbury, Neb.—Press reports state that the Sewer Co. will extend the sewer system.

BRIDGES.

Boston, Mass.—Bids are wanted Dec. 1 for constructing Wellington bridge, Middlesex Fells Parkway, Somerville and Medford. Total length of bridge about 950 ft. Wm. B. De Las Casas, Chmn. Metropolitan Park Comn.

Bemuspoint, N. Y.—There is reported to be a movement on foot in Chautauqua County looking to the construction of a bridge across "The Narrows," near Bemuspoint, to cost about $50,000. At a meeting held here Nov. 1 an organization was perfected, with Jared Hewes Pres. and Henry W. Flabavens, Secy.

West Albany, N. Y.—A press report states that the N. Y. Central & Hudson River R. R. Co. will construct a 9-track bridge over Schenectady turnpike. W. J. Wilgus, Ch. Engr., New York.

Pittsburg, Pa.—The Pittsburg & Washington St. Ry. Co. is stated to have awarded to the McClintic-Marshall Construction Co. of Pittsburg the contract for the construction of 3 steel viaducts, one 1,000 ft. long, another 480 ft. long and the third 270 ft. long.

Glenolden, Pa.—The Boro. Council is stated to have passed an ordinance granting the Philadelphia, Baltimore & Washington R. R. Co. the privilege of building an overhead bridge at Ashland. The company is required to macadamize Ashland Ave. from Linwood Ave. to the pike, for a width of 19 ft., and make other improvements.

Braddock, Pa.—The American Steel & Wire Co. is stated to have petitioned the Boro Council for permission to construct 3 overhead bridges at its 9th St. plant.

Erie, Pa.—The Council on Nov. 6 passed an ordinance providing for the construction of a bridge on the Buffalo Road over the Phila. & Erie R. R. tracks, to cost $45,000. The Pennsylvania R. R. Co. (W. W. Brown, Ch. Engr., Philadelphia) and the Erie Motor Co. will each pay part of the construction.

Washington, D. C.—Col. John Biddle, Engr. Commr. of the District, in his annual report recommends that the K St. bridge over Rock Creek be rebuilt at a cost of $20,000. He also calls attention to the serious condition of the Anacostia bridge.

Baltimore, Md.—Bids are wanted Nov. 24 for the construction of a steel bridge over Patapsco (north branch). Estimated cost $2,000. W. W. Crosby, Baltimore Co. Roads Engr.

Boyds, Md.—The County Comrs. Rockville, Md., have decided to change the roadway near Neelsville, so as to allow a bridge to be built over Little Seneca stream on the road leading from Clarksburg to Neelsville.

Franklin, Pa.—Bids are wanted Dec. 9 for furnishing material and constructing the superstructure and substructure for a steel bridge over the Allegheny River at Scrubgrass. J. M. Black, Chmn. of Co. Comrs.

Castlemans Ferry, Va.—The citizens of Clarke County are stated to have voted Nov. 4 to issue $40,000 bonds for the construction of a steel bridge across Shenandoah River at Castlemans Ferry (Berryville, C. H.).

Youngstown, O.—The citizens are stated to have voted Nov. 4 to levy a tax for the construction of a bridge over Mill Creek at the w. end of Mahoning Ave.; probable cost $140,000.

Geneva, O.—The Ashtabula Co. Comrs. are reported to have been here consulting with Jas. Ritchie, Ch. Engr. of the C. P. & A. Ry., in regard to constructing a wider bridge over Cowles Creek on E. Main St. (Jefferson, C. H.).

Cincinnati, O.—City Engr. Stanley is stated to have been directed by the Bd. of Pub. Service to prepare plans for a steel viaduct at Ida St.

A press report states that Martin Brodbeck, Chmn. of the Comn. on Track Elevation, has introduced in the Bd. of Legislation an ordinance to abolish the Harrison Ave. grade crossing. Arrangements were once made to build a viaduct there at a cost of $270,000, but the courts enjoined the work. The cost will now be paid as follows: 50 per cent. by the Baltimore & Ohio R. R. Co. (J. M. Graham, Ch. Engr., Baltimore, Md.), and C., H. & D. R. R. Co. (C. A. Wilson, Ch. Engr., Cincinnati); 25 per cent. by the city and 25 per cent. by the Traction Co. (J. R. Heizenecker, Ch. Engr., Cincinnati).

Andrews, Ind.—Citizens of Andrews and Dallas Townships are stated to have petitioned the County Council, at Huntington, for an appropriation of $16,000 for a bridge across Wabash River at Andrews.

Newport, Ind.—The Chicago & Eastern Illinois R. R. Co. is stated to have decided to erect two 70-ft. steel bridges. W. S. Dawley, Ch. Engr., Chicago.

Chillicothe, Ill.—The Santa Fe R. R. Co. is stated to have decided to erect a steel bridge across the river above Chillicothe. Jas. Dun, Ch. Engr., Chicago.

Chicago, Ill.—The lowest bids opened Nov. 5 by the Drainage Bd. for the bascule bridges to span the Chicago River at Loomis and 18th Sts., are stated to have been from the Lydon & Drews Co. for the substructure of both bridges, $62,728 for the Loomis St. and $70,716.40 for the 18th St., and the Jackson & Corbett Co., for the superstructure $121,620 for Loomis St. and $115,870 for 18th St.

Detroit, Mich.—The citizens on Nov. 4 voted to issue $600,000 bonds for the construction of a second bridge, to be placed at the upper end of Belle Isle.

Portsmouth, O.—City Clk. Frank L. Sikes writes that it is proposed to construct a bridge across Funk's Gut. Engr. in Charge, B. C. Bratt.

Jonesboro, Tenn.—Bids are wanted for constructing an iron bridge across the Nolichucky and Watauga Rivers. Address H. J. De Pew.

St. Joseph, Mo.—It is stated that bids are wanted Nov. 20 for constructing a bridge at Ablf. Theo. Steinacker, Co. Surveyor.

Manhattan, Kan.—Bids will be received Nov. 22 by the Bd. of Fancy Creek Township for constructing 3 arch bridges on Walnut Creek, 1 between Jackson Township and 2 between Sherman Township and Fancy Creek. E. B. Senn, Clk.

Chehalis, Wash.—Co. Aud. A. Schooley writes that new bids have been asked until Dec. 1 for the construction of a bridge across Cowlitz River at Mayfield, span to be 140 ft. long.

Sidney, Neb.—Bids are wanted Nov. 24 for building a bridge across the Lodgepole Creek. Jas. Burns, Co. Clk.

Los Angeles, Cal.—The citizens voted Oct. 29 to issue $100,000 bridge bonds.

PAVING AND ROADMAKING.

Swansea, Mass.—At a special town meeting held recently it was voted to appropriate $6,000 to construct the proposed road from Bark St. to Somerset town line.

Meriden, Conn.—The Bd. of Pub. Wks. is said to be in favor of the paving of Colony St. from the end of the asphalt now laid to Camp St. Estimated cost $14,000 if asphalt is used, or $10,000 if macadam is used.

Newport, R. I.—At the recent election bonds to the amount of $50,000 were voted for bituminous macadam pavement on Broadway and Spring St.

Crafton, Pa.—See "Sewerage & Sewage Disposal."

New York, N. Y.—Bids are wanted Nov. 18 for regulating and repaving with asphalt on present pavement relaid as foundation, numerous streets of the Boro of Manhattan, in all 101,275 sq. yds. of asphalt pavement, including binder course. Bids are also wanted for paving with asphalt block in certain streets, in all 8,365 sq. yds. of asphalt block: also for 6,800 sq. yds. of granite block pavement on concrete foundation in New Elm St. Geo. Livingston, Comr. of Pub. Works.

Bids are wanted Nov. 20 for paving with granite block 2,830 sq. yds., on sand foundation, in E. 163d St., also for 1,320 sq. yds. of granite block repaving; for 1,030 sq. yds. of asphalt block pavement, 2,475 sq. yds. of sheet asphalt pavement with binder course, and 2,150 lin. ft. of curbstone reset in E. 171st St.; for 3,000 sq. yds. of repaving with new granite block and 4,800 sq. yds. of granite block pavement on a concrete foundation in E. 138th St.; for 7,205 sq. yds. of macadam pavement on telford foundation in E. 183d St.; for granite block pavement on a sand foundation in Tremont Ave., the engineers' estimate including 23,800 sq. yds. of pavement, 5,000 lin. ft. of new curbstone, 4,600 ft. old curbstone reset, 4,000 sq. ft. of new bridge stone, 5,800 sq. ft. of old bridge stone relaid, 33,000 sq. ft. of old flagging relaid, 4,000 sq. ft. new flagging, and 13 receiving basins to be rebuilt. Louis F. Haffen, Pres. Boro. of Bronx.

Windsor, N. Y.—A. N. T. Back, Chmn. County Bd. of Superv., Binghamton, has received from State Engr. Bond plans and specifications for the improvement of the following roads in Broome Co.: River road, Windsor, section 1, length, 1.868 miles, total estimated cost $16,450, the county's share being $8,225; River road, Windsor, section 2, length, 2.838 miles, the total estimated cost $25,900, the county's share being $12,950.

Duquesne, Pa.—Local press reports state that the Pittsburg, Virginia & Charleston R. R. proposes to macadamize a road 33 ft. wide between Duquesne and Dravosburg.

Easton, Pa.—See "Sewerage and Sewage Disposal."

Swarthmore, Pa.—This borough has voted in favor of borrowing $20,000 for road repairs.

Pennington, N. J.—See "Electric Railways."

Pittsburg, Pa.—Bids are wanted Nov. 29 for the purchase of $550,000 bonds, to be used for building, improving and repairing public roads, highways, etc. W. E. Thompson, Co. Compt.

Glenolden, Pa.—See "Bridges."

Glassport, Pa.—See "Sewerage and Sewage Disposal."

Brooklyn, N. Y.—A petition has been presented to the borough authorities to have 65th St. from the bay to 4th Ave. paved with asphalt. The total estimated cost is placed at about $50,000.

Syracuse, N. Y.—Bids are wanted Nov. 17 for furnishing material and paving with sheet asphalt or vitrified brick, portions of Warren and Willow Sts. Geo. J. Metz, City Clk.

Kent, O.—The lowest bid received for paving Water St. 9,208 sq. ft., with curbing, catch basins, sewer inlets, etc., was from Mr. Davidson, of Akron, at $17,197 for Metropolitan wire cut block.

Des Moines, Ia.—Bids will be received Dec. 2 by the Bd. of Pub. Wks. for curbing with Portland cement portions of 4 streets requiring about 9,621 lin. ft. of curbing; also on same date for paving with 1 course of No. 1 vitrified paving brick upon a 6-in. concrete foundation, with Portland cement top filler, portions of 2 streets requiring about 4,851 sq. yds. of paving. J. E. Stout, Chmn.

Local press reports state that it is proposed to pave either with brick or asphalt portions of University Ave., 35th St. and Forest Ave., in all about 40,000 sq. yds. It is estimated that the entire contract will be not less than $150,000, if paved with asphalt, and about $100,000 if paved with brick.

Toledo, O.—Bids are wanted by the Com. on Ways and Means of the Common Council until Dec. 9 for the purchase of $125,000 bonds issued for the purpose of paying the cost of repairing and improving existing streets and other public highways of the city. J. B. Wylie, City Aud.

City Engr. G. W. Tonson writes that the following bids were opened Nov. 3 for repaving (20,086 sq. yds.) on Front St.: A, Bodette & McMahon, Toledo, $33,658, vitrified blocks on concrete; $23,176.54, vitrified blocks on sand. B, C. H. Burchinal, Toledo, $52,453.56, asphalt blocks on concrete; $45,429.32, asphalt blocks on sand. C, H. G. Jennison, Toledo, $69,029.64, Medina blocks on concrete; $52,429.12 (awarded) Medina blocks on sand. For detail bids see accompanying table.

C., for the construction of the quay wall at Mare Island: Dundon Bridge & Const. Co., $47,268; Clark & Henery, $54,051.83; W. W. Coneannon, $46,742; Atlantic, Gulf & Pacific Co., $46,147; Wm. H. Healy, $48,243.

MISCELLANEOUS.

Yonkers, N. Y.—Bids are wanted by the Bd. of Park Comrs. until Nov. 20 for the construction of a wrought-iron fence in Irving Park. S. L. Cooper, Supt. of Parks.

Buffalo, N. Y.—Mayor Knight has approved the resolution permitting the Buffalo & Susquehanna Iron Co. to build a canal across Hamburg turnpike.

Chicago, Ill.—By a vote at the recent election bonds to the amount of $500,000 were authorized to be expended by the Lincoln Park Bd. for small parks on the North Side, and $1,000,000 to be expended by the South Park Bd. for a similar purpose on the South Side.

New Orleans, La.—Bids are wanted Nov. 18 for the labor and material necessary for the complete construction of a 900-ft. wharf on the river front at Julia St. Hugh McCloskey, Pres. Bd. of Comrs., Port of New Orleans.

Lexington, Ky.—By popular vote the City Council has been ordered to vote bonds for a public park and school.

Oakland, Cal.—The contract for improving 12th St. dam has been awarded to the Hutchinson, Ransome Co., for $36,000.

Ottawa, Ont.—It is said the Government has in view the erection of a park, national in character, at the eastern end of Ottawa. The scheme is intended to embrace Rideau Hall, grounds, composed of 82 acres, and the Rockliffe ranges, about 350 acres in extent.

Montreal, Que.—Plans submitted to the Government for a tunnel across Montreal Harbor are stated to provide for a double-track tunnel from the south shore into the heart of Montreal, where a central station will be located. The width will be 27 ft. and the height 21 ft. Its grade will be 1½ to 2 per cent., and its greatest depth will be 15 ft. below the mean level of the river bed. The structure will be of concrete and stone masonry with a lining of enamel brick. The course of the tunnel will pass through St. Helen's Island, where there will be a sub-station.

The City Council has decided to appoint a committee to report on the feasibility of building a tunnel under Forsythe St., so as to enable the Terminal Ry. Co. to complete its street car line into the city.

NEW INDUSTRIAL PLANTS.

The Struthers, O., Furnace Co. intends to erect a plant having a capacity of about 500 bbls. of cement made from blast furnace slag. The Osborn Engineering Co., Cleveland, has charge of the erection of the plant.

The H. L. Hurst Mfg. Co., Canton, O., maker of hardware specialties, will erect a new plant and install an additional 15-H.-P. gas engine, 6-H.-P. dynamo for lighting, and sheet metal working machinery.

Jewett & Co., Buffalo, N. Y., makers of stoves and ranges, will erect a new plant, details of which have not been decided.

W. A. Buckner, Sumter, S. C., is organizing a company to develop a kaolin bed for the making of pottery.

The Downington Mfg. Co., Ltd., East Downington, Pa., maker of machinery for paper and pulp mills, is erecting a 40x105-ft. addition to its erecting shop, making it 260 ft. long; a 75x120 ft. machine shop having a 40-ft. span in center containing heavy tools and covered with a 10-ton electric crane, and bays on either side for small tools, and a 40x75-ft. woodworking shop. The erecting shop will be equipped with a 10-ton electric crane. The plant will be driven by electricity and heated and ventilated with steam radiator and fan. A 100-Kw. generator and motors will be installed.

The St. Julien Mining Co., Livingston, Mont., expects to build a 20-stamp mill and cyanide plant. The plant will be run by water power and completed next spring.

The Southwestern Brick & Tile Mfg. Co., Ltd., 512 Macheca Bldg., New Orleans, La., will erect a plant to occupy about 1¼ acres.

The Petoskey, Mich., Rug Mfg. & Carpet Co., Ltd., will install an electric motor.

The Owosso, Mich., Sugar Co. will erect a 70x240-ft. main building and a 70x200-ft. warehouse. The contract for the complete plant has been let to the Kilby Mfg. Co., Cleveland, O.

The Michigan Lumber Co., Aberdeen, Wash., will erect a 220x42-ft. mill. The capacity of the power plant will be 170 H.-P.

The Mayfield, Ky., Brick Co. is in the market for three down-draft kilns and a dry pan.

The Detroit Foundry & Mfg. Co., 195-199 Atwater St., East, Detroit, Mich., has had plans prepared for a 100x185-ft. foundry building of steel construction, arranged so it can be extended to 350 ft., and a 30x35-ft. engine and boiler room. A 100-H.-P. engine, an 80-Kw. generator, cupolas of 10 and about 5 tons' capacity, and a 10-ton electric traveling crane, with a 40-ft. span, will be installed.

The Keever Starch Mfg. Co., Columbus, O., is erecting a 3-story, 120x180-ft. factory, to have a daily capacity of 2,500 bu. corn. The capacity of the power plant will be 300 H.-P.

The Standard Press Brick Co., Lawton, Okla., will install a plant having a daily capacity of 20,000.

The Helena, Mont., Light & Traction Co., whose plant was recently burned, will erect a fireproof structure to contain 600 Kw. in motor generators, with apparatus for distributing and 1,500 Kw. of step-down transformers. The company is now operating from a temporary plant constructed near the old site.

The Springfield, Mass., Printing & Binding Co. has let the contract for a 7-story building, 100 ft. square. A 150-H.-P. engine, a generator and motors connected to each machine will be installed. The building will be steam heated and equipped with automatic sprinklers.

Tenders and specifications for a complete plant for making magnesite bricks, to be addressed to "Brick Maker," care of the International News Co., 5 Breams Bldg., Chancery Lane, London, E. C., England, are asked for, as advertised in The Engineering Record.

BUSINESS NOTES.

The United States Coal Co. is about to equip its soft coal mines at Dillonvale, O., with electrical machinery, and for that purpose recently purchased from the Westinghouse Electric Mfg. Co. two 150-Kw., 550-volt, direct-current generators and two 10-ton mining locomotives. Electric power will be used for the operation of the locomotives and other mining machinery.

At the Dusseldorf Exhibition, which has just terminated, the highest award of merit, the gold medal, was awarded the Hunt conveyor, manufactured by the C. W. Hunt Co., West New Brighton, N. Y.

Notwithstanding the Otto Gas Engine Works, Philadelphia, added 12,000 sq. ft. of floor space to their plant less than two years ago, their ever increasing business is again crowding them, and the last available bit of ground in the block covered by the works is having a building 40x100 ft. erected on it. The demand for large units makes necessary these increased facilities, and the new building will be equipped with the largest and latest types of machine tools. The tools are ordered, and the new shop should be running inside of six weeks.

The Russell & Erwin Mfg. Co., New Britain, Conn., has placed a contract with B. H. Hibbard for the construction of a new manufacturing building, to be 50 ft. wide, 200 ft. long and 7 stories high. The construction will be fireproof throughout, and the floors will have a capacity of 250 lbs. per sq. ft., so that the building can be used for carrying all classes of manufactured goods. It is expected that this building will be completed and ready for use about Feb. 1.

P. & F. Corbin, New Britain, Conn., are making extensive changes in their plant, in order to increase the output. They have just completed a large 7-story fireproof building, to be used for general manufacturing purposes, and are now at work on a new 60x600 ft. foundry building, which it is expected will be ready for occupancy by Jan. 1. These improvements will necessitate the employment of 100 additional iron moulders, 70 brass moulders and 500 extra help in general manufacturing.

The Field Force Pump Co. is occupying a new plant at Elmira, N. Y., which includes a 57x118-ft. foundry, 43x120-ft. machine shop, 50x58-ft. woodworking shop, 24x58-ft. paint shop, 46x58-ft. shipping room, 40x60-ft. storehouse, and several smaller buildings.

Perrin, Seamans & Co., Boston, Mass., have recently secured orders for a number of their new-style stiff-legged derricks, both hand and steam power. This firm is now issuing circulars describing these derricks, which may be had upon application to them.

THE ENGINEERING RECORD.

Volume XLVI., Number 21.

TABLE OF LEADING ARTICLES.

Advice to Young Engineers.... 481
Subordinate Engineering Positions in New York Departments 481
A New Reservoir at New London, Conn. (Illustrated) 482
The Maignen Preliminary Filters for the Preparation of Water for Sand Filtration.... 484
The Hibernia Building, New Orleans.—I. Foundations. (Illustrated) 486
Comments on Technical Education.... 487
A Slide-Rule for Field Topographic Work. (Illustrated) 489
City Bench Marks in Hartford, Conn. (Illustrated) 490
Economy in the Use of Coal for the Production of Power 491
Extent of Damage to Williamsburg Bridge Cables 492
The Control of Non-Navigable Streams by the National Government 492
Residential Septic Tanks.... 494
Sea Mills Sewage Disposal Works, near Bristol, England 495
Computation of the Stability of High Chimneys.. 495
Ventilation in the Pratt Institute High School, Brooklyn. (Illustrated) 495
The Circular Dam at Lake Cochituate. (Illustrated) 497

The Engineering Record is published every Saturday at 21 Park Row, New York. Its opinions on technical subjects are either prepared or revised by specialists.

Subscriptions are received and single copies supplied by the International News Company, Breams Building, Chancery Lane, London.

The subscription rate is $5 a year for the United States, Canada and Mexico, and $6 for other countries in the Postal Union. Remittances should be made by check, New York draft or money order in favor of The Engineering Record. No responsibility is assumed for payments made otherwise, except those for subscriptions to the International News Company.

Advice to Young Engineers.

It is commonly said that it costs nothing to give advice, but when a busy consulting engineer will give up the greater part of a week for the purpose of addressing a body of young men it does not need exceptional wisdom to realize that the advice costs a considerable sum to the giver. And when an extended and varied practice is drawn upon to furnish illustrations of the speaker's main topics, there is apt to be a number of points of general interest in the remarks, although addressed primarily to engineers in the embryo. This is certainly true of an address which Mr. J. A. L. Waddell delivered before the last graduating class of the Rose Polytechnic Institute. Not the least interesting feature about it is the clear statement of a few views concerning current engineering practice which The Engineering Record considers just as misleading as they are interesting.

As an example of what is meant by misleading views a single quotation may be made from the portion of the address on the desirability of different specialties. "Believe me," the speaker stated, "I would prefer a position as boss-grader on a dump to that of city engineer, and I would rather work as a navvy with a pick and shovel than accept a subordinate position in the engineering department of a city." It may be safely stated that most members of the profession would select the duties of city engineer to the job of boss-grader, and it is hard to believe that many assistant city engineers will seize the first opportunity to resign for the honor of doing day labor in a trench. In fact, it is questionable whether the speaker's own feelings might not experience a change were he actually confronted with the necessity of making a choice.

Such disparagement of the very important field of municipal engineering is particularly unfortunate because to-day there is a greater demand for young graduates for this class of work than for any other. The consulting specialists in municipal engineering are men of as high standing in the profession as those whose work is along railway or structural lines. The salaried engineers engaged in municipal engineering are probably as well paid and as well treated as men on salaries in other engineering specialties, while they certainly average fewer hours of work per week. Moreover the public appreciation of the value of good municipal engineering is growing by leaps and bounds, as taxpayers learn that a competent city engineering department will earn many times its expense—even when paid very liberally—by saving their money from both useless waste and costly parsimony.

The great objection to municipal work has been an alleged insecurity of the tenure of office. "It degrades a man, in his own estimation at least," Mr. Waddell told his hearers, "to feel that he is at the mercy of every log-rolling, wire-pulling ward-politician, who may for any reason take offence against him." This is only true in a limited sense. It degrades no man to know that he is unpopular with vicious persons, but it by no means follows that a log-rolling, wire-pulling ward-politician is vicious. Many men who are eminently successful political managers are working with only the public welfare in view, and many men who have the name of being political hogs are really public benefactors. Everyone poses as a judge of public affairs, yet very few have any qualifications for forming a reliable judgment. Politics is a hobby with many people of the highest character, yet the acts of such men are criticized by their fellow citizens with a savageness which a reputable judge would not use to a convicted criminal. Municipal work of all classes has come to have a bad name that it does not deserve, and while too many changes are made in municipal offices for other causes than the public good, it is but fair to point out that in other branches of engineering, tact, a good presence, business ability and family influence are often more important than strictly engineering qualifications.

Another statement in this address which is misleading was the following: "The services of a newly-fledged engineer are, as a rule, of little or no account." This is literally true in some cases, yet the implication that technical education is not of much value in practical engineering is very far from the case. In fact, Mr. Waddell, practically denied the statement a little later in the same address by mentioning that fair salaries can be obtained by young graduates in a number of lines of work. What he really meant is better indicated by another quotation: "In our office we figure that it takes three months to bring the value of the recent graduate's services up to zero, and three months more to recoup the office for its loss on his instruction; so it is not until after six months his work really begins to become remunerative." This last quotation is what might be expected by anyone familiar with the character of the work that is done in the speaker's offices; and the fact that it takes six months to train a graduate to the work of this office does not mean that, without such training, the young graduate's business value is nil. It simply means that the requirements of that particular office are so special that it takes time to learn to meet them.

It is just the same in any business, and the fact that the man to be trained is a young fellow with only a technical school training has nothing to do with the principle involved. It is unfortunate, therefore, that just at a time when the most encouragement should be given such young men, their ambition receives a chilling blow of this sort. The nature of young graduates is the same as that of older men; some of them dream vain things and to others a spade is always a spade. Some are willing to step from the school into the office of chief engineer of any old thing, but how many of us with gray hair are without a half-dormant consciousness that we could, for instance, have settled the anthracite coal strike with celerity and equity had we only possessed the power? Every business has its special features, and every house in that business has its special practices, and the most experienced man could not pass from one house to another without spending some time in becoming acquainted with his surroundings. In passing from one business to another, more time is needed. In the same way, in passing from a technical school to an engineering office, a young man makes a purely business change and his employer must expect to be at some expense while the ropes are being learned.

It must not be thought that because The Engineering Record cannot agree with some of Mr. Waddell's views that his address did not contain advice of much value. Many portions were excellent, for example: "In dealing with people, a cultivation of policy and tact is a virtue. Because you think a man is a fool, that is no reason for telling him so. When you see that an individual is cherishing some set notion which is erroneous, it is far better to lead him gently to a recognition of his error than to tell him imperiously that he is wrong or does not understand the matter." Probably no piece of advice to young engineers can equal this in value. The professional duties of the engineer are concerned with applied science; with utilizing natural laws and material substances. But success is impossible without something more than knowledge and skill in applying it. Success can only come with the ability to delegate work to others, each receiving that best suited to his attainments, and ability to convince busy men without technical knowledge of the importance of the engineer's advice. The successful engineer must understand how to handle men as well as to apply science.

Subordinate Engineering Positions in New York Departments.

Recent statements in several New York newspapers indicate that it has been impossible for some city departments to obtain as many transitmen and topographical draftsmen as are needed to carry on their engineering work, the salary paid, $1,200 per annum, not being sufficient inducement. When a borough president appeared before the Board of Estimate, which is the guardian of the city treasury, to ask that he be allowed to engage additional draftsmen at a salary of $1,500, it is reported that the Comptroller objected on the ground that the salary at present allowed was greater than transitmen were given by several railroads that he mentioned; notably the Pennsylvania and New York Central roads. Permission was finally obtained to engage a few men at $1,500 per year until January first, when the pay for transitmen is to be fixed at $1,200. It is but fair to the engineering staff of the city to state that the salaries paid by railroad companies and private corporations cannot be directly compared with those paid by a large municipality, especially New York. The transitman in the employment of a railroad company, if he is a capable man, has a greater opportunity for advancement than he would have in the engineering staff of a great city. Furthermore, experience with a private corporation would be apt to have a wider range. Again, the living expenses of a transitman are much greater in New York than they would be on railway work, in which he would be located along the line of the road, much of the time in small communities. Advancement from a transitman's position in the departments of the City of New York is particularly difficult because of the manner in which assistant engineers, the next higher grade, are appointed and the infrequency of these appointments. Many transitmen in the employ of the departments are doing work of an importance that should entitle them to larger compensations than their present salaries, but even these, it seems, are considered to be too large.

In these times of activity the demand for engineering talent is greater than the supply and in the competition to secure this talent, be it that of a transitman or chief engineer, the City of New York can much better afford to pay what is necessary and in other ways make the position more attractive to good men, rather than to let its public works suffer for the want of a proper engineering staff to complete and maintain them.

A New Reservoir at New London, Conn.

The water-works of the city of New London, Conn., are at present being extended under the direction of W. H. Richards, engineer, so that the supply will be practically doubled. The reservoir which will be the means of effecting this addition will soon be completed and presents a number of interesting features. The reservoir is formed by an earth dam approximately 1,200 feet long with a concrete core wall, and a supplementary dam about 400 feet long, entirely separate from the main structure, was necessary at one end. The height of the main dam above the natural surface does not much exceed 20 feet, but at the center of the structure a fine, wet sand was struck which made it necessary to sink the foundations much deeper than had been anticipated—a total of about 62 feet below the surface at the deepest part. At the upper end of the reservoir a so-called filter dam has been constructed across the main brook, through which the water will percolate from a section of the reservoir which it was deemed inadvisable to strip as thoroughly as the main basin.

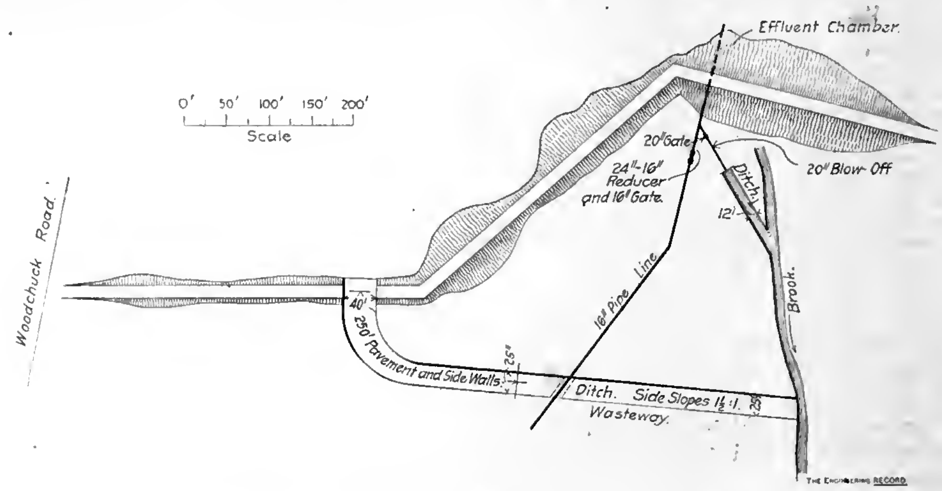
The principal water supply of the city has, up to the present time, been drawn from a body of water known as Konomoc Lake, about six or seven miles from the city, which furnishes about one and one-half million gallons per day. The surface of the original pond was raised by means of a dam so that its total capacity is now between six hundred and six hundred and fifty million gallons. The water from this lake passes to the city through two mains, 20 and 16 inches in diameter. As there is both a high service and a low service the draft of water for the latter is utilized to raise the quantity required for the high service to a tower in the higher portion of the city. The supply from Konomoc Lake having become inadequate for the needs of the city, it became necessary to obtain a further supply at once.

The new supply, which it is estimated will also furnish one and one-half million gallons of water daily, is drawn from a watershed of about 2 square miles area just beyond the old one, and the two reservoirs are connected by a 16 and 20-inch pipe line, a branch being left for connection with a proposed third reservoir when needed. The distance between the new dam and the head of Konomoc Lake is about 3 miles, making the former about 10½ miles from the city. It should be stated that the arm of Konomoc Lake nearest the new reservoir, while of considerable area, is shallow and marshy, and this portion is cut off from the main body of the lake by a filter dam or embankment of coarse gravel. This simple expedient is very effective in decolorizing the water, the difference on the two sides of this embankment being at times very marked. The new supply will all pass through the old reservoir, and it is proposed to build that part of the connection which passes through the old watershed in the form of an open channel so as to intercept a large part of the water which now flows into the shallow arm of the reservoir just mentioned.

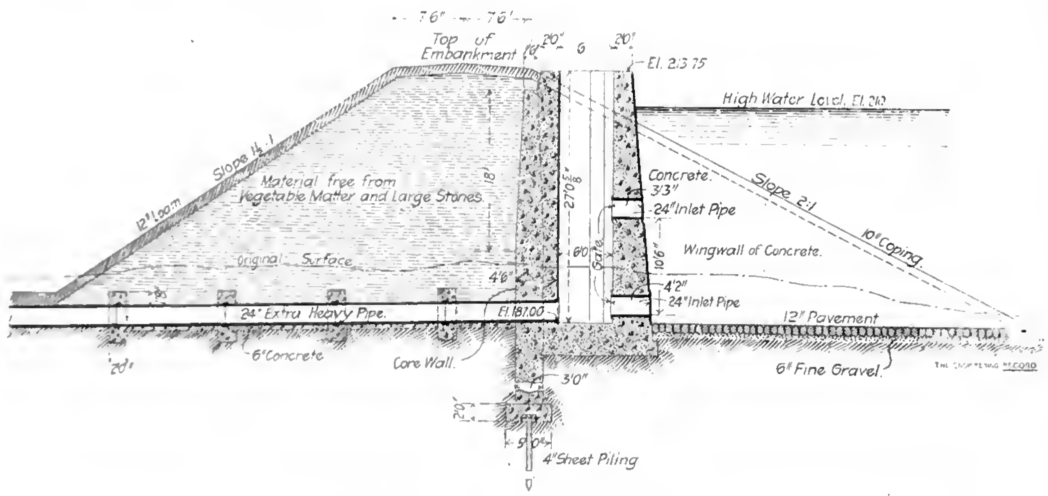
The new dam is irregular in plan, this arrangement having been chosen in order to utilize several natural mounds in the valley, which, while making the excavation for the core wall deeper in places, reduced the amount of necessary embankment. In making the preliminary studies, test pits were sunk along the line of the proposed dam, and these seemed to show that a fairly good foundation for the core wall would be reached at a reasonable depth. The soil of the whole region is of a gravelly nature, so much so that it was impossible to obtain any clay for puddle in the dam. Underlying the superficial gravel formation in the valley is a layer of hard, compact clayey gravel containing some boulders, and it was supposed from the indications of the test pits that this layer was at a fairly uniform depth across the valley. This, however, proved not to be the case, for near the center of the dam a pocket of fine running sand was struck, which, at the deepest part, was about 30 feet wide and extended to a depth of 62 feet below the surface. Although not exactly what would be called a quicksand, it was necessary to confine this material very carefully in order to carry on the work. On one side of this pocket the hardpan rose almost perpendicularly to within 19 feet of the surface, but on the other side it rose to about 44 feet from the surface and then sloped fairly regularly for 275 feet to a point where it was 35 feet from the surface and rose abruptly.

This unexpected condition of the foundation added greatly to the difficulties and cost of construction. The sides of the trench for the core wall had to be protected with sheeting and carefully timbered. In the bottom of the trench, for a distance of about 400 feet, 4-inch matched and splined sheet piling was driven down to hard bottom. This was a rather delicate operation on account of the material encountered and the depth of the trench, and it was found that comparatively light blows on the piling gave the best results. The maximum depth of trench was 40 feet below the surface and the piling was driven 22 feet below this. At first an ordinary rock drill with a 20-pound weight in place of the drill was used to drive the piles, and, as far as the driving was concerned, it gave good satisfaction. The rapidity of the blows gave the pile no time to stop or jump back, and it was driven as though by a steady pressure. However, as the drill had not been designed for such a purpose as this there were several breakdowns, and an ordinary pile driver was finally used. This was operated so as to give very light blows, it being found that otherwise there was a tendency to disturb the sheeting on either side of the trench. A 1,700-pound hammer was used, with a fall not exceeding 5 feet. A couple of heavy wale pieces were bolted along the top of the sheeting and the footing course of the concrete core wall was laid around them.

The core wall is 3 feet thick at the base and 1½ feet at the top. The specifications called for a concrete of 1 part cement, 3 of sand, 2 of fine gravel and 4 of stone not larger than 2½ inches. It was found that in several places on the work a sandy gravel could be obtained without screening, which answered this description very closely and uniformly, so that all that was necessary was to mix the one part of cement with nine parts of this gravel, care being taken of course to remove all large stones. Nazareth Portland cement was used for



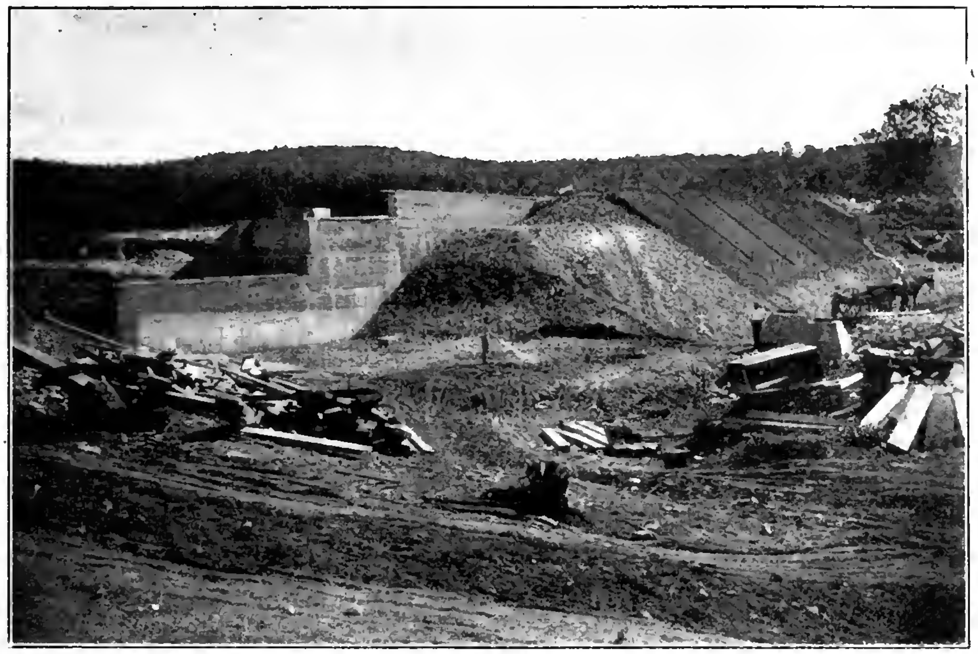
PLAN OF MAIN PART OF DAM, NEW LONDON, CONN.



SECTION THROUGH EFFLUENT CHAMBER.

most of the work, although Atlas was used to some extent. The concrete was mixed so wet that no tamping was required to consolidate it. The water face of the core wall was plastered with ½-inch of one to one mortar and brushed over with a cement wash.

The results seemed to bear out the expectation that in spite of the thinness of the wall it will be practically water-tight. The concrete presented a solid, compact appearance, entirely free from the voids which might, perhaps, have been expected from such a lean mixture. The forms were made of ordinary rough planking and the large cracks



Down-Stream Face of Dam at Effluent Chamber.

and knot-holes were plugged up inside with mortar before the concrete was laid, so as to prevent the mortar of the concrete from running out of the cracks. In order to thoroughly bond new work to that already laid, short lengths of timber were half buried longitudinally in the top and end of a section as it was finished, thus making recesses when the blocks were removed.

The effluent gate chamber, about 6 feet square inside, is also built of concrete, but for this work large boulders were placed in the walls, care being taken that they did not come too near the surface. There are two 24-inch sluice gates opening into this chamber, 10½ feet apart vertically. The wing walls of the approach to the effluent chamber are entirely of concrete and are perpendicular to the center line of the dam. A small gate house will surmount the effluent chamber, and its walls of rough cobbles will be in keeping with the wildness of the surrounding country.

The bottom of the gate chamber is 9 feet above the level of the water in the old reservoir, which determines the minimum head for the three miles of pipe line connecting the two. There is a [illegible]-inch pipe line for about a third of the way and a 20-inch line the remainder. At the lowest point it is 50 feet below the level of the old reservoir. It has been estimated that with a head of 15 feet above the old reservoir, or 6 feet above the bottom of the gate chamber, the discharge will be one and one-half million gallons per 24 hours. The level of high water in the new reservoir will be 32 feet above that in the old one, or 210 feet above tide water at New London.

As it was found impossible to get any clay for the water side of the embankment, selected loam was used. It was placed in 6-inch layers and thoroughly rolled, and it is thought that the result will be in every way satisfactory. The water face of the dam is paved with 12-inch cobble-stones on 6 inches of sand, and the finished work presents a very smooth and compact appearance. There were about 4,200 yards of this paving. The accompanying photographs show the two sides of the dam near the gate chamber as they appeared early in August, when nearing completion.

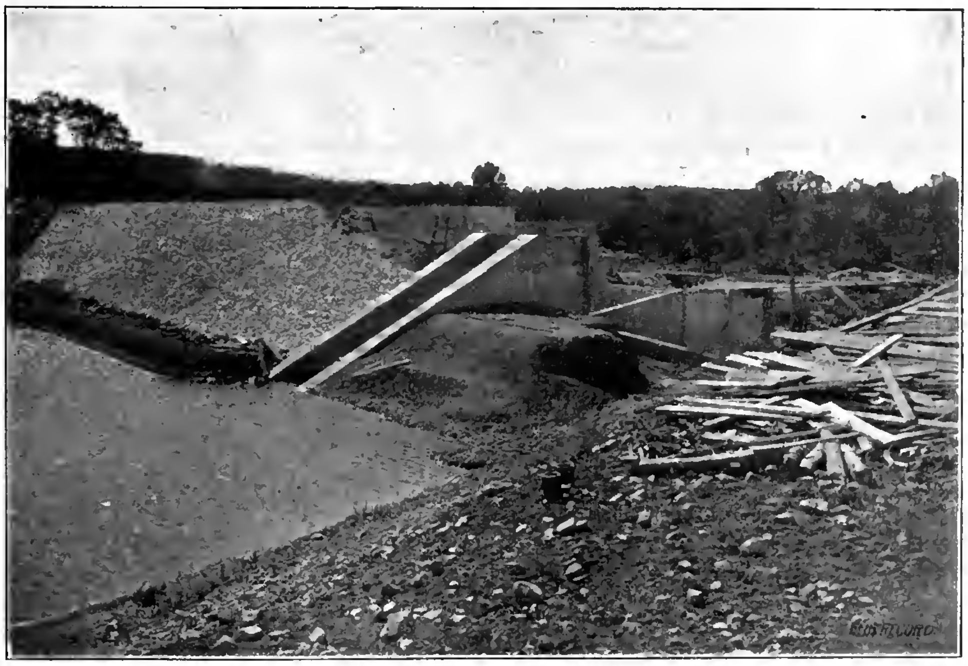
The portion of the embankment on the down-stream side of the core wall was made, according to specifications, of material free from vegetable matter and large stones, thoroughly watered as deposited. This was almost entirely gravel. In addition to the watering it was further compacted by the passing of teams over it. It will be observed from the section that the core wall was placed well toward the water face of the dam. This was done in the belief that the impervious part of the dam should be placed as near the water face as possible, consistent with stability, and that the gravel filling behind the core wall gives the necessary weight. The down-stream face of the dam is to be grassed over.

The spillway is 40 feet wide and is built of rubble stone masonry, with a coping course of dressed stone. In passing over this spillway, the water will fall about 3 feet vertically and then flow down a wasteway with a slope of 12 in 100, about 250 feet long, with dry rubble side walls and a paving of 15-inch cobbles placed on end. In planning this wasteway, the natural slope of the land was utilized so as to necessitate as little filling and excavation as possible.

One portion of the reservoir site was covered with hardwood timber before the work began, and this was utilized for fuel, both for domestic purposes and for making steam. In the bed of the reservoir proper all top soil, muck and roots were grubbed out, leaving, as far as practicable, a clean gravel surface. Some 17,500 yards of this material was removed. Above the filter dam the surface was only cleared off, not grubbed; and in some parts of the reservoir bottom a layer of gravel was placed over the natural surface after removing large roots and stumps.

The filter dam just mentioned is about 400 feet long, 10 feet wide on top and 20 feet high, with side slopes of 2 to 1. It is composed entirely of gravel. There is a 24-inch pipe through the bottom of this dam, through which the brook has flowed during construction. An overflow is arranged so that when the water reaches a certain level it will flow directly into the main body of the reservoir. It is estimated that the capacity of the reservoir will be one hundred and seventy-five million gallons. It will cover 50 acres and have an average depth of 20 feet.

The new reservoir is located practically in the wilderness, there being but two buildings of any kind on the whole watershed, and all the materials had to be carted over 10½ miles of hilly road in very poor condition, from New



Up-Stream Face of Dam at Effluent Chamber.

London. The carting of 3,500 barrels of cement over this road was by no means a small item. A telephone line was built to give ready communication with the city. The work done included about 28,000 cubic yards of embankment and 3,700 cubic yards of concrete. The original contractors threw up the work after it was begun, and The C. H. Eglee Company, of Boston, has performed nearly the whole of the contract. The assistant engineer who has had direct supervision of construction is Mr. Robert W. Chaffee. The cost of the completed reservoir will probably be about $80,000.

The Maignen Preliminary Filters for the Preparation of Water for Sand Filtration.

The rate, and consequently the cost, of operating a sand filter, as well as the quality of its effluent, are materially influenced by the nature of the applied water. The method heretofore commonly in vogue for preparing turbid or muddy waters for filtration has been subsidence for a longer or shorter period in settling basins, with or without the addition of coagulants. Another scheme has been suggested within the last few years by Mr. P. A. Maignen and has been made the subject of experimental research in Philadelphia. Instead of using a settling basin, a device known as a scrubber is used for removing a considerable portion of the turbidity from raw river water before applying it to the surface of the sand filters. At the same time, a scrubber also removes a large percentage of the bacteria. The Maignen Filtration Company is to erect a number of these scrubbers, or preliminary filters, at the Lower Roxborough filtration station of the Philadelphia water-works. The description of the scrubbers and the discussion of their efficiency and economy given below have been condensed from a report made by Messrs. Rudolph Hering and George W. Fuller, of New York, to the Maignen Filtration Company. This report is based on experiments conducted at two stations in Philadelphia, one supplied with Schuylkill River water after settling for several days in East Park Reservoir, and the other supplied with raw water as pumped from the same river.

The Maignen system in general consists of the double filtration of water, two or more kinds of filtering materials being used in each filter. The first filtration takes place at a rapid rate in an upward direction through coarse-grained material, like broken stone, coke or slag, supplemented at the top by a layer of "elastic material," such as sponge or peaty fiber. In these preliminary filters the rate of filtration is nominally sixty million gallons per acre daily. In the event that for long periods at a time the raw water should be very turbid, consideration would be given to "scrubbing" the water more than once, or to some other preparatory treatment preceding the regular scrubber. Scrubbers are cleaned by occasionally reversing the flow of water through them, and less frequently by removing the materials, cleaning and replacing them.

The following advantages are claimed: Scrubbers are much cheaper to install, per unit of water treated, than subsiding reservoirs; are especially well adapted for sites where land is very limited in extent and expensive, because of the relatively small area required per unit of capacity; and are capable of preparing river water for filtration without the use of coagulants up to higher limits of turbidity in the raw water than are ordinary settling basins. Scrubbers are capable of giving more thorough clarification to ordinary water than it is possible to obtain by subsidence. The smaller amount of turbidity in the water, when leaving the scrubbers, as compared with that leaving the subsiding basins, causes a considerable reduction in the cost of operating the final filters, and so the scrubbers are to be credited with the saving in filter charges. Scrubbers can be cleaned economically, and in total cost are cheaper for the preparatory treatment of moderately turbid river water than plain subsiding reservoirs.

When a scrubber is operated under reasonably favorable conditions, it is very noticeable that it yields a water for final filtration which contains only very little turbidity, and which is much clearer than that obtained by means of sedimentation, for, say, one to three days. The scrubber effluent is, also, purer from a bacterial standpoint, as the percentage removal of bacteria in the river water by sedimentation and by scrubbing is about 40 and 80, respectively, on an average. Thus the purity of the scrubber effluent would be three times as great as that of the settled water. In other words, it would require, on this basis, a removal of 60 per cent. of the bacteria in the settled water to yield a product equal in quality to that of the scrubber effluent.

In a number of places it has been found that when a water has been filtered once, under ordinary conditions as to rate and materials of filtration, a second filtration is sometimes of very little or no benefit. The reason assigned for this experience is that the first filtration removes those constituents which are necessary in order to "ripen" a filter, through the establishment of gelatinous films around the sand grains, and of certain biological processes. This aspect of the matter has received very careful attention, and the evidence shows that excellent results may be regularly obtained from the filtration of the Philadelphia water after it passed through a scrubber. The construction of the latter and its rate of filtration do not seem to impoverish the local water prejudically as to those constituents needful for developing and maintaining the final filter in a well-ripened and efficient condition.

Experience shows that as a general proposition the cost of operating large gravity filter plants is proportional to the amount of clogged material removed per unit volume of water treated. This statement assumes, of course, comparable conditions as to facilities and wages of laborers, and disregards such special features as removal of ice from open filters. The cost of executive and laboratory control is also excluded, as this is not directly related to the character of the water after it has been prepared for final filtration.

Experience at several places also shows that, approximately speaking, the amount of clogged material to be removed from filters, other things being equal, is proportional to the turbidity (within ordinary limits) of the applied water. At many, and perhaps most, filter plants, this principle is not readily apparent from the records, because there are not obtained continuous periods of sufficient length to show what can be done with a given narrow range of applied turbidity. Frequently quite a wide range of turbidity is noted during a single run between clearings, and occasionally a larger yield is obtained with a high than with a low average turbidity. These are largely explained by differences in the condition of the sand layer at the beginning of the run. Where raw water is applied to filters, complications also arise in some instances from algae growths and suspended organic (amorphous) matter, which clogs a filter to an excessive degree in proportion to its turbidity. Notwithstanding the obscuring of data by a variety of causes in practice, this principle is a correct one. From the foregoing it follows that the cost of filter operation is approximately proportional to the turbidity of the applied water, and upon this principle rests one of the principal merits of the scrubber.

Available evidence indicates that settled water at Philadelphia would average about 20 parts of turbidity per million. With filters operated at a six million rate and a 4-foot loss of head, the yields between cleanings would probably average about seventy million gallons per acre, and the average depth of scraping about ¾ inch. This makes the amount of clogged material to be handled about 1.5 cubic yards per million gallons of water filtered. The average turbidity of a scrubber effluent would probably be between 5 and 10 parts, so that there is every reason to believe that the average filter yield between cleanings would be about twice as great as with settled water, other things being equal. Hence it is concluded that a scrubber effluent as compared with settled water would reduce the cost of filter operation by about 50 per cent. Furthermore, from the evidence presented up to this time it is to be gathered that a scrubber could give additional stability to a system of purification in which a high rate of filtration is employed; and, therefore, it is entitled to certain financial credit by making feasible these relatively high rates of filtration.

The term "muddy water" is a relative one, and conveys different impressions according to the associated conditions. For present purposes in discussing the local river waters we may draw the line between muddy and non-muddy water at about 75 parts of turbidity. Of course, this limit represents a water which is far from clear, as in it one could see a pin in bright daylight only through a depth of about three inches. This purely arbitrary method of classifying the local river waters is based on the evidence that when such water is given an ordinary preparatory treatment by settling or scrubbing, it can be purified by properly constructed and operated filters of the slow type satisfactorily as to appearance and bacterial removal. To be sure, the lower the turbidity, the cheaper and safer will be the filtration, as already stated, but the point here made is that with this limit the turbidity of itself does not preclude obtaining a filtered water of high grade.

Between the limits of about 75 and 200 parts of turbidity in the river water, preparatory treatments such as here considered permit a filter ordinarily to be operated so as to yield for some days a water of satisfactory bacterial quality, but of an appearance somewhat opalescent, or cloudy. So far as known, such turbidities in the filtered water, due to fine clay particles, are not prejudicial to health. With these limits of turbidity the frequency and cost of cleaning the filter are of course materially increased. Beyond about 200 parts of turbidity in the river water, the influence of this factor in connection with the processes here considered becomes more marked if continued for a number of successive days. When such turbidities prevail for one or two weeks, it is likely that the filtered water might contain so many clay particles that the consumers would call it muddy. Under such circumstances the functions of the filters become more or less deranged, and it is possible that there would be interference with the ordinary capacity for bacterial removal.

On the turbidity basis of 75 parts per million, the Delaware is "not muddy" for about 90 per cent. of the time and the Schuylkill for 85 per cent. These figures are obtained by excluding those periods when for two or more days at a time the turbidity was 75 parts or more. The limit of 200 parts turbidity is not reached in the Delaware during more than 96 per cent. of the time and in the Schuylkill 94 per cent. With regard to the character of the turbidity of these two river waters, it is to be said that the suspended particles are very fine in character. This is shown both by the behavior of the water in settling basins and in filters, and also analytically. The turbidity coefficient, that is, the ratio between the silica turbidity and the weight of the suspended matter, 0.60, is unusually low, as judged by the general information now available upon this subject.

The Schuylkill River water adds a possible complication to its treatment by reason of the coal dust or culm which it contains from time to time. While this factor is a decided detriment to the character of the raw water if used without further treament for a public supply, it does not seem to add serious complication to processes for complete clarification and purification, because the culm is less difficult to remove than the large quantities of exceedingly minute clay particles which are suspended during heavy floods.

When water approaches quiescence the matters suspended in it are to a greater or lesser degree deposited. The rate of deposition depends upon the remaining velocity of the water in connection with the subsiding value of the suspended particles. Velocities are affected by relative temperatures of water and air, and by the degree of baffling which exists in a basin to prevent water from passing from the inlet to outlet, and thus putting a portion of the basin out of service, practically speaking.

General experience indicates that as a rule it is not economical or advisable to continue plain sedimentation in water purification works to more than about 24 hours. Exceptions of course are to be found where this factor has to be considered with reference to other portions of some works. Where river water receives occasional treatment with coagulants, and is later applied to filters of the slow type, experience shows that after coagulation the water should be settled for at least 24 hours. This is necessary in order to remove the coagulated matters so that they will not accumulate at the surface of the sand layer and quickly clog the filter. Taking everything into consideration, it may be concluded that where settling reservoirs are still unbuilt it would be advisable to build basins holding about 24 hours' flow. With plain sedimentation it is estimated that the removal of turbidity and bacteria would average about 30 and 40 per cent., respectively. As it is the heavier particles which subside, the removal of suspended matter would be greater than the turbidity removal.

On the preparation of Philadelphia water by means of scrubbers, on the other hand, the following observations may be made:

Filtration should take place in an upward direction, at a rate not exceeding 100,000,000 gallons per acre daily. Sudden fluctuations should be avoided. The net yield is estimated at 60,000,000 gallons per acre daily. As to the materials in the Maignen scrubber it has been found that the original device may be improved somewhat by placing one or two feet of finer material between the elastic layer and the necessary bottom layers. The elastic layer should be about eight inches in thickness, suitably compressed. Piping connections need no comment, except to state that, for purposes of frequent cleaning by reverse flow of water, sewer connections should be provided. In order to remove readily the dirty wash water and the air in the pores of the pebbles upon refilling, it is well to have outlet pipes just below the elastic layer.

Regarding the best kind of elastic layer to use, it has been found that sponge clippings are somewhat more efficient than peaty fiber. So far as can be ascertained, there is available a sufficient quantity of sponge clippings to serve all needs in view. Should prices become excessive for this commodity, peat or similar material might be substituted temporarily. As to the life of sponge clippings in a scrubber, there is no evidence of chemical decomposition, owing to the mineral nature of the product. There is some physical disintegration during washing. Although some sponge is disintegrated in washing, it appears that the smaller pieces can be used for some time. At each washing it is estimated that the net loss of sponge would average not over 2.5 per cent., and probably considerably less than this.

The conclusions as to the efficiency of scrubbers in removing turbidity on a strictly physical basis are as follows:

The work of scrubbers, in treating a water having a fairly wide range of turbidity, is characterized by effecting a certain percentage removal, and not by maintaining a fairly constant turbidity of the scrubbed water regardless of the applied. The percentage removal ranges under different conditions from about 35 to 90; ordinarily the range is from about 50 to 80, and the average which might be expected in practice is in the vicinity of 65. When the local water becomes more turbid than is ordinarily the case, the percentage removal is somewhat more liable to fall below than above the average.

As to the removal of bacteria, the percentage seems to be rather higher than for turbidity. The average is estimated at 80 per cent. A scrubber does its best work when the applied water has a turbidity of 50 parts or somewhat less. When a turbidity of more than about 75 parts is applied, it begins to fail somewhat in its purpose when working on a strictly physical basis. In the case of scrubbers dealing with excessively muddy water, normal operations can be maintained only by giving to the water a preliminary treatment. Should such treatment involve coagulation, it would be necessary to provide settling capacity of about six hours' flow in order not to overtax the scrubber.

Regarding the operating charges, it is estimated that 1 per cent. of the water would be used for cleaning by occasionally reversing the flow. This figure seems very liberal, and it is quite likely that a part of this charge could be applied to better advantage to "working over" and rearranging the sponge layer. When receiving a water which they could properly treat, it is estimated from the available evidence that the scrubbers would yield on an average about 6,000,000,000 gallons per acre, with a maximum loss of head or about 2.5 feet, between the periods of removing the sponge layer washing and replacing it. At the stated rate this means about four sponge cleanings a year. It is further estimated that the granular material would have to be washed about once a year, in addition to flushing whenever the sponge layer is cleaned. A moving platform would be provided above the space between the scrubbers, upon which the sponge could be washed in a machine operated by electric or hydraulic power.

The available evidence indicates that the average removal of turbidity from the local river waters by settling basins (24 hours' capacity) and scrubbers would approximate about 30 and 65 per cent., respectively, and of bacteria, 40 and 80 per cent., respectively. As to the residual turbidity of the treated water, during all ordinary conditions in the river, it is estimated that it would be about 20 and 10 parts, respectively. The probabilities are that a scrubber effluent is much more likely to average less than 10 parts than is a settling basin less than 20 parts. During muddy water the scrubber effluent would be about one-half as turbid as a settling basin effluent, should both be operated on a strictly physical basis. Should both receive special preparatory treatment, the results would be kept approximately within the general averages above stated.

Concerning the cost factors, there are two aspects of this case. One refers to the items which can be estimated quite closely, and the other is less definite, dealing with the question of higher rates of filtration which are permitted by the better preparation afforded by the scrubber. As stated, this item throws the advantage decidedly in favor of the scrubber, were all other factors a tie.

The final conclusions are that where settling reservoirs already exist, scrubbers will reduce the cost of operating the final filters sufficiently to save their own total cost, in addition to the saving effected by the smaller area of the filters; and where settling reservoirs are not yet built, scrubbers will effect a saving in addition to the saving effected by the smaller area of the filters.

Typhoid Fever and a Pure Water Supply do not naturally go together. A striking illustration of this was mentioned by Mr. P. Byrne in a paper presented to the Engineering Association of the South last June. The supply of a Mississippi town of 1,200 inhabitants was obtained from surface wells. During a canvass for and against water-works, one August, there were 64 cases of typhoid. The advocates of the water-works won, and the system was constructed a few months later. In August of the next year there was not a case of typhoid fever within the corporate limits.

The Re-inspection of all Water Fixtures in the city of Philadelphia, begun by directions from Mayor Ashbridge, is summarized as follows in the 1901 report of Wm. C. Haddock, director of the Department of Public Works: The total number of inspections amounted to 248,226, and 40,418 properties were discovered having appliances for which no water rents were being paid. The total number of delinquent appliances revealed by the inspection was 70,660. The water rent chargeable to these fixtures amounted to $146,057. The cost of the inspection was $26,448, showing a net revenue to the city of $119,609. Each succeeding year the city will gain the gross amount.

The New England Water-Works Association held the first of its winter meetings at Hotel Brunswick, Boston, on November 12. There was a good attendance. The following persons were elected to membership in the Association: Robert E. Horton, hydraulic engineer, Utica, N. Y.; John W. Alvord, consulting engineer, Chicago, Ill.; George A. Sanborn, superintendent, Essex Company, Lawrence, Mass.; Harry E. Barnard, chemist to New Hampshire State Board of Health, Concord, N. H.; D. A. Heffernan, superintendent of Water Works, Milton, Mass.; David Dexter Clarke, engineer to Water Commissioner, Portland, Ore.; J. H. Ince, assistant to president, Western New York Water Company, Buffalo, N. Y.; William P. Conard, Burlington, N. J., and R. O. Wynne-Roberts, engineer of Water Works, Capetown, South Africa.

The following members were appointed by President Frank E. Merrill to serve as a "Committee on Private Fire Protection:" F. H. Crandall, Burlington, Vt., R. J. Thomas, Lowell, Mass., and Elbert Wheeler, Boston, Mass. A communication was read from Mr. Alphonse Fteley, expressing his appreciation of the honor conferred upon him by the action of the Association at its September meeting in electing him to honorary membership. A paper on "Economy in the Use of Coal for the Production of Power" was read by Prof. Ira N. Hollis, of Harvard University, and a paper entitled "Waste Heat Engines" was presented by Prof. Edward F. Miller, of the Massachusetts Institute of Technology. We regret that in a previous issue it was erroneously stated that the election of officers would take place at this meeting. The report of the nominating committee was made public, but additional nominations will be received up to December first. The official ballot will be sent out about the middle of December and the vote will be canvassed at the annual meeting, in January.

The Hibernia Building, New Orleans.—I. Foundations.

The new Hibernia building, adjacent to the St. Charles hotel, at Carondelet and Gravier Streets, New Orleans, La., is an 82x128-foot steel cage structure with a basement, twelve stories and an attic, rising to a height of about 200 feet above the pavement. Messrs. D. H. Burnham & Company, Chicago, are the architects and Mr. J. G. Glaver is the structural engineer. The 2,000-ton framework has 34 steel columns arranged in four longitudinal and seven transverse rows, which, with the beams and girders, are designed in conformity with the steel office building construction in northern cities, which has been frequently described in The Engineering Record. There are some special features in the detailing of the steel work of the superstructure, but the principal ones are in the foundation, which is built on very wet, soft ground and carries a much taller and heavier structure than many others in the vicinity, which have settled seriously. In this building any serious distortion would be detrimental to the masonry fronts, and great care has been taken to avoid its occurrence. It is not expected to absolutely prevent settlement, but it will be limited to a small amount, and that amount is expected to be regular so as not to cause any relative displacement or dislocation of different parts of the building.

The soil is the natural, sedimentary deposit of the Mississippi delta, is very fine and soft, and saturated with water to within about 3 feet of the surface. Ordinary buildings which have loads of not more than 1,500 pounds per square foot on their foundations a few feet below the surface have, in many cases, settled deeply and irregularly and a foundation load of 1,000 pounds on the surface of the soil is considered as much as is desirable. The column footings in the Hibernia building are each supported on a group of from 16 to 36 15-inch piles driven about 30 inches apart and loaded to a maximum of about 30,000 pounds each. These piles are about 50 feet long, have square ends and are driven by a 5-ton steam hammer. The retaining walls are carried on piles which have much smaller loads. All piles are cut off below water level, from 6½ to 13 feet below the basement floor. In each column footing the piles are driven in even or staggered rows in a rectangular area, and have their heads cut off in the same horizontal plane. The earth is excavated 1 foot below the pile tops, and concrete is rammed in around the tops to a height of 18 inches above them and to a distance of 6 inches beyond the outer rows.

The top of the concrete is covered with a grillage of steel I-beams set close together, and the concrete is built up to a level of 4 inches above their upper flanges so as to enclose them on all sides. The grillage beams are 9, 10, 12 and 15 inches high according to their lengths, which vary from 6½ to 15 feet. Those for the heaviest interior columns have 18 15-inch 40-pound I-beams 14 feet long on a footing 15 feet square and receive their column load through five 20-inch 95-pound I-beams 14 feet long seated across them at right angles on the center line of the pier. The other grillages have similar distributing girders which vary from 15 to 24 inches in depth and receive at their center points the cast-iron column bases. In all cases the tops of the bases are set below the basement or first floor level, and the concrete is carried up continuously from the tops of the grillages with a sufficient width and thickness to enclose them and the distributing girders and the joint between the foot of the column and its base.

Only about 50 per cent. of the area of the lot is excavated for the basement and this feature brings the retaining wall well within the lot line. Correspondingly, the foundations for nearly all the wall columns are carried up to a level several feet above those of the interior columns and no more excavation was made around them than was necessary for their construction, after which the earth was back filled around them up to the first floor level, as shown in the vertical sections of the substructure. The retaining wall carries the ends of the first floor beams but does not support any portion of the main walls of the building and has a uniform cross-section throughout, as shown.

Special floor construction in the basement was necessary to resist the upward hydrostatic pressure from the ground water and to prevent its leakage into the basement. This is shown, together with the relative position and arrangement of the wall columns outside the retaining wall and the interior columns inside it, by the general sectional elevation parallel to columns 7, 30, 22 and 23. At the piers the excavation was made 5½ feet below the basement floor level; between them it was made 3 feet below the same level, and 12 inches of broken brick, cinders, etc., were tamped thoroughly over the surface and covered with an 8-inch layer of concrete, a 1-inch sheet of asphalt water-proofing, 6 inches of concrete, another inch of asphalt water-proofing, 7 inches more of concrete and a cement floor finish, one inch thick. This construction interposes a double barrier to the percolation of ground water and a thickness of 21 inches of concrete to resist upward pressure.

The upper water-proofing layer is carried through under the bases of the retaining walls and flashed up outside them on their battered slopes to within 10 inches of the finished first story floor, where it is turned down horizontally and carried between the upper and lower layers of concrete to make a continuous impervious surface enclosing the whole basement below grade. Outside the retaining walls, where the first floor is laid on the earth, it is similar to the basement floor except that it is thinner, with one water-proofing layer and one thickness of concrete omitted. It is built with 7 inches of cinders tamped on the rolled earth, then 6 inches of concrete, one inch of asphalt water-proofing, 8 inches of concrete and a one-inch wood floor nailed to cross strips keyed into the concrete. The water-proofing of the first floor extends under the spandrel wall between piers, and the latter is seated on it on a course of thin full width stones.

Close to the outer walls of the building there is a pipe trench with inside width and height of 3¾ feet and 3 feet. It has a 6-inch concrete bottom at the level of the top flanges of the grillage beams and 9-inch concrete vertical walls and is accessible through a removable cover supported on 3x3-inch transverse T-bars, on top of the side walls, below the basement floor. The asphalt water-proofing is carried around both sides and under the bottom of the pipe trench.

The adjacent buildings on both the inner sides of the lot have, in some places, the same party wall with the Hibernia Building; in other places the position of the light courts makes separate walls necessary. At one point next the St. Charles Hotel where the wall columns are about 38 feet apart, the party wall is carried (up to the second story wall girders which support the upper part of it) on a concrete footing with two rows of staggered piles. At other places in this wall and in the street fronts, the masonry, up to the second story girders is carried on pairs of I-beams spanning the spaces between piers and having their ends supported on the pier grillages. These beams are 8 to 12 inches deep and are completely enclosed in concrete. They have the backfilling well rammed up under their lower flanges, but are assumed to impose no pressure on it, but to carry all loads directly to the main piers across spans of from 4 to 10 feet.

On one side of the lot there is a light court between the Hibernia and the adjacent building and opposite it it was necessary to carry the wall columns outside the retaining wall down to the level of the basement floor. The excavation here was therefore made almost to the maximum depth, and the old adjacent wall was temporarily supported on needle beams while its footings were undermined, new ones built in the bottom of the trench and a concrete foundation wall carried up to the lower side of the old footing to underpin it. After this the space outside the retaining wall was backfilled around the column which, as in other similar cases, was enclosed in a solid rectangular mass of concrete extending from 4 to 6 inches beyond the metal in every direction. At this place the lower story of the spandrel wall is carried on a pair of 12-inch I-beams which are bracketed out from the columns the same as the upper wall girders. Some of the spandrel beams for this wall are, however, carried at one end on the columns and at the other end rest, as previously described, on the grillage beams of columns which have their footings just below the basement floor level.

The smoke stack weighs about 120,000 pounds and has an asbestos lined oval steel shell 4½ feet wide and 7½ feet long. It is seated on a horizontal cast-iron pedestal which has an I-shaped cross-section with top and bottom flanges of unequal width, as shown in the cross-section of the foundation. The pedestal is bedded in the concrete floor with its upper flange just clear of its surface; below it there is a grillage of 6-inch I-beams, 7 feet long, which are carried on two pairs of 8-inch longitudinal I-beams, 9 feet long, set on the center lines of and 18 inches clear of the tops of four piles. This foundation is peculiar in that the cast-iron base does not rest directly on the grillage but is seated on the lower layer of the basement floor concrete which is continuous and here merely acts as a filler above the grillage. The water-proofing course is carried over the lower flange of the cast base and fitted close to its vertical web.

In several places steel tanks are set below the basement floor for sumps, catch-basins, blow-offs, etc. The catch-basin has a steel cylinder 6 feet in diameter and 3 feet deep bedded in concrete and surrounded by the lower layer of water-proofing, as shown in the cross-section. The upper layer of water-proofing is fitted over a special outside flange angle. The tank is lined with 6 inches of concrete on the sides and bottom, contains a concentric cylinder, 3 feet in diameter and 30 inches deep, and is covered by a steel plate flush with the basement floor.

In one corner of the first story there is a massive fire-proof vault with steel and masonry walls, which weighs about 200 tons. It has a foundation about 16½ feet wide and 49 feet long, with nineteen piles arranged in seven transverse rows of three piles each except at one end where they intersect the column piers, and have only two each. The rows of piles are capped with concrete beams 3 feet wide and 5 feet deep and the ends of the caps are connected by similar concrete beams under the side walls of the vault, thus forming a rectangle of concrete 5 feet thick with six open panels 4 feet wide and 8½ feet long. The panels were filled with sand flush with the top of the concrete and on it and the caps was built a solid, continuous floor 23 inches thick, flush with the basement floor. The floor consists of an upper and a lower layer of concrete, 9 and 13 inches thick respectively, with the regular 1-inch layer of asphalt water-proofing between them.

In one corner of the building the footings for three wall columns had to be kept entirely within the lot line which in other places they were permitted to overrun. The columns are accordingly supported on cantilever girders just clear of the under side of the first story floor. The short ends of the cantilevers overhang by about 5 feet the centers of their supports on the distributing girders above the grillages of the high-level footings close to the lot line. The long ends are riveted to the sides and faces of interior columns which are carried down to seats on piers below the basement floor with their grillages about 11 feet lower than those of the wall column piers. Although column 2 which supports the inner end of cantilever girder 1-2 is outside the retaining wall, its footing was carried down below the basement floor level, the same as columns 22 and 25 at the inner ends of the other cantilevers, and the excavation for it was made so as to receive the footing for the underpinning of the adjacent wall of the next building, as indicated by the dotted lines in the general elevation of girder 1-2. This cantilever, like all the others, was encased in a solid rectangular mass of concrete 3 inches thick beyond all sides. The column was protected by a similar casing up to the basement floor, and the excavation was back-filled as shown.

Cantilever girder 1-2 has two full length webs, which, as shown in the detail, are connected at the end of the long arm to the reaction column 2 by transverse horizontal angles across the top and bottom flanges. The lower angles are merely shelves for convenience in supporting the weight of the cantilever during erection. The upper angles receive all the upward reactions and are reinforced in the usual way by vertical angles fitted to their horizontal flanges, and having sufficient rivets through the column cover plates to distribute all the stresses there. The two main girder webs are connected only by top and bottom flange tie plates and by a vertical transverse diaphragm near the center which receives the end of a third web extending to the extremity of the short arm to help carry the wall column. The cantilever thus consists essentially of three separate plate girders, two of them full length and one, half length. The other foundation cantilevers are similar to the one here illustrated except in their dimensions and in their connections to the reaction columns. Girder 22-23 is 30 inches deep and girder 24-25 is 36 inches deep, both being 30 feet long. The long arms of both are connected, as shown at interior column 22, with the end of their two long webs engaging the column and completely covering both its faces with 2 or 3 inches clearance and no web riveted connection. All the stress is transmitted through the flanges to the standard reinforced brackets which cover the full widths of the column faces.

Comments on Technical Education.

Extracts from an address by Prof. John Perry before the Engineering Section of the British Association.

Mathematics.—It seems probable that at the end of another five years no average boy of fifteen years of age will have been compelled to attempt any abstract reasoning about things of which he knows nothing; he will be versed in experimental mathematics, which he may or may not call mensuration; he will use logarithms, and mere multiplication and division will be a joy to him; he will have a working power with algebra and sines and cosines; he will be able to tackle at once any curious new problem which can be solved by squared paper; and he will have no fear of the symbols of the infinitesimal calculus. When I insist that a boy ought to be able to compute, this is the sort of computation that I mean. Five years hence it will be called "elementary mathematics." Four years ago it was an unorthodox subject, called "practical mathematics," but it is establishing itself in every polytechnic and technical college and evening or day science school in the country. Several times I have been informed that on starting an evening class, when plans have been made for a possible attendance of ten or twenty students, the actual attendance has been 200 to 300. Pupils may come for one or two nights to a class on academic mathematics, but then stay away forever; a class in practical mathematics maintains its large numbers to the end of the winter.

Hitherto the average boy has been taught mathematics and mechanics as if he were going to be a Newton or a Laplace; he learnt nothing, and became stupid. I am sorry to say that the teaching of mechanics and mechanical engineering through experiment is comparatively unknown. Cambridge writers and other writers of books on experimental mechanics are, unfortunately, ignorant of engineering. University courses on engineering—with one splendid exception, under Professor Ewing, of Cambridge—assume that undergraduates are taught their mechanics as a logical development of one or two axioms; whereas in many technical schools under the Science and Art Department apprentices go through a wonderfully good laboratory course in mechanical engineering. We really want to give only a few fundamental ideas about momentum and the transformations of energy and the properties of materials, and to give them from so many points of view that they become part of a student's mental machinery, so that he uses them continually. Instead of giving a hundred labor-saving rules which must be forgotten, we ought to give the one or two ideas which a man's common-sense will enable him to apply to any problem whatsoever, and which cannot be forgotten. A boy of good mathematical attainments may build on this experimental knowledge afterwards a superstructure more elaborate than Rankine, or Kelvin, or Maxwell ever dreamt of as being possible. Every boy will build some superstructure of his own.

Laboratory Instruction.—The professors were given a free hand at Finsbury, and there were no outside examiners. I need not dwell upon the courses in chemistry and physics; some critics might call the subjects "rational chemistry" and "applied physics;" they were as different from all other courses of study in these subjects as the courses on rational mathematics and mechanics differed from all courses elsewhere. The course on mechanics was really one on mechanical engineering. There were workshops in wood and iron, not to teach trades, but rather to teach boys the properties of materials. There were a steam engine and a gas engine, and shafting and gearing of many kinds, and dynamos which advanced students in turn were allowed to look after under competent men. There was no machine which might not be experimented with occasionally. Elementary and advanced courses of lectures were given; there was an elaborate system of tutorial classes, where numerical and squared paper exercise work was done; there were classes in experimental plane and solid geometry, including much graphical calculation; boys were taught to make drawing-office drawings in pencil only, and tracings and blue prints, such as would be respected in the workshop, and not the ordinary drawing-class drawings, which cannot be respected anywhere; but the most important part of the training was in the laboratory, in which every student worked, making quantitative experiments. An offer of a 100-ton testing machine for that laboratory was made, but refused; the advanced students usually had one opportunity given them of testing with a large machine, but not in their own laboratory. I consider that there is very little educational value in such a machine; the student thinks of the great machine, and not of the tiny specimen. Junior students loaded wires and beams, or twisted things with very visible weights, and saw exactly what was happening, or they studied vibrating bodies. Many hours were devoted to experiments on a battered, rusty old screw-jack, or some other lifting machine, its efficiency under many kinds of load being determined, and students studied their observations, using squared paper, as intently as if nobody had ever made such experiments before. There was one piece of apparatus, an old flywheel, bought at a rag-and-bone shop, to which kinetic energy was given by a falling weight, which I remember occupied the attention of four white-headed directors of electric companies in 1882 (evening students) for many weeks. A casual first measurement led on to corrections for friction and stiffness of a cord, and much else of a most interesting kind. At the end of six weeks these gentlemen had gained a most thorough computational acquaintance with every important principle of mechanics, a knowledge never to be forgotten. They had also had a revelation such as comes to the true experimenter—but that is too deep a subject.

Perhaps teachers in the greater colleges will smile in a superior way when they hear of this kind of experimental mechanics being called engineering laboratory work. True, it was elementary mechanics; but is not every principle which every engineer constantly needs called a mere elementary principle of mechanics by superior persons? I find that these elementary principles are very much unknown to men who have passed through elaborate mathematical studies of mechanics. Students found out in that laboratory the worth of formulæ; they gained courage in making calculations from formulæ, for they had found out the extent of their own ignorance and knowledge.

At Finsbury there was an excellent one-cylinder engine with vaporizing condenser. It drove the workshops and electric generators. On a field-day it drove an electric generator only, and perhaps thirty students made measurements. Each of them had already acted as stoker and engine-driver, as oiler and tester of the machinery, lighting fires, taking indicator diagrams, weighing coals, opening and closing cocks from seven in the morning to ten at night, so that everything was well known to him. They maintained three different steady loads for trials of three hours each. They divided into groups, one from each group ceasing to take a particular kind of observation every ten minutes and removing to another job. All watches were made to agree, and each student noted the time of each observation. These observations were: Taking indicator diagrams, checking the speed indicator, taking temperature of feed water, quantity of feed by meter (the meter had been carefully checked by gauge-notch, and every other instrument used by us had been tested weeks before), taking the actual horse-power passing through a dynamometer coupling on the shaft, taking boiler and valve-chest pressures and vacuum pressures on the roof and in the engine-room, weighing coals (the calorific value had already been tested), taking the horse-power given out by the dynamo, counting the electric lamps in use, and so on. Each student was well prepared beforehand. During the next week he reduced his own observations, and some of the results were gathered on one great table. One lesson that this taught could never be forgotten—how the energy of 1 lb. of coal was disposed of. So much up the chimney or by radiation from boiler or steam jacket and pipes; in condensation in the cylinder; to the condenser; in engine friction; in shaft friction, etc. I cannot imagine a more important lesson to a young engineer than this one taught through a common working engine. The students had the same sort of experience with a gas engine. I need hardly say how important it was that the professor himself should take charge of the whole work leading up to, during, and after such a field day.

Teachers.—Mathematics and physics and chemistry are usually taught in watertight compartments, as if they had no connection with one another. In an engineering college this is particularly bad. Every subject ought to be taught through illustrations from the professional work in which a student is to be engaged. An engineer has been wasting his time if he is unable to answer the questions of an ordinary examination paper in chemistry or pure mathematics. The usual mathematical teacher thinks most of those very parts of mathematics which to an ordinary man who wants to *use* mathematics are quite valueless, and those parts which would be altogether useful and easy enough to understand he never reaches; and, as I have said, so it is also in chemistry. Luckily, the physics professor has usually some small knowledge of engineering; at all events, he respects it. When the pure mathematician is compelled to leave the logical sequence which he loves to teach mechanics, he is apt scornfully to do what gives him least trouble—namely, to give as "mechanics" that disguised pure mathematics which forms 90 per cent. of the pretence of theory to be found in so many French and German books on machinery. As pure mathematical exercise work it is even meaner than the stupid exercises in school algebras; as pretended engineering it does much harm, because a student does not find out its futility until after he has gone through it, and his enthusiasm for mathematics applied to engineering problems is permanently hurt. But how is a poor mathematical professor who dislikes engineering, feeling like Pegasus harnessed to a common wagon—how is he to distinguish good from evil? He fails to see how worthless are some of the books on "Theoretical Mechanics" written by mathematical coaches to enable students to pass examinations. An engineer teaching mathematics would avoid all futilities; he would base his reasoning on that experimental knowledge already possessed by a student; he would know that the finished engineer cannot hope to remember anything except a few general principles, but that he ought to be able to apply these, clumsily or not, to the solution of any problem whatsoever. Of course, he would encourage some of his pupils to take up Thomson and Tait, or Rayleigh's "Sound," or some other classical treatise as an advanced study.

Not only do I think that every teacher in an engineering college ought to have some acquaintance with engineering, but it seems to me equally important to allow a professor of engineering, who ought, above all things, to be a practical engineer, to keep in touch with his profession. A man who is not competing with other engineers in practical work very quickly becomes antiquated in his knowledge; the designing work in his drawing-office is altogether out of date; he lectures about old difficulties which are troubles no longer; his pupils have no enthusiasm in their work; even when he is a man distinguished for his past work, his students have that kind of disrespect for his teaching which makes it useless to them. If there is fear that too much well-paid professional work will prevent efficiency in teaching, there is no great difficulty in applying a remedy.

A Slide-Rule for Field Topographic Work.

Of making slide-rules for special purposes there seems to be no end, and the novel features of most of the new designs are too minute to be of general interest. For several years, however, Mr. Gerard H. Matthes, of the U. S. Geological Survey, has been using a metal rule for reducing stadia observations in the field, which merits general notice. It is made of German silver and thus is unaffected by temperature or humidity, and in plane table work has made it unnecessary to employ more than one man, a rodman, to assist in the survey. It has proved particularly useful in windy weather when books of tables or diagrams are blown about so as to be very troublesome. The instrument is 10½ inches long and was made by Kern & Company, of Aarau, Switzerland. The following account of it and its use is abridged from the "Technology Quarterly" for September. As the plane table work of the Survey must be understood in order to appreciate the value of the rule, a few notes on the operations are first given.

The operations may be classed under two heads: Vertical angle or intersection work, and stadia work. In the former, prominent features are located on the map by intersection from two or more known points, vertical angles being determined in each instance. The vertical difference of elevation between each point of observation and the new point is then computed by multiplying the horizontal distance (scaled from the map directly) by the tangent of the angle, and applying corrections for the effects of curvature of the earth, refraction of the atmosphere, and the height of the telescope above the ground. Computations of this character are made for each observation, thus affording a reliable check upon the elevation of the new point. It will be noticed at once that these computations are not simple. The distance scaled from the map is obtained in terms of miles. The difference of elevation required must be in feet. Effects of curvature and refraction are variable quantities. It is essential that the correct functions be used in computing these corrections, for no rule of thumb or approximate method can be relied upon to give accurate results.

The other class of work referred to above, in which distances and elevations are determined by the stadia method, is too well known to require description here. In the general topographic work of the Survey its use is chiefly confined to stadia traversing and large-scale surveys of reservoir sites or mining districts. The reduction of stadia observations is also performed with the aid of tables. The formulæ involved are as follows:

Vertical difference of elevation $= 100\,R\,\dfrac{\sin 2A}{2}$

Correction to distance for inclination of line of sight $= 100\,R\,\cos^2 A$

where R is the rod reading in feet, and A the vertical angle read to a point on the rod at a height above the ground equal to the height of the instrument. These formulæ do not take into account the corrections for focal length and the distance of the objective from the center of the instrument, but these are so small as to be negligible.

In intersection work distances occur from a fraction of a mile up to 15 miles or more; distances exceeding 10 miles are avoided, however, since an error of one minute in the vertical angle will affect the elevation 16 feet at a distance of 10 miles, and 23 feet at a distance of 15 miles, while the uncertainty of refraction for such distances becomes very great. The vertical angles are usually small, except in canyon or high mountain topography.

In stadia work distances are short, rarely exceeding 2,500 feet, while, on the other hand, the vertical angles are as a rule larger than in intersection work, though seldom exceeding 30 degrees.

The slide-rule is capable of making all the operations described, and while it is not expected that it will entirely replace the tables now in use, it is believed that many topographers will prefer it as being more rapid and serviceable than any existing tables. In canyon and high mountain topography, however, where vertical angles of great amplitude are frequent, tables will be found more satisfactory.

Following is a description of the graduated scales of the rule:

Scale A contains the logarithms of common numbers from log 1 up to log 100, plotted from left to right to a scale of log 10=12.5 c.m., and is to be used as a scale of distances in *feet.*

Scale B contains the same graduations as Scale A, the difference being that the initial point is at a different place. The arrangement of the two scales with respect to each other is such that distances on Scale B in terms of *miles*, correspond with their equivalents in terms of *feet* on Scale A, thus providing a convenient means of conversion from one unit of length into the other. Scale B commences with a distance of 0.19 mile and ends with 19 miles.

Scales C and D, marked "Vertical Angles," are provided with graduations corresponding to the logarithmic tangents of angles, and are plotted from right to left, being negative quantities. Scale D commences on the right with 00° 03′ 30″ and ends with 05° 40′; Scale C duplicates these angles from 00° 35′ to 05° 40′, and carries the graduations up to 30° 00′. Asterisks have been placed opposite indices used for reading the differences of elevation on Scale E; their use will be explained further on. They are of importance in another connection, however, as they indicate the angles for which the differences of elevation are respectively 0.001, 0.01, and 0.1 times the horizontal distance, taking them in order from right to left; and if imagined projected on Scale C they represent the angles for which the differences of elevation likewise are 0.01, 0.1, and 1 times the horizontal distance. In this manner they are a valuable aid in determining the location of the decimal point when reading difference of elevation.

Scale E is identical in all respects with Scale A, and is to be used for obtaining the vertical difference of elevation between the point occupied by the instrument and the point sought, as hereinafter explained.

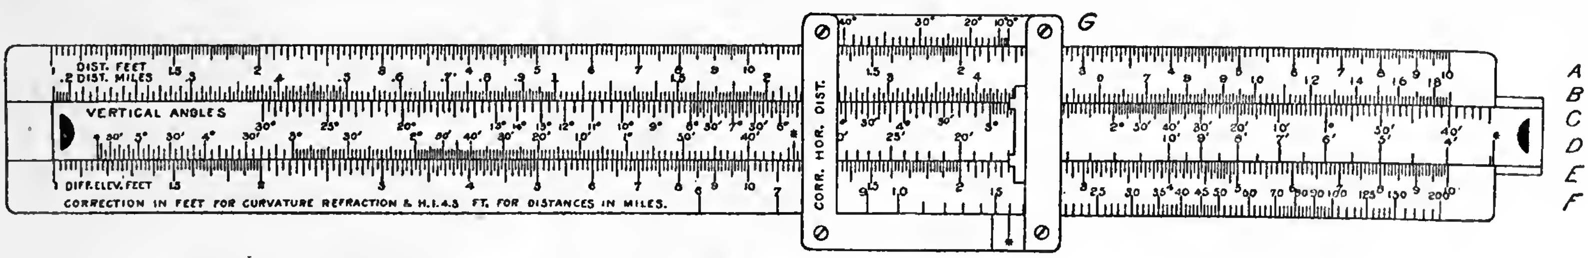
Scale F. In the construction of this scale use was made of the formula

$$D_m = \sqrt{\frac{C - R + 4.5}{0.574}}$$

in which D_m is the horizontal distance in miles, C and R the corrections in feet for curvature and refraction, respectively, while the quantity 4.5 is a constant positive correction for the height of the telescope above the ground, the assumption being that as a rule this height is in the vicinity of 4.5 feet. The second member of the equation is always positive. The graduations on Scale F are merely the logarithmic distances in miles corresponding to corrections in even feet, and are plotted on the same basis as the distances in miles on Scale B. Scale F, therefore, gives the correction for curvature, refraction, and height of instrument combined, for any distance (in miles) on Scale B, commencing with a correction of 6 feet for a distance of 1.62 miles, and ending with a correction of 200 feet for a distance of 18.45 miles. For any distance less than 1.5 miles, the correction may be taken as + 5 feet.

Scale G (on the rider) contains the logarithms of the squares of cosines of angles from 0° to 40°. Being negative, they are laid off from right to left. The first graduation to the left of the 0° mark represents an angle of 4°; the succeeding ones stand for 6°, 8°, 10°, etc., up to 20°, from which point on the graduations represent single degrees.

Scales H and I, marked "Stadia Angles," are on the reverse side of the slide and do not appear in the illustration. They are similar in character to Scales C and D described above, and contain the logarithms of ½ sin 2*A*, where *A* is the vertical angle in stadia observations. The statements made in regard to Scales C and D apply equally to Scales H and I, except that the graduations on Scale I extend from 00° 03′ 30″ to 05° 45′, and on Scale H from 00° 35′ to 40° 00′. The asterisks are placed as before, and will also be found useful in determining the position of the decimal point in obtaining the difference of elevation.



German Silver Slide Rule for Field Use in Topographic Surveying.

The 0° mark of Scale G, the pointers of the rider, and the index on the lower portion of the rider are in line with one another. This line is at right angles to the axis of the rule, and serves to project readings from any one scale to any other.

1. Given the distance to a point in *feet*, to convert the same into *miles*, or *vice versa.* To convert feet into miles, set the 0° graduation of the rider opposite the distance in feet, 2,350 feet in the illustration, and read the answer 0.445 mile on Scale B, opposite the pointers. The same result could also have been obtained by using the left portion of the rule. In either operation the position of the decimal point is determined mentally.

2. Given the distance to a point in *miles*, required the correction for curvature and refraction, and for height of instrument. Set the pointers of the rider opposite the distance in miles on Scale B, and read the desired correction on Scale F opposite the index on the lower limb of the rider. Thus in the illustration, for a distance of 4.45 miles the correction is

found to be nearly 16 feet. The graduations on Scale F hold good only for distances in miles using Scale B without shifting the decimal point.

3. Given the distance to a point in *miles*, and the vertical angle, required the difference of elevation in *feet*, neglecting corrections for curvature, refraction, and height of instrument. The pointers of the rider are brought opposite the given distance in miles on Scale B. The slide bearing the graduations marked "Vertical Angles" is then moved until the desired angle is brought opposite the pointers of the rider, as for instance in the illustration, a distance of 4.45 miles on Scale B, and an angle of 17 minutes on Scale D. The difference of elevation in feet, 116, is then obtained from Scale E by reading opposite any one of the asterisks of Scale D. It will be noticed that with the same position of the slide, the angle 2° 50′ is brought opposite the pointers. The difference of elevation for this angle and the same distance is therefore read the same way, only the result is ten times as large, or 1,160 feet, which is within 2 feet of the computed answer. The topographer will rarely be in doubt as to the position of the decimal point in obtaining his answer, as a glance at the topography will determine whether the result should be 116 or 1,160 feet. However, should a doubtful case arise, the correct reading may be determined readily by remembering that for any angle between 00° 03′ 30″ and 00° 34′ the difference of elevation will range from 0.001 to 0.01 times the distance in feet; likewise for angles between 00° 34′ and 05° 43′ it will range from 0.01 to 0.1 times the distance in feet, and for angles between 05° 43′ and 45° 00′ the range will be from 0.1 to 1 times the distance in feet. The positions of the asterisks will be found a great aid in remembering these points.

Attention is called to the fact that the correction for curvature, refraction, and height of instrument for the distance in question may be read off as explained under (2), without further manipulation of the instrument.

4. Given the stadia rod-reading in *feet* and the vertical angle to a point, required the difference of elevation in *feet*. The 0° graduation of the rider is brought opposite the stadia rod-reading in feet on Scale A. Reversing the slide and having the side marked "Stadia Angles" uppermost, use it in precisely the same manner as before, reading the difference of elevation on Scale E, opposite any one of the three asterisks of Scale I. As in the preceding case the angle may occur either on the upper or lower scale of that side of the slide. The position of the decimal point may be determined again by noting that for vertical angles between 00° 03′ 30″ and 00° 34′ the difference of elevation will range from 0.001 to 0.01 times the rod-reading; for angles between 00° 34′ and 05° 46′ it will range from 0.01 to 0.1 times the rod-reading, and for angles between 05° 46′ and 45° 00′ it will range from 0.1 to ½ times the rod-reading.

5. Given the stadia rod-reading in *miles* and the vertical angle to a point, required the difference of elevation in *feet*. The problem is the same as the preceding, except that the stadia rod-reading is in terms of miles and Scale B is to be used instead of Scale A, the remainder of the process being the same.

6. Given the stadia rod-reading and the vertical angle to a point, required the correct horizontal distance. This problem usually occurs in connection with either of the preceding cases and may be solved without further manipulation of the rider after the latter is set for their solution.

When the rod-reading is in feet, read Scale A opposite the vertical angle in question on Scale G of the rider, marked "Cor. Hor. Dist.," the result being the *correct horizontal distance*.

When the rod-reading is in miles, note the point on Scale A opposite the vertical angle on Scale G and move the 0° graduation to it, when in so doing the pointers will be brought opposite the correct horizontal distance in miles on Scale B.

The graduations on all the scales, with the exception of the one for curvature, refraction, and height of instrument, being logarithmic quantities plotted to a certain unit scale, the distances between graduations vary from point to point, requiring changes in the manner of subdividing in order to maintain clearness. The consequent result is that the precision is different for different parts of the scales, varying with the spacing of the graduations. An inspection will prove, however, that the resultant degree of precision for any particular operation of the instrument is always greatest where most required, *i. e.*, for cases of most frequent occurrence, while it is less for cases of rare occurrence. Thus, for a distance of 5.78 miles scaled from a map, and an angle of + 01° 02′, a common observation in topographic work such as is daily being done by topographers of the United States Geological Survey, the rule will give a difference of elevation of 550 feet at a point on the scale where single feet may readily be estimated, and a correction for curvature, refraction, and height of instrument of 24 feet, readily obtained without interpolation, from which the resulting difference of elevation of the point sought becomes 574 feet, *i. e.*, a result the correctness of which to the nearest foot leaves no doubt. Again, for a distance of 0.85 mile and an angle of — 6° 04′ the rule gives a difference of elevation of 477 feet, which corrected for height of instrument by the amount of 5 feet, the effect of curvature and refraction being very small for that distance, reduces the final difference of elevation to — 472 feet, a result reliable in all respects to the nearest foot.

On the other hand, cases may occur, though the exception rather than the rule, where a distance is observed of say 3.65 miles and a vertical angle of 20° 10′. The computed difference of elevation, neglecting effects of curvature and refraction, in this instance, is 7,078 feet, but the slide-rule will give the result to only the nearest 10 feet, 7,070 or 7,080 feet, according to estimation. In other words, in observations of this character the rule can not be relied upon to give the answer within less than 10 feet. An error of this magnitude, however, in an observation of the kind mentioned, can not be considered serious, as the very nature of the observation is not conducive to anything more than approximate results; and it may safely be said that any topographer who carries on work of this character is doing very well if his elevations will check to within 10 feet by means of tables or by direct computation.

Residential Septic Tanks seem to have been in use some time ago in King's Lynn, England, according to a statement made by Mr. E. J. Silcock, of Leeds, at the recent meeting of the Association of Municipal and County Engineers, at King's Lynn, as reported in "The Surveyor." He stated that they were not actually septic tanks, but rather decomposing chambers, each house having one. Each chamber was a brick structure, 4x2 feet, with an outlet dipping down into the sewer. Usually it was outside, but sometimes in the house. The object was really to form a trap between the sewer and the house. As a matter of fact it did form a septic tank, and practically nothing but liquid came away from the chamber. Mr. Silcock had seen many of them opened and said that they had a great effect in liquefying the sewage. Similar tanks at Bowling Green, O., and Zion City, Ill., are discussed in this and previous issues.

City Bench Marks in Hartford, Conn.

Mr. Frederick L. Ford, city engineer of Hartford, Conn., has compiled information relating to an extensive new system of bench marks established throughout the city and has published it in convenient form in a book 3½x6¾ inches in size. The book is neatly bound in flexible Morocco covers and has several leaves of blank ruled paper at the back for additional notes. The style of the records is illustrated by a portion of a page, which we reproduce:

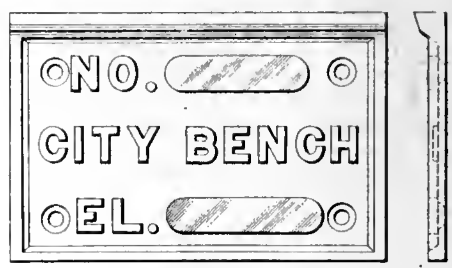
CLARK STREET.

Capen Street—El. **97,509.** S. W. cor. next to bottom stone step 62-64 Capen Street 2nd house E. of Clark St.—No. 221.

Elmer Street—El. **98,.62.** Bench plate S. E. cor. 47 Clark Street, opposite N. line of Elmer Street—No. 222.

Nelson Street—El. **97,619.** Stone water table S. W. cor. 104 Clark Street opposite N. line of Nelson Street—No. 223.

According to Mr. Ford, this book represents the labors of two seasons of very careful leveling work, great pains being taken to produce a most reliable system of benches covering the entire city. In executing the field work an 18-inch Buff & Berger Y level and a Philadelphia Rod with patent rolling angle target were used. The city was divided into sections, and two sets of levels run around the limits of each, one in each direction, the levelman and rodman changing places in each second circuit, to eliminate as far as possible personal errors. After each main circuit of elevations was determined by careful adjustments, benches were established on all intermediate streets by carefully checking the elevations with those of the main circuit as often as convenient.



HARTFORD BENCH PLATE.

As it proved to be a difficult matter to find permanent and convenient objects on which to establish benches in the outskirts of the city, most of the buildings being wooden structures, bench plates were prepared of cheap composition metal and screwed securely to the base boards of houses where benches were to be located. Many of these plates were put on corners of houses standing at street intersections so that they are available from either street. The plates are 2⅝x4 inches in size and are of the design shown herewith, the letters and the spaces for the figures raised. The top is nearly ⅜-inch wide and overhangs the lower part of the plate.

As some of these benches will be destroyed by the removal of buildings upon which they are located and as new ones will be established in their places, and on newly opened streets, engineers receiving a copy of this book were advised to compare their book with the "Official Copy" at the City Engineer's office at least once a year and make the necessary corrections on the blank pages in the back of each book. Every engineer in the vicinity of Hartford has been presented with a copy by the city engineer and they will no doubt prove of great benefit to all and at the same time reduce all leveling work in Hartford to a uniform basis and avoid the necessity of ever using assumed elevations to work from.

Economy in the Use of Coal for the Production of Power.

Abstract of a paper read by Prof. Ira N. Hollis, of Harvard University, at the meeting of the New England Water-Works Association, November 12. The complete paper will be published in the forthcoming number of the "Journal" of the New England Water-Works Association.

A pound of good coal is capable of yielding from 14,000 to 15,000 heat units during combustion, equal, if all transmitted into work, to between 10,892,000 and 11,670,000 foot pounds. When used for heating purposes, as in reducing and blast furnaces, a very large percentage of this heat is lost at once; and when used in a boiler to drive a steam engine, a still larger percentage is lost, first in the boiler and next in the cylinders of the engine. Under the most favorable conditions in practice, only 1,320,000 foot pounds are recovered from each pound of coal, more than 88 per cent. of its heat value being wasted. For every ton that is burned in a power house, nearly 7½ tons are thrown away.

The total possible saving in the steam boiler would be about 34 per cent. of the heat of the coal. This reckons the boiler at 66 per cent. efficiency. Of the 34 per cent. referred to, we cannot hope to get back more than half, as fully 17 per cent. is required for draft, even when using an economizer. This leaves as the maximum possible efficiency of a boiler 83 per cent. In the case of the steam engine, the efficiency is governed by the thermo-dynamic law that the work is proportional to the range of heat. If, therefore, the upper temperature of steam be taken at 900 absolute, and the lower at 600, the ideal efficiency would be 33 1/3 per cent., which is rarely even approached. The highest mechanical efficiency that the author has ever been able to find between the steam cylinder and the power to which it is applied is in the Cambridge pumping engine, designed by Dr. E. D. Leavitt, in which the work done in the pump was slightly over 96 per cent. of the power developed in the cylinders, an efficiency of 96 per cent. Multiplying these three efficiencies together, the maximum attainable efficiency under ideal conditions is 26½ per cent. That is, nearly three-fourths of the heat of the coal must be thrown away, even under ideal conditions, for the working of a steam engine. With the most economical of modern engines, a horsepower has been obtained from 11 pounds of steam, or even slightly less. This gives about 12 per cent. efficiency. What is sought, therefore, is the remaining 14½ per cent., and it must be remembered that under no conditions is it practicable, with the present materials for engines and boilers, to gain more. Engineers may well strive to strike out on a new path. We are struggling with the steam turbine and with other inventions to save a few pounds of coal, while wasting tons. Compare the efficiency of a steam plant with that of a battery using zinc, in which the greater part of the heat is turned into current and thus utilized at once as power.

One of the axioms of modern engineering is that the condition most favorable to economy is the regular and constant demand for power. Where an engine is to be run at its designed maximum power for twenty-four hours a day, the entire plant can be made to realize a much higher efficiency than would be the case with a fluctuating demand for work. Where this fluctuating demand prevails, the plant must be designed for the greatest output, and yet used for long periods at much lower rates. This is like employing a man to do the work of a small child, because at times there are weights to be lifted that require a man's strength. Furthermore, paradoxical as it may seem, there are many cases in which economy would be obtained only at too great a cost, a good example of this being found in steam engines for small powers. It would not pay to build a 1-horsepower engine with a steam jacket and condenser and air pump. The first cost would be too great, and the skill to render the design effective would be far beyond the ordinary rate of wages. The line of improvement in the use of small powers is clearly pointed out: a central station which can be kept working at a constant rate, and some efficient method of distribution to motors of such simplicity that cheap labor can be employed to run them. This may be called the problem of the twentieth century, inasmuch as there are many demands for small quantities of power to a comparatively few for power in large quantities.

Economy in the use of coal is thus divided under three heads:

1. Efficiency in the recovery of heat after combustion.
2. Efficiency of the medium by which the heat is transmitted into work.
3. Efficiency in the work developed in the prime mover of the machine which applies it directly to the useful result.

When we consider that under these three elements of efficiency, exhaustive experiments, extending over a hundred years, have enabled us to transform under ordinary conditions less than 10 per cent. of the heat of the coal into a useful work, we realize the great field still open to engineers.

In a steam plant, the boiler forms, naturally, the first element for study. Its efficiency is so much a question of the men who run it that we have arrived at no final type which may be expected to give the highest results. Any well-designed boiler will recover from the coal about 75 per cent. of its heat, under the most favorable conditions. This fails to 40 and 50 per cent. with bad management, and it may rise to 85 per cent. with the addition of some device, usually separate from the boiler, for utilizing the waste heat. The following table taken from a boiler trial reported in 1894 and republished in Mr. Bryan Donkin's book, "Heat Efficiency of Steam Boilers," may serve a useful purpose in indicating the heat utilized and lost. The data was obtained from two Lancashire boilers and a Green economizer, and it is sufficiently near the average fair practice to serve as a type. A slight modification has made possible the placing of all the data in one table:

	British thermal units.	Per cent.
Heat transmitted to water in boiler	8,271	55.2
Heat transmitted to water in economizer	1,637	10.9
Heat lost in products of combustion	1,127	7.5
Heat lost in excess air	985	6.6
Heat lost in moisture from coal	23	.2
Heat lost in air leaking through brickwork of economizer	259	1.7
Heat lost in unburnt coal	342	2.3
Heat not accounted for, including radiation	2,342	15.6
Total	14,985	100.0

The third item in the table represents an unavoidable loss in one form or another. Combustion is produced by the contact of oxygen with combustible material at a temperature which causes a chemical combination. The continuous combustion of coal is possible only with a regular supply of air and an equally regular withdrawal of waste products. Work is required to provide this constant current or draft, either in the form of heat supplied directly by the fuel or indirectly by means of power obtained from the steam. Under either condition a considerable amount of heat is lost which, apparently, can never be saved by any inventions affecting the steam boiler. Usually both losses occur when blowers are used, as it is never possible to discharge the products of combustion at the temperature of the air. In the case of a boiler without a feed water heater, they can never be below the temperature of the steam. The table shows that 1,127 heat units are thus lost even with an economizer. Without it, the quantity would have been above 2,000. Complete combustion is not possible without an excess of air, and thus the gain brings with it a considerable loss, as the heated air is discharged at the same temperature as the products of combustion. With blowers, this excess is likely to be greater than with a natural draft. The regular supply of air is an absolute essential of economy when the supply of coal is also constant. Air entering irregularly signifies loss of efficiency. It is in this respect that the various forms of mechanical stokers have the advantage of firing by hand. The total heat lost up the chimney from a furnace would appear by the table to be about 2,100 heat units, or 18 4/10 per cent. Two methods have been worked out for recapturing some of this heat, and of these the feed water heater has played by far the more important part. It has taken on various forms, but the Green economizer is that which has seemed most effective. Any arrangement by which the feed pipes are placed in the paths of the products of combustion, will add to the economy of the boiler; although it may also add to the repair bill.

Attempts have been made to heat the air supplied to the furnace by means of the waste products, and the Howden system has proven successful in this respect. A fan is necessary for its operation, and work is thus expended by the blowing engine in the production of draft. One point worthy attention in connection with all hot air blasts is that the amount of oxygen in one cubic foot of air is inversely proportional to the absolute temperature. Consequently at a high temperature a greater volume of air must be supplied to consume a given weight of coal. It is therefore more difficult to drive hot air in burning coal than cold air. There is much to be said on the subject of the location of a blower, whether it be in the fire room and used to force draft by pressure in the ash-pan, or in the uptake, where it creates a vacuum to induce draft. In the latter case, the temperature of the products of combustion must be kept comparatively low in order to prevent an injurious change of shape of the fan.

Intimately connected with the economical combustion of coal is the prevention of smoke, the latter meaning only so much unburnt carbon passing off into the air, to drop on everything in the neighborhood. In the main, it may be said that devices for smoke combustion lead to economy in the use of coal, but they often increase the total expenditure of money per year. The cost of coal is only part of the total expense, and repairs to smoke consumers and patent furnaces are often large. Unless a plant is of considerable size and is run continuously, they are of doubtful value. The various forms of mechanical stokers have the advantage over firing by hand both in economy and in smoke prevention. Much might be accomplished by better laws in regard to licensing firemen. It has always seemed to me that a first rate fireman with the ordinary grate is equal to any form of patent furnace, especially where there is a fluctuating demand for heat. There is a vastly greater difference between a good fireman and a bad fireman than there is between a mechanical stoker and a good fireman. A good school for teaching firemen would be more fundamental than mechanical devices of any kind. Yet it is only fair to add that the cheaper grades of coal can be burned on patent stokers, where the feed is regular. This is a decided advantage, and, furthermore, the extensive use of soft coal must of necessity develop a good smoke consumer. Some are now satisfactory. A few years ago the author ran a series of tests with a patent furnace in order to compare its results with those obtained from an ordinary grate in a boiler alongside of it. The patent furnace was something like the Murphy automatic furnace, only it had a broader plate in the bottom. The coal was fed in on the sides, and a warm blast was thrown down over it throughout the length of the furnace. This blast was caused by an ordinary Sturtevant blower. A dozen or more tests were run with the boiler, which was of the ordinary underfired type, and it was found that on the whole it was not so economical in the production of steam as the ordinary grate. In the reduction of smoke it was very effective, by diluting the products of combustion with air to such an extent that the smoke seemed to be only a small percentage of the discharge from the chimney. The neighboring boiler with the plain grate discharged into the same chimney and was watched very carefully, when run by a first-rate fireman. The amount of smoke was undoubtedly in excess of that discharged from the patent device, even when great care was exercised in the firing, but not to the extent usually seen in the ordinary factory chimney. The amount of steam produced per pound of coal was fully up to the very best practice.

It seems strange that up to the present time no satisfactory method of keeping the heating surfaces of boilers clean has yet been devised. The loss of heat chargeable to this account is very great, and the loss of money is still greater. It is found necessary to provide heating surface thirty-five or forty times the grate surface to attain any kind of efficiency, yet an effective method of cleaning the surfaces would permit reducing them very materially, and thus lessening the amount of material put into a boiler of given horse power. The tubes of ordinary boilers are always more or less dirty and the water side of the tubes is almost continuously coated with some non-conducting substance. The author had seen a ship gain a knot's speed simply by blowing through the tubes with steam, and that without the expenditure of a pound more coal.

The small losses, shown in the table, from moisture, and leaks through the brick-work, and unburnt coal are sometimes serious, but they are simply matters of care. If a fireman is allowed to turn the sprinkler on coal, he is likely to cost his employer dear in the course of a year. The same may be said of too frequent cleaning of fires. The leaks through the brickwork are greater than usually reckoned, and they are avoidable only by constantly plastering up the outside. It has sometimes seemed to me that a sensible gain in economy would result from plastering the outside of a brick setting so that every crack would appear at once upon its development. In the table the loss "not accounted for," as in radiation, requires some study, as it appears to be quite a large percentage. There is always this unaccountable deficiency, greater or less according to the care exercised in the test which has been made.

When we turn to the steam engine we find greater losses than in the boilers. The first and most serious loss in a steam cylinder is from initial condensation. Although the steam jacket has done much to mitigate this loss, it should still be used with judgment. The author lately ran a test which showed that there is such a thing as over-jacketing an engine and losing heat by too much jacket steam. The case is of a triple-expansion engine which developed about 533 horse-power. The steam was supplied to the high pressure cylinder at 181 pounds, and it passed successively through the high pressure cylinder, the working side of the first reheater, the intermediate cylinder, the working side of the second reheater, and the low pressure cylinder, into the condenser. Every cylinder and reheater was thoroughly jacketed with high pressure steam from the boiler, and the exhaust from the low pressure cylinder passed into the condenser with steam superheated 100 degrees. The record of economy was about as follows:

Without any steam on the jacket or reheaters, the steam supplied to the engine was 12.19 pounds per indicated horse power.

With full pressure on all jackets, the steam used was 12.09 pounds per indicated horse power. No substantial gain.

With steam on only the high pressure and intermediate jacket and on the first reheater, the amount of steam supplied to the engine was 11.47 pounds per indicated horse power.

Calculations on initial condensation seem very inaccurate excepting where a careful test has been made of the tightness of all valves. Gridiron valves seem, on the whole, most satisfactory. They are far preferable to piston valves, as their tendency is to become tighter with wear, while the tendency of piston valves is to become looser.

Extent of Damage to Williamsburg Bridge Cables.

Mr. Gustav Lindenthal, M. Am. Soc. C. E., Commissioner of Bridges, has appointed a special commission to examine into the extent of damage and the methods by which repairs can best be made to the main cables of the Williamsburg Bridge, which were affected by the fire of November 10. The members of this commission are Mr. George S. Morison, consulting engineer, Mr. C. C. Schneider, vice-president of the American Bridge Company, and Mr. Leffert L. Buck, consulting engineer of the Williamsburg Bridge, all members of the American Society of Civil Engineers. The fire was fully described in last week's issue of The Engineering Record, and some of the more apparent damages to the bridge noted. In his weekly report to Commissioner Lindenthal, Mr. O. F. Nichols, M. Am. Soc. C. E., engineer in charge of the bridge, presents a statement of the results of tests of some wires cut from the endangered cables, which we have abstracted as follows:

Five pieces of wire were taken from cables A and B, over the saddles on the south side of the Manhattan tower at the point most exposed to the fire. These pieces were tested in the engineer's office, the results showing minimum and maximum strengths of 80,400 and 125,200 pounds per square inch respectively, the average being 98,040. One piece tested for elongation gave 2 1/10 per cent. in 50 inches.

These tests show that the breaking strength of these wires has been reduced about 50 per cent., and it is reported that lengths of about 10 feet will have to be replaced in some 250 wires in all, in the two cables on the south side of the tower, which were most exposed to the fire. As mentioned last week, all the wires in the cables are spliced on account of their great length; hence the ultimate weakening of the cables resulting from the repairs necessitated by the fire will be infinitesimal. About 100 men are employed in removing wreckage and it is expected that it will all be removed and the new platforms in readiness for resumption of work on the cables by December 1.

Anchor Ice accumulated around the inlet of the gate house at the New London, Conn., storage reservoir last January, in such quantities as to stop the passage of water, the screens being broken and the gate chamber blocked. Engineer W. H. Richards states that only by strenuous exertions was a supply maintained through the 16-inch pipe outside the chamber.

The Control of Non-Navigable Streams by the National Government.

A Discussion by Rudolph Hering at the Washington Convention of the American Society of Civil Engineers; reprinted from "Proceedings," August, p. 572.

This topic does not allude to the questions of diverting water from a water-shed, of silting up or of polluting streams; yet these are quite as important, and are pressing for solution. As they are also intimately connected with the damming and regulation of streams, it seems but natural that they should be considered in connection therewith, and the speaker accordingly takes the liberty to do so.

As civilization spreads over a country, changes take place in the physical character of the land surface by the decrease of forest areas and the corresponding increase of cultivated areas, allowing the soil to be more readily washed into watercourses, and, in populated centers, by the addition of surfaces more or less impervious to water. Changes take place also in the character of the water as it flows in the streams, and in the size and shape of the beds themselves.

The water when flowing is likely to change, both in quality and in the distribution of quantity. The more soils are exposed to washing by rain-water, the more soil particles will be brought into it, and carried in suspension by it, causing it to become more or less turbid. The sites of habitations and manufactories in city or country, and the application of manure to cultivate fields, cause every rain storm to bring into the streams organic matter which causes them to become more or less polluted, if not directly offensive, and injures the water, either for domestic consumption, for fish life or for manufacturing purposes.

The quantity of water flowing in a stream is changed by the growth of population in a way that flood flows tend to increase, and dry-weather flows tend to diminish. Flood heights increase by the reduction of forest areas and of water-retentive vegetation, which causes more rapid run-offs and greater velocity in the streams. Dry-weather flows decrease in consequence thereof, because there is less time for percolation into the ground, and therefore less storage of ground-water to feed the streams in time of drought. The use of water for irrigation purposes still further reduces the stream flow, both by direct diversion of the water and by evaporation on the surface of the land.

The beds of streams, so far as they are alluvial, change in accordance with the added amount of suspended matter carried by them, and also with greater floods and their consequent scour and re-deposit of material in lower stretches of the stream.

New causes therefore appear which tend to increase deposits when velocities become less, and to increase scour when these become greater. As both effects will not exactly compensate each other at the same points, the bed of an alluvial river is constantly undergoing changes, which have increased since the advent of civilized man.

Stream beds are still further and arbitrarily changed by man when he endeavors to develop the usefulness of the watercourse, and builds dams across it, either for slack-water navigation or for power and irrigation purposes; and again when he builds or fills material into the stream, or in some way encroaches upon its natural flood section, contracting it without attention to other consequences.

All these alterations in the original conditions of a stream become the more annoying, sometimes even disastrous, by causing other results than those desired, the more a community becomes settled and developed. The objectionable results are due, perhaps, to the higher floods which now destroy more developed property, perhaps to the lower dry-weather flows which deprive water users of some of their original ownership, and perhaps also to greater pollution of the water, tending toward unfitness for ordinary domestic, manufacturing or farming uses.

The multiplicity, as well as the seriousness, of effects upon large public and private interests caused by the streams both in their natural and artificial conditions, due to a large growth of population, is clear; some of the effects relate to sanitation, some to property rights for domestic, farming and power purposes, and some to commerce.

The National Government now controls the streams of our country, as far as they are navigable. It can regulate, dam and improve them for commerce alone. It has no control of the streams for the purposes of sanitation, irrigation or farming, for domestic and power supplies, or for any purpose of damming or contracting those that are non-navigable; nor, perhaps most important of all, has it control over the regulation of streams to prevent disaster from floods. And yet, in a developed community, these effects, while of small consequence in its early life, become of great consequence in its later life.

Reports are becoming more numerous of the ill effects of floods caused by the improper construction of dams or the change in the physical conditions upon the water-shed surface, of disasters caused by a narrowing of the flood channel or by accumulated deposit therein, or of polluted streams which have become injurious to the health and life of man and cattle.

The subject has become so aggravated in a few States that official bodies have been appointed and instructed to grapple with it in one or another of its phases.

State commissions will answer perfectly when the causes and effects are within the State. There is a clear difficulty, however, in having a single State endeavor to regulate the natural and artificial conditions of one of its rivers, when this originates in another State and is received in an injured condition, perhaps polluted, perhaps with its dry-weather flow seriously diminished or its floods increased. The other State may exhibit very little interest in the matter, and its legislature may decline to effect either the desired remedy or any remedy that had so far been suggested.

It is palpably unjust to a State, as it is to an individual, to permit a change to be made by one party to the injury of another, in the enjoyment of the natural privileges granted us by the land where we live, without a careful, impartial examination of the facts and an impartial solution of the difficulty.

While the United States Supreme Court is a proper final authority in many such cases, no court can ever be constructive, in a physical sense, and therefore will not answer the purpose now before us.

We need for this purpose in our country some Board or Commission of Waterways, which should have supreme authority over matters relating to the physical conditions of a river from its source to its mouth, irrespective of State boundaries, consistent with and resembling the authority already placed in national hands for regulating navigable streams for commerce; an authority which can make a thorough investigation into the physical conditions, not only collecting and applying information now in the hands of various public departments, but supplementing the same with local information of special value; to study the entire subject relating to floods and droughts, and pollution and diversion of the water; to establish official profiles and cross-sections for both dry-weather and flood conditions, to which all private interests should conform; and to establish limits for the pollution and diversion of water.

The engineering work of such a body would be considerable, yet the lines along which it should be undertaken would be clear, and the results like those of similar engineering enterprises. The organization of such a body, from a legal and political standpoint, is equally important, and is a factor, perhaps, more difficult of solution. It will not be touched upon here.

The programme of the topic under discussion asks whether non-navigable streams should be under the control of the National Government. In this opening the speaker desires to take a broader view, and would add: "or of Joint State Commissions, each one controlling the water-shed of at least one large stream?" The speaker does not in the least feel opposed to a control by the National Government; in many ways it would appear to be most satisfactory. There are also good and practical reasons for having, instead, a separate commission for each large water-shed, or group of smaller ones. A local commission would be better informed concerning local conditions, which are or may be highly important, than if most all of its members resided elsewhere. In either case, it would be desirable to place upon such a board a member of the United States Engineer Corps, and a member from each of the Departments of Agriculture, the Coast and Geodetic Survey, and, perhaps, also from a Bureau of Commerce.

It seems sufficient at this time to call attention to the importance of a proper regulation of our non-tidal streams, of the physical practicability of doing this, and of the necessity of having such regulation undertaken by a body whose authority must extend over the territory of at least one entire water-shed; our whole country being divided into as many water districts for this purpose as may seem best.

As precedents for such an undertaking we may consider the following:

The Mississippi River Commission is a body which has authority over the regulation of our largest river, extending through several States. Its authority, however, is less broad than it appears, from what was said above, might properly be given it.

Recently, a Flood Commission was established in the State of New York to report on flood preventions. The work of such a commission must be hampered to some extent by its limitations, and, unless it takes a broad view, and has authority and means to make comprehensive investigations and carry out recommendations, its usefulness to the State cannot be of the extent which is here contemplated.

In England, due partly to the more uniform and smaller rainfall and stream flows than ours, and partly to the previous attention that has been given to the question of damage by floods, these matters do not now receive very serious attention. The large industrial development, on the other hand, has compelled the enactment of laws for the government of streams, prohibiting the introduction into them of solid matter not carried in suspension, such as earth, ashes, building rubbish, sludge and solid sewage, also all liquid sewage and polluting liquid from manufactories, provided that remedies are reasonably practicable and available under the circumstances of the case. The carrying out of these laws is placed in the hands of River Conservancy Boards and Joint River Committees, each of which has control of one or more water-sheds, and in some matters acts in conjunction with the Local Government Board, which has general charge of such matters.

In France, for many years there has been a special bureau in the Department of Public Works called the Hydrometric and Flood Announcement Service (*Services Hydrométriques d' Annonce des Crues*). This bureau has studied the general conditions of each river basin, the means to prevent inundations and to regulate and equalize the flow, and sends advices when floods are expected. The water-sheds for which special Boards were instituted under the direction of the Chief Engineer of Bridges and Roads (*Ingénieur en Chef des Ponts et Chaussées*) are: Seine, Canal de la Sambre, Escault ét Yser, Rhône, Muerthe et Mosel, Aune, Téch et L'Agly, Garonne, Dordogne et Adour, and Loire. Among these, the Seine, Rhône, Garonne and Loire are the most important. Quite recently, a law has been passed authorizing the Department of Hygiene to inquire into the pollution of rivers, and provide remedies. It also authorizes the protection of all sources of water supply, and imposes fines for polluting the same.

In Germany, the regulation and correction of streams is in the hands of Provincial Governments in Prussia, and the State Government in Bavaria. The smaller states agree to the treatment of interstate rivers by the adjoining countries before work is done.

Each of the Prussian provinces has a Stream Building Commission (*Strombaudirection*), with a Chief Engineer (*Oberpraesident*) at its head, which controls design, construction and operation for each river flowing through several districts, and even into adjoining provinces, so as to obtain uniform results for the entire river. Such Commissions are located in Dantzic for the Vistula, in Breslau for the Oder, in Magdeburg for the Elbe, in Coblenz for the Rhine, in Munster for the Dortmund-Ems Canal, and in Potsdam for the Havel, Spree, Oder-Spree Canal, etc. The mouths of the rivers are controlled by another branch of the government, for political reasons. The rivers pollution questions are under the control of a Minister of the Government, advised by the Imperial Board of Health.

For information concerning European countries the speaker is indebted to Ernest Pontzen, Cor. M. Am. Soc. C. E.; Theodor G. Hoech, M. Am. Soc. C. E., and R. A. Tatton, M. Inst. C. E.

In some respects, it will seem better to have separate authorities to regulate the questions of quantity and quality of the water, speaking broadly. On the other hand, there are many intimate connections which point to a preference for a single commission controlling both hydraulic and sanitary questions. In Europe these questions are now in the hands of different bodies, both, however, branches of the general government.

With many of our larger rivers, flowing from one State into another, it seems proper and timely to obtain, as early as possible, a harmonious and intelligent treatment of their profiles and sections, and also of the questions of diverting and polluting their water. Official profiles should be established for the entire river, which will regulate the velocities, both at high and low stages, so that they will not cause disastrous results. Normal cross-sections should be established for the ordinary and also for the freshet flows. No obstructions whatever should be allowed within them, although the territory rarely flooded, but lying within the flood sections, might be used for agricultural purposes, as is sometimes done in Europe, with the risk of occasional destruction of crops. As it may often be necessary to protect wide expanses of adjoining property, some flood sections would have to be diked; and, to prevent interruption of the crossing traffic, the entire flood section between dikes would have to be bridged at the proper height. In many cases it would be advisable to alter the alignment of the stream more or less, to straighten and shorten it, where now there is meandering. In adapting such changes to the special soil of the bed, it is often also necessary to construct special submerged dams, so as to maintain the original and natural regimen of the streams.

An important duty would also be the establishment of storage reservoirs where found expedient, for the purpose of reducing flood discharges and increasing low-water flows, both of which may benefit the riparian owners by preventing damage in one case and ensuring greater usefulness in the other.

The diversion of a part of a stream should be regulated in such a manner that the water, in accordance with its value, could be properly and justly distributed among the respective States within its water-shed, and deprive no State of water to which it has a natural right.

Where works of industry, and particularly of ore-washing, load a stream with matter that is first carried in suspension and then deposited lower down, thus raising its bed, proper means should be proposed to prevent injury to any riparian rights without unjustly interfering with important industries.

And lastly, such an authority as above suggested could establish regulations regarding the pollution of water from source to mouth, and thus protect it for the benefit of all users alike, whether in one State or another. It would devolve upon the same authority to determine the proper uses to which the waters of certain rivers could be put. In some cases it would be practicable, and even necessary, to reserve them for the domestic supplies of future populations; in others, manufacturing interests may abound to such an extent that certain streams should not be devoted to domestic use, but reserved for other uses, and protected only to the extent of not becoming objectionable to sight or smell.

Regarding the important matter of payment for the work herein considered, it may only be said that whether the National Government or Joint State Commissions undertake the same, it would manifestly be unfair to pay for it entirely from funds of the General Government, in districts where it is not itself a large landowner, because the benefit would accrue generally to the water-shed affected, and particularly to the riparian property owners. Payment, either by the State at large within which the improvement is made, or by the assessment of benefits against the counties or the private individuals affected, would seem more equitable.

All the subjects here suggested, and but briefly touched upon, are more or less effectively solved in the countries of Western Europe. They are now becoming more and more urgent of solution in our own country. It is to be hoped that we will not be long in arrears in crystallizing the method of handling this important subject in non-tidal streams as well as it has been handled in tidal rivers, in part by the United States Corps of Engineers, and that the results may be at least as beneficent as those accomplished across the Atlantic.

Shortening the Working Day to conform to the eight-hour law will increase the cost of the work remaining to be done under the contract for the New Croton Dam, New York, it is estimated, $305,000, the contract having been based upon a ten-hour day.

A Letter to the Editor.

Residential Septic Tanks.

Sir: It was with much regret that the writer was unable to attend the Rochester meeting of the American Society of Municipal Improvements so that he might have a part in the interesting and profitable discussion of the paper which was to have been read there on the above subject, but it is gratifying to know that some points have been brought forth in the excellent letter of Mr. Benjamin H. Flynn, Columbus, Ohio, published in your issue of October 25th, which brings out the economics involved in the universal installation of such residential septic tanks as were described in the writer's paper.

We are free to admit that perhaps the weakest point in the whole proposition is the difference between the combined cost of the residential tanks and the cost of a municipal septic tank plant of the same capacity. We hinted at the possibility of obtaining sufficient purification of the effluent of the residential septic tanks during the flow through the open channels in the low, flat district between the outlet of our sewers and Lake Michigan, a distance of about ¾ mile. The land where the city proper is now being built lies at an elevation of from 30 to 100 feet above the low territory, and if necessity for a municipal plant should arise, it might be met by converting these open drains into irregular ditches and using the effluent for irrigation purposes upon the land which these open drains intersect, or by creating bacteria beds, which have been so successfully installed and operated in England and elsewhere. The unpurified effluents could, also, be combined and taken to the southward a distance of one mile and emptied into a low, wet territory, from which a dead river finds an outlet into the lake some two miles beyond. Municipal purification works could be obviated by one of these four possibilities. The initial installation of residential septic tanks at Zion City seems to have been a growth rather than the result of enactment, as the original article stated. Farm drains were available, and some kind of sewerage privilege was everywhere demanded, but only in places where these drains were available could any sewerage privileges be had. The excellent results we had obtained with our own residential septic tanks, during a period of twelve years, led us at once to institute the building of tanks which are but little more than ordinary catch-basins in construction, wherein the solid matters of the house wastes could be converted at least into fluids. This would produce an effluent which common farm tile with slight grades could care for without much possibility of choking up. Residents everywhere were willing to do anything that would enable them to obtain these privileges, which privileges the very laws of good health would prevent any capable person from granting except where good health and cleanliness would not be impaired. In further support of the construction of these septic tanks as far as cost is concerned, it may be said that the work done in Zion City seems to be but a step in advance of what Mr. Flynn suggests in his example of the scheme adopted at Bowling Green. If the catch-basins at Bowling Green are not constructed upon a plan which will conduce to septic action within, then the cost to that city or any city adopting such a scheme, would be an almost total loss in view of the fact that a purification plant must be built eventually. The cost of the residential tank is but little greater than that of the ordinary catch-basin and it is but a slight modification of the catch-basin, so constructed as to induce the desired septic action and to pass an effluent free from adhesive solid. Hence we believe we have improved upon the suggestion as exampled by the Bowling Green scheme in that we are making the catch-basin something more than a catch-basin and making it so permanently. We also propose, instead of drawing upon the future water system for a supply for flush tanks at the dead ends of such laterals as would require them, to collect the daily discharges of the future residences at the upper ends of such laterals into a single flush tank, which would empty as often as the combined wastes would fill it, thus effecting a saving in water consumption.

To the average citizen special taxation is odious and he would willingly expend a few more dollars upon his premises for something that would become all his own than to pay his money into the public treasury and become a co-partner in a large unprofitable plant, as it would doubtless seem to him, quite beyond his personal control. Why should the householder raise any objection to building a residential septic tank, on this simple pattern, when in all probability he would have a catch-basin to construct anyhow? The objection raised because of the possibility of misconstruction can be raised against any part of the sewerage system, and we do not see why so simple a tank cannot be well made. Common brick, Portland cement mortar, two vitrified pipe elbows, a common white-wash brush to do the interior coating with, and almost any kind of a top make the sum total of the materials needed. It is not more necessary to make the tanks water-tight than to make the sewers water-tight. Careful, conscientious workmen will do this in either case and careless workmen probably would not. If the masonry of the tank should not be as thoroughly constructed as it ought to be, much possible leakage is easily prevented with a four coat wash of Portland cement on the inside.

As to the occasional cleansing, we hope to be able in the very near future to so perfectly gauge the size of these tanks to the requirements that cleansing would be infrequent; and construction could be introduced which would permit the entire drainage from the house roof to be occasionally turned into the tank so as to stir up a large amount of sludge that might have collected in the bottom and cause it to pass off. We do not see why these tanks cannot be made equally effective in septic action to a tank, with two filter bed purifiers, recently referred to by a well known engineer who found that 95 per cent. of the solids which had passed into the tank in one year had been converted into an effluent which, after the second filtration, was pure enough to be drunk by the workmen about the premises. If, for any reason, the sewer connection to any residence should get out of order, the incentive to the ordinary individual would be sufficient to induce him to put such part of his sewer service into as good condition as he is able without the aid of the plumber, and, as in the case of the cleansing of the septic tanks, it need not take more than 15 or 20 minutes, judging by our personal experience, once every three or four years. Very respectfully,

Burton J. Ashley,
City Engineer.

Zion City, Ill., November 10.

Sanitary Inspection at Charleston, S. C., is done by four men appointed annually by the Board of Health. They are required to examine fifty premises a day, and as proof of inspection, obtain the signatures of the occupants. They are required to examine into the sanitary condition of the yards, and report as to the condition of the privy vaults and drains, and see that all garbage has been removed and that the premises are in good condition. They have also to keep a watch on the 17 hydrants, placed about the city in convenient localities, where the poor may obtain water.

Sea Mills Sewage Disposal Works, Near Bristol, England.

The Sea Mills sewage disposal works were designed to replace a sewage farm that had become insufficient and was badly situated for the accommodation of recent building extensions, and also to treat the sewage from Stoke Bishop that formerly ran direct into the River Avon. The works are placed in a narrow valley about ¼ mile from the River Avon. They are designed to accommodate a population of 10,000, the present population being nearly 7,000, and are so arranged that extensions upon the same lines may be made up to a population of 30,000.

The effluent discharges by a brick culvert, 3 feet 6 inches by 2 feet 4 inches internal dimensions, into the tidal portion of the River Avon at a point below low water, but the Local Government Board, in giving their saction, required the discharge to be only between high tide and an hour and a half before low tide. They stipulated that the sewage should be capable of being treated with chemicals, and after such treatment, together with subsidence in tanks, should be stored, except during the hours above stated. The method of automatically regulating the flow from the storage tank is especially interesting, and is brought out in a paper by Mr. A. P. I. Cotterell, Assoc. M. Inst. C. E., in a recent issue of "The Surveyor," from which the following description of the works has been condensed:

The 24-inch sewer from Westbury and the 18-inch sewer from Stoke Bishop, which is carried across the valley on an aqueduct, join at a gauging chamber, where brass plates indicate at any moment the rate of flow through either sewer in gallons per minute and gallons per hour. Immediately after junction the sewage flows through a revolving screen of large mesh automatically driven by a water-wheel, the sewage itself being used as a motive power.

Provision is made for the addition of a precipitant to the sewage before passing over the water-wheel, so that thorough mixing may take place. The liquid thence flows into two grit chambers, placed underneath the engine-house floor. The grit chambers are formed with tapered sides and a discharge valve at the bottom, so that all sludge or grit can be forced into a sludge tank placed underneath the press-house without emptying the chamber. To assist in the disposition of the sludge, and to keep the sides of the grit chambers clean, a large number of nozzles are arranged in rings, through which air or water can be discharged under pressure, and thus sweep the whole of the chambers clear of all deposit.

From the grit chambers the sewage passes through a distributing channel, and thence into three covered tanks, each 171x12 feet in size, capable of being used for subsidence or for anærobic action. The clarified effluent from the septic tanks passes off in the usual way through a slotted pipe, and thence down a slide into the large covered storage tank, which is capable of holding 600,000 imperial gallons. The discharge from this tank into the brick culvert is controlled by a hydraulic penstock, 36 inches in diameter, worked automatically by a tidal clock, and so arranged that a final effluent is discharged into the Avon during the hours when such may be allowed.

In the septic tanks are large V-shaped scrapers, which can be made to work slowly on an endless rope throughout the tank and draw off any sludge or debris into a V-shaped discharge notch at one end, whence it passes into a sludge chamber without emptying the tanks. Both sludge chambers are provided with floating arms, for drawing off supernatant water and also with suction pipes connected with the sludge ram, from which the sludge is forced into a 27-inch square Johnson's sludge-press containing twenty-four chambers.

The clock controlling the automatic discharge is the joint invention of Mr. A. M. Hunt and Messrs. Kemp Brothers on suggestions made by Mr. Cotterell. It is designed upon the alarm principle, with five faces, and is so arranged that it actuates the penstock both for opening and closing twice every day. The hydraulic accumulator contains sufficient water for four actions of the penstock. It is charged each day by the attendant, who at the same time sets the clock for the two tide discharges of the day, and has no further trouble about this part of the works. The periods of discharge are adjusted to correspond as closely as possible with the periods on the tide table. By means of this clock, which cost less than $750, there is no need of a night staff, the discharge taking place with even greater regularity than the most efficient manual labor would probably afford.

Computation of the Stability of High Chimneys.

Recently the Prussian Minister of Public Works has acted on a recommendation of the Prussian Building Academy and has issued a set of regulations governing the design of high chimneys. As reported by the "Deutsche Bauzeitung," these regulations are essentially as follows:

The regulations generally prescribe an assumed wind pressure of about 26 pounds per square foot on a plane perpendicular to the direction of the wind. Any possible suction on the leeward side is assumed to be included in this pressure. The wind area of the chimney is taken to be its vertical section, and, if the chimney is polygonal, its greatest diametral section is to be used. The point of application of the resultant of the wind pressure is to be assumed to coincide with the center of gravity of the section, which is equivalent to assuming a uniform distribution of the wind pressure over the full height of the chimney. For circular chimneys the total wind pressure area is to be reduced to two-thirds, and, for octagonal chimneys to .71 of the value for rectangular chimneys.

To determine the greatest pressure at the edges the wind should be assumed to act in a diagonal direction. The specifications allow the theoretical opening of the joints to the center of gravity of the section, thus neglecting the tensile stresses. The compressive stresses should be determined for wind pressures of 26 and 31 pounds per square foot. The weight of the material per unit of volume should be that of the actual material used. The allowable unit stresses were fixed as follows: For common brick-work laid in lime mortar (1:3), 100 pounds per square inch; for hard burnt bricks, having a compressive strength of at least 3,160 pounds per square inch, laid in cement-lime mortar (1 cement, 2 lime, 6 to 8 sand), 171 to 214 pounds per square inch. For the stronger stones and mortar richer in cement, higher stresses are allowable, but a factor of safety of 10 must always be provided for, and in no case should the greatest pressure exceed 316 pounds per square inch for a wind pressure of 26 pounds per square foot. If higher unit stresses be deemed allowable, they should be justified by tests on blocks of masonry. The allowable compressive stress on the foundation is, for unrammed concrete, 85 to 114, and, for rammed concrete, 142 to 214 pounds per square foot. The allowable bearing pressure on the soil for the assumption of 26 to 31 pounds per square foot wind pressure is, as a rule, 61 pounds and, exceptionally, 82 pounds per square inch, equal respectively to very nearly 4½ and 6 tons per square foot.

Ventilation in the Pratt Institute High School, Brooklyn, N. Y.

An interesting example of a method of providing improved facilities for ventilation in an existing building without necessitating much reconstructon is afforded in the high-school building of Pratt Institute, on Ryerson Street, Brooklyn, N. Y. The original arrangements for supplying and distributing air were found to be inadequate. They comprised the delivery of air into the building by means of a fan which, located in the top story, discharged through a central shaft and by setting up a plenum pressure was depended on to force an outflow through windows, doors and other points of egress. The problem involved the establishment of a more extended system of fresh-air distributing passages and the provision of special openings for the vitiated air, without resorting to the expense of constructing vertical flues throughout the building. The accompanying drawings will show how the work was done, which was proportioned on more generous proportions than usual in schoolhouse work.

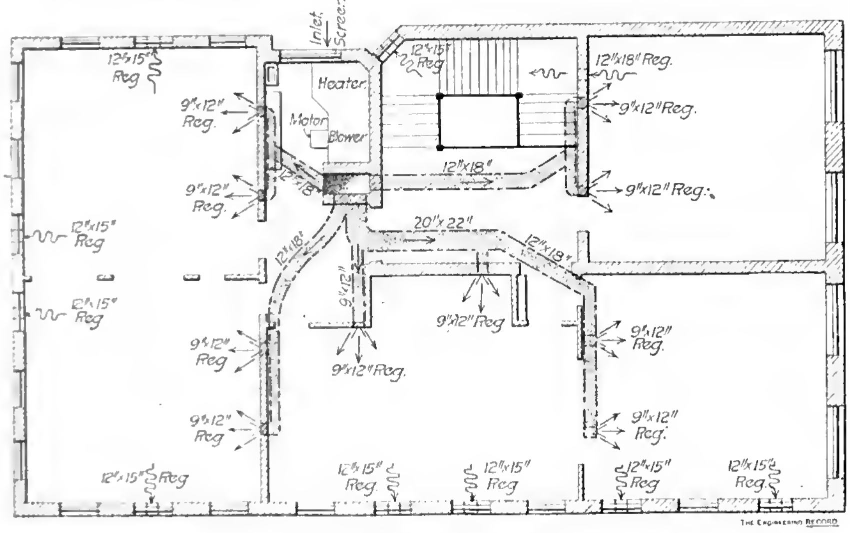
The building was erected in 1890 to provide recitation rooms, a director's office and a small gymnasium for the technical high school department. Its three stories and basement, covering a ground area of 3,700 square feet, are sufficient for these purposes, as all laboratories and shops are in the main Institute building. As originally constructed one fan was installed in a small room on the third floor and connected to a single shaft, about 2x4 feet in area, with openings on each floor, from which the fan exhausted the impure air. The fresh air was not given any special inlet but was left to enter through windows, doors and by general leakage. It was found impossible, however, to get a proper amount without opening the windows which sometimes caused discomfort to the pupils in the winter.

The next scheme was the reversal of the first; the fan was driven in the opposite direction so as to force fresh air down the shaft to the various floors and heater coils were installed to temper the air on its admission. This plan proved to be an improvement over the first, because the windows could usually be opened wider with less danger than before. Nevertheless, the great distance of some of the rooms from the shaft and the direction of the air outside often made it impossible to open some of the windows without an inrush of cold air, and generally speaking the building was without a positive system, offering at all points the desired degree of ventilation.

During the last year it was decided that the old plant must be completely revised and a modern system installed. This work of reconstruction was done during the last summer. The same air shaft has been used and it is fortunately well located so that it affords an excellent center of distribution. At the second floor a horizontal diaphragm has been placed in the shaft to divide it into two parts. Through the upper half, the old fan supplies the second and third floors; and through the lower half, a new fan installed in the basement supplies that floor and the first floor. If one fan should become disabled, an opening in this diaphragm will permit the other fan to supply the entire building. Both fans may be run faster than their normal speed, so that either can temporarily supply the entire building.

The new fan is a steel-plate blower, manufactured by the B. F. Sturtevant Company, of Boston. It has a wheel 60 inches in diameter, running at 300 revolutions per minute and capable of discharging 15,000 cubic feet of air per minute. It is direct-connected to a General Electric motor of 7½ horse-power. The heater is roughly 6½ feet high, 4 feet wide and 3 feet deep and consists of three sections of 1-inch pipe with a total heating surface of 550 square feet. The section first encountered by the entering air is controlled by a thermostatic valve which is opened when the temperature of the outside air falls below 35 degrees Fahrenheit. The other two sections are supplied under the control of a thermostatic valve which is governed by the temperature of the air leaving the heater and is designed to maintain that temperature at about 70 degrees. The thermostatic valves are operated on the Johnson system. Beyond this valve the pipe branches to the two sections and each branch contains a hand valve to open or close that section to steam at will. The steam is supplied through the regular Institute heating system, which is operated with a vacuum of about 10 inches on the air valves and uses the exhaust of the engines. All condensation is returned as feed to the boilers.

The old fan on the third floor is also of Sturtevant make, has a 48-inch wheel and a capacity of 6,400 cubic feet at 250 revolutions per minute, and is direct-connected to a 3½-horse-power General Electric motor. The heater for this system is supplied with steam and dripped in the same manner as is the other heater. The air is tempered with thermostatic valve regulation to abont 70 degrees and is found to reach the most distant rooms with practically no loss in temperature.



Plan of Third Floor.

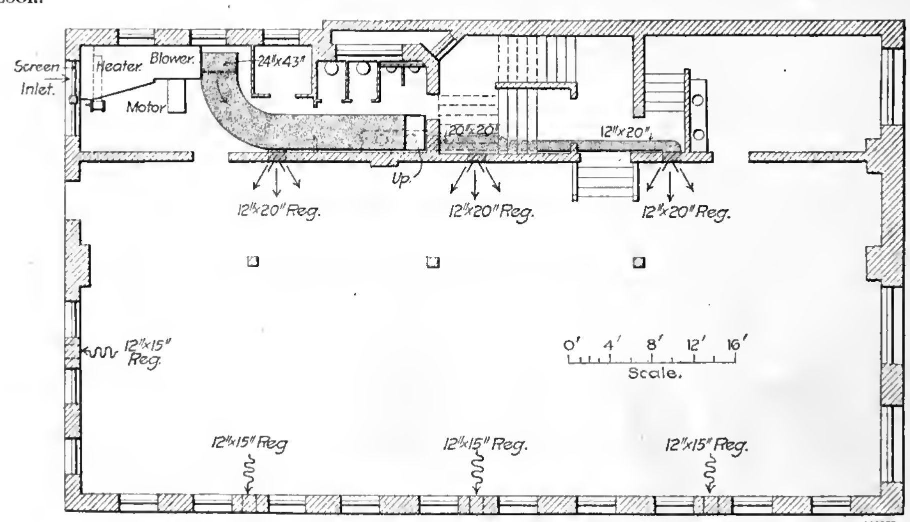
The arrangement of the ducts and the location of the registers for the ventilation of the first, second and third floors are practically identical to those shown on the third floor plan. The air inlets to each room are about 9 feet from the floor and are located in the side nearest to the main air shaft, so that the ducts are as short as possible. The class rooms have in general, two inlet registers each, which, to diffuse the air to all parts of the room, are provided with deflector plates set at an angle of 60 or 45 degrees with each other, according to the distance to the opposite wall. The air outlets are the same in number but have an area about 50 per cent. greater than the inlets and are located in most cases under windows. These outlets are of special construction, as shown in the accompanying perspective sketch. On the inner face of the wall there is an ordinary cast-iron register, on the back of which are hung four or five horizontal overlapping flaps of rubber cloth. These separate only when the pressure within the room exceeds that without and thus prevent a back draft of cold air from the outside. When the pressure condition is the reverse, a wire screen beyond the register limits the outward swing of the flaps and obviates their becoming disarranged. The opening is protected from rain on the outside by a hood having a wire screen across the opening in its lower side for the purpose of keeping birds or debris from getting inside and choking it up.

Where possible the rooms have outlets in two sides, with the exception of the front rooms. Here, rather than deface the front of the building, the exits are placed in the side wall or into the stair well, as the plan of the third floor indicates, the stair well itself having in that case an outside vent opening.

The horizontal ducts connecting the registers with the main air shaft have been concealed in the ceiling space so that the drop legs to the registers form the only visible part of the piping. These have been neatly designed so as not to render their exposure objectionable.

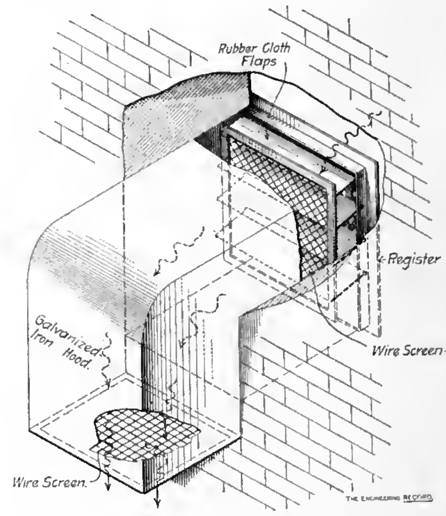
The velocity of the air into the rooms is calculated to be about 500 feet per minute, but is reduced, where it leaves the room, by using outlets which are larger than the inlets, to prevent injurious drafts on the occupants near these points. It is intended to change the air of the rooms once in every 10 minutes with an average allowance of 3,000 cubic feet of air per hour per person.

The basement ventilation is particularly simple, as shown on the plan of the basement. The fresh air is admitted at one side of the single large room through three registers, each having an opening of 240 square inches area and located 9 feet above the floor. One of these is taken directly from the large duct connecting the fan and the air shaft, the other two are supplied through a small branch duct from the main shaft. The air outlets are four in number, 12x15 inches each, so that their combined area is 760 square inches, that is 40 square inches more than the combined area of the inlet openings. The velocity of the outgoing air is, therefore, practically equal to that of the entering air and is allowed in this case because in the ordinary usage of the room no one sits near the outlets.



Basement Plan.

The entire system was designed by Mr. Joseph Foster, the chief engineer of Pratt Institute, and was installed under his direction.



Detail of an Air Outlet.

The galvanized iron work was made and erected by Mr. William Spencer, of Brooklyn.

A Foggy Weather Signaling System in connection with the block system of railway operating, that might be adopted to great advantage in the United States is used in Great Britain by the North-Eastern Railway Co. The following brief description of this system was sent from Edinburgh by a correspondent of The Engineering Record: At both the distance and the home signals there is, in addition to the semaphore arm, a part that is set simultaneously with the arm. When the semaphore is set at danger, the auxiliary part is brought into position for striking and knocking backward a lever on the engine. This lever, when knocked backward or down, sets a whistle to blowing in the cab. The engine driver is thus warned of a train on the block although unable to see the sight signal; and not only is the driver warned, but the guard as well, which is a point not to be lost sight of in view of sudden sickness or incapacity of the engineer. The apparatus can be simply made and readily applied. Fogs occur with sufficient frequency in some parts of the United States to warrant the adoption of such a device; and tunnel and subway accidents might be obviated by its use.

The Circular Dam at Lake Cochituate.

By Charles W. Sherman, Assoc. M. Am. Soc. C. E., Division Engineer, Metropolitan Water Works, Boston.

At the southern end of Lake Cochituate, the original source of Boston's water supply, and from which something like 15 per cent. of the water for the Metropolitan Water District is still taken, is an area of shallow water covering about 80 acres, known as the "Peat Meadows." This is now a part of the lake, but more than sixty years ago, before the water had been raised by dams, there were at this place meadows whose surface was but slightly above the water in the lake. By successive raisings of the lake, made first by owners of mills upon the outlet, and later by the Boston Water-Works, the elevation of high water was raised 7 feet, so that when the lake was full there was a depth of 5 or 6 feet over the meadows.

More than half of the total watershed of Lake Cochituate is tributary through these meadows, which, it should be noted, are divided from the lake by the Central Turnpike and by the embankment of the Boston and Albany Railroad. Realizing that water over "shallow flowage" deteriorates and that the meadows were unsightly, if, indeed, not prejudicial to health, when exposed by the annual drawing down of the lake, the Boston Water Board constructed a regulating dam at the point where the water flows under the Central Turnpike. This dam, a view of which is shown in the accompanying

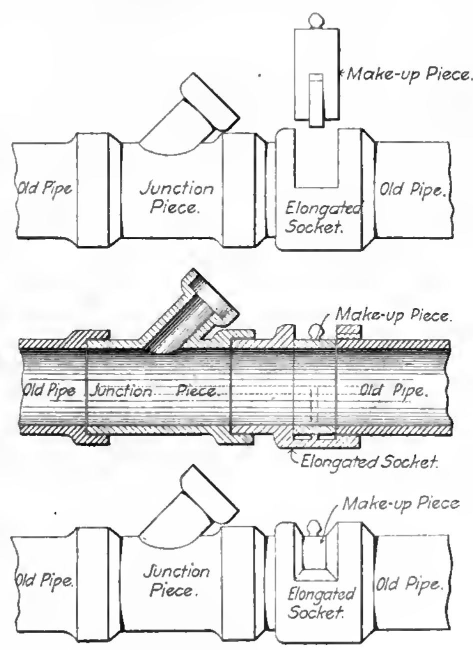
Circular Dam, Lake Cochituate.

illustration, was built in 1879, and is semi-circular in plan, in order to obtain a great length of overfall and thus avoid backing the water up too high. It has a core wall of 6-inch tongued and grooved sheeting, driven on a circle of 30 feet radius. On the upstream side the sheeting is backed with gravel, having a slope of 2 to 1; while the downstream side is filled with stone, heavily paved on the surface. A sluice 6½ feet wide was built through the dam, containing stop-planks by which the water may be retained at any desired height. When the water stands at high-water level, the dam is entirely submerged, but when the lake is drawn down the dam retains the water upon the meadows, as shown in the view.

This dam was the forerunner of the circular regulating dam in Sudbury Reservoir, built in 1896 by the Metropolitan Water Board. This latter dam is nearly a complete circle in plan, leaving only a sufficient opening for the culvert through the road embankment which retains the water. Both of these dams were built under the direction of Mr. Desmond FitzGerald, M. Am. Soc. C. E., who was superintendent of the Western Division of the Boston Water Works when the dam at Lake Cochituate was built, and who is now engineer of the Sudbury Department, Metropolitan Waterworks. Mr. F. P. Stearns, M. Am. Soc. C. E., is chief engineer of the Metropolitan Water Works.

A Device for Inserting Lengths of Pipe in an Old Drain.

A patent device for inserting junctions or new lengths of pipe in an old drain or pipe sewer was described recently at a meeting of the Incorporated Association of Municipal and County Engineers, by its inventor, Mr. H. J. Weaver, borough surveyor of King's Lynn, England. According to the report of the meeting published in "The Surveyor," the device consists of a short length of ordinary pipe or a junction, as the case may be, and a short piece of special deep socket pipe in which a slot is cut half-way round, giving room for the insertion or withdrawal of the specially prepared ring of pipe, or making-up piece. The method of setting is as follows: The old pipe in the sewer where the junction, or Y branch, is required to be fixed is broken and taken clear away, and the earth removed for a distance back of about 6 inches, all round the spigot-end of the old sewer pipe in order that the elongated socket may be telescoped on it as far as it will go. This having been done and the socket telescoped as directed, the junction piece is next fixed in position, the spigot-end of the elongated collar is drawn into the collar of the junction pipe, and the whole operation completed by inserting the ring, or



Patent Insertion Pipe.

making-up piece, into the slot provided in the elongated collar. In the case of a blocked drain or sewer the pipe is invaluable. It is made without the junction, for which is substituted a piece of straight pipe, and is strongly recommended for making good the drain or sewer after it has been cleared. By this method it is only necessary to break and remove one pipe, and the usual risks of broken collars, improper gradients and leaky joints are entirely obviated. A true invert is obtained all through by pieces which are made inside the deep socket to receive the spigot-end of pipe, and also a piece on the bottom side of the ring. The joints can then be made good with cement or clay, so as to be reliable and watertight. The arrangement is adaptable to replace either 2 or 2½-foot pipes in the sewer by the simple alteration of length in the junction piece, and has been found in practice to work admirably.

Personal and Obituary Notes.

Mr. J. F. Kieser has been elected superintendent of public works of Little Rock, Ark.

Mr. Gerald S. Griffin has been appointed assistant engineer to the Aqueduct Commission of New York City and Mr. Clifford B. Moore, transitman.

Mr. A. S. Tuttle, M. Am. Soc. C. E., read a paper on engineering work in Hawaii before the Brooklyn Engineers' Club, November 13, illustrated by lantern views.

Mr. Louis Hatch has been appointed city surveyor of Wilmington, N. C., Major W. F. Robertson, whose appointment was noted last week, having decided not to accept.

Lieut.-Colonel William R. Livermore, Corps of Engineers, U. S. A., has been directed to proceed to Ft. Monroe, Va., to prepare for taking part in the West Indian naval manoeuvres.

Daniel Pratt, for over 50 years actively engaged in civil engineering, died November 17 at Uxbridge, Mass., aged 82 years. He was first employed in construction work for the Norwich & Worcester Railroad in 1839.

Lieut. Andrew L. Harrison, a retired chief engineer of the U. S. Navy, died at his home near Bristol, Conn., November 16. He was born in 1829 in Southington, Conn., and was retired from the Navy in 1894 after 35 years' service, commencing when the Civil War broke out.

Prof. J. H. Kinealy, formerly professor of mechanical engineering at Washington University, and Mr. Andrew G. Paul, formerly of the Paul Steam System Co., have organized the Paul-Kinealy Co., Pemberton Building, Boston, for the practice of engineering in power, heating, ventilating and drying work.

The Cienfuegos, Cuba, Municipal Council has authorized Mr. H. J. Reilly, Jr., of New York, to prepare plans and specifications for a system of water-works and sewers, which, it has been estimated, will cost about $4,000,000.

A Civil Service Examination for Topographical Draughtsmen, first to fourth grades, salary not exceeding $1,200, will be held at 10 A. M., Thursday, December 11, at 61 Elm Street, New York City, as advertised in another column of this issue.

Public Buildings, the more pretentious private edifices and other structures of architectural worth may be so located, correlated and grouped as greatly to enhance the beauty and dignity of the *ensemble* effect of a municipality or of an individual street, if skilful oversight be given to the esthetic element in the appearance of the community. The value of such structures, however, as means of municipal adornment, is all too frequently wasted, partly from lack of appreciation, false ideas of economy and civic indifference. The sentences quoted below from the presidential address of Mr. Ashton Webb, at a recent meeting of the Royal Institute of British Architects, seem to apply with equal force to the conditions obtaining in America. "The Government is largely engaged in the erection of public buildings; local authorities all over the country are busy with the erection of town halls, asylums, schools, technical institutions, etc., while the buildings, residential and commercial, in our great towns continue to increase at almost an alarming rate. What, I think, must strike most of us in all this activity is that while minute control is exercised by public authorities over the details of these buildings, such little control is exercised over the laying out of our cities that, to a great extent, they seem to be left to lay out themselves. How often we see a really noble and costly building hidden away in some inconvenient and cramped site, without any approaches worthy of the name, simply because the land was easily obtainable or happened to be vacant at the time, or could be obtained cheaply, or to improve the value of adjoining property; reasons we have heard put forward repeatedly, but nearly always resulting in the loss of a great opportunity of ennobling and beautifying the town; while, instead of money being saved, as is foolishly supposed, money is really wasted and thrown away."

The Storage of the Water from the Thames and Lea Rivers is considered to be of much importance in improving the quality of the London water supply, according to the annual report of the Local Government Board. Commenting on this report "The Surveyor" says: Dr. Thorpe, the analyst, admits that under ideal conditions the use of water subject to such regular pollution as that indicated by the presence of organic matter in the raw Thames and Lea waters would be avoided; but he discounts this admission by the general conclusion that, given the exclusion of certain flood waters and the provision of proper storage and filtration, the risk to public health is reduced to a minimum, if not to zero. Certainly it must be admitted, even by those who, on various grounds, support the introduction of a long-distance supply, that the practical immunity of London from anything that can be regarded as a water-borne epidemic gives strong support to the conclusion. It is pointed out that the organic matter present in the Thames and Lea waters, as delivered to the metropolis after storage and filtration, is to a relatively large extent of vegetable origin; and in this connection attention is drawn to the importance of storage reservoirs, especially when the rivers are in bad condition. It would appear that, generally speaking, the companies which last year delivered the best water were those having the greatest storage capacity.

The Pierce County Improvement Company is about to commence the improvement of one of the largest water powers on the Pacific coast. The scheme contemplates the use of power to be derived from the Puyallup River, which has its origin in the glacier of Mount Ranier, State of Washington, and flowing northwest empties into Puget Sound near Tacoma. A dam will be thrown across the river, the water diverted and carried by flume and ditch a distance of 10¼ miles to a forebay, from which will be taken steel pipes leading to the power house, and giving a net head on the wheels of 850 feet. The present development will be for 20,000 horse power. The flume will be built with a section 8 feet wide by 5 feet high, the height to be increased later to 7 feet to provide for the ultimate development of the plant. The ditch will be slightly larger. The forebay will be not less than 500x300 feet and 14 feet deep, holding water enough to carry the full load of the plant for two hours. The design providing for the location of the storage pond above the station eliminates chance of interruption to the operation of the plant by reason of accident to the flume. Two steel pipe lines, approximately 1,700 feet long, will convey the water to the power station, which will be of brick and will contain four impulse wheels, each directly connected to a 3,500-kilowatt generator. Alternating current will be generated at 2,300 volts, stepped up to 40,000 to 50,000 volts, and then transmitted to the cities of Tacoma and Seattle, distances respectively of approximately 30 miles and 40 miles from the power station. The very latest improvements in hydraulic and electrical engineering will be embodied in the new plant. Plans and specifications for the work are well under way, and contracts for the electrical apparatus will be awarded within a week. Men are now in the field making necessary locations and surveys. It is hoped that the plant will be in operation shortly after the first of January, 1904. We are indebted for the above information to Messrs. Stone & Webster, of Boston, who are the engineers for the project.

CONTRACTING NEWS

OF SPECIAL INTEREST TO

CONTRACTORS, BUILDERS, ENGINEERS AND MANUFACTURERS

OF ENGINEERING AND BUILDING SUPPLIES.

For Proposals see pages xv, xviii and xxvii.

WATER.

Brockton, Mass.—City Engr. Chas. R. Felton writes that the following bids were opened by the Water Comrs. on Nov. 8, for furnishing and erecting complete, on foundations furnished by the city in an engine house to be provided, 1 vertical, triple expansion, condensing, crank and fly wheel pumping engine of 6,000,000 gal. daily capacity, 150,000,000 foot pounds duty, to work against a 350-ft. head: Kilby Mfg. Co., Cleveland, O., $40,800; Barr Pumping Engine Co., Philadelphia, Pa., $43,500; Holly Mfg. Co., Lockport, N. Y., $43,800 and $35,200 short stroke; Snow Steam Pump Wks., New York City, $45,093; R. D. Wood & Co., Philadelphia, $62,000; Allis-Chalmers Co., Chicago, Ill., $64,000, and $68,000 for self-contained type.

Norwalk, Conn.—City Engr. C. N. Wood writes under date of Nov. 18 that a city meeting had been called for Nov. 21 to see if the citizens are in favor of laying a 16-in. supply main from Grupe storage reservoir, in New Canaan, to the distributing reservoir in Norwalk, at an approximate cost of $75,000.

Waterbury, Conn.—Property owners have petitioned the Bd. of Aldermen to provide a high service supply of potable water.

An appropriation is reported to have been asked for the purchase of meters.

Haydenville, Mass.—At a citizens' meeting held Nov. 16 the Joseph Wright brook was considered as a possible source of water supply for Haydenville and Williamsburg. Estimated cost, $35,000.

Dover, Me.—The Dover and Foxcroft Fire Dist. has taken the works of the Main Water Co. at Dover and Foxcroft, the appraisal of which by Comrs. appointed by the Supreme Court of Maine, was $135,600. A new reservoir and additional pipe lines are proposed. The present pipe system is 8.87 miles in length, composed of 10, 8, 6 and 2-in. pipe, with 35 hydrants all on 6-in. lines or larger.

Worcester, Mass.—Plans for the dam to be constructed by this city on the site of the Mann reservoir on Kettle Brook, in Leicester, have been filed with the County Comrs. by City Engr. Frederick A. McClure. The dam is to be built at a cost of $120,000.

Wilmington, Del.—A correspondent writes that the Water Dept. will proceed at once to have plans prepared for the construction of a reservoir which will probably contain about 200,000,000 gal., and also provide for filtering this supply.

Saratoga Springs, N. Y.—Bids will be received Nov. 25 by the Village Sewer, Water and Street Comn. for $40,000 water and sewer bonds. H. F. Thomas, Clk. of said Comn.

Schenectady, N. Y.—City Clk. Alex. Femirek writes that it is expected to lay a quantity of water mains in the near future. Chas. Trumbull, Engr. in Charge.

Penngrove, N. J.—John P. Leap, Chmn. of Water Com. writes that no contracts for water works or electric lighting (bids opened Nov. 12), have been given out, and that it is proposed to increase the appropriation for said work.

Brooklyn, N. Y.—The Bd. of Aldermen has authorized the expenditure of $48,000 for the construction of 2 new pumping stations at Greenpoint.

North Hempstead, L. I., N. Y.—The Town Bd. has established the Port Washington water supply district and bids will probably soon be asked for the furnishing of not less than 40 fire hydrants; new bids will be asked by said Bd. for the Great Neck water supply district.

Atlantic City, N. J.—The Water Comrs. are considering the question of recommending to Council the building of a filtration plant at the main entrance near Absecon.

Bayonne, N. J.—The City Council has sold $22,000 water bonds.

Pittsburg, Pa.—The Council on Nov. 17 passed an order appropriating $215,000 for water pipe extensions in the downtown district.

Rochester, N. Y.—According to local press reports the Rochester & Lake Ontario Water Co., which is to be incorporated at once, proposes to construct a system of water works, the pumping station to be located at Greenleaf farm; an intake pipe will take water from Lake Ontario, 3,500 ft. from the shore, water to be piped in 20-in. mains along the N. Y. C. R. R. to the factory district. Capacity of pumping engines to be installed 8,000,000 gal. per day; proposed reservoir to have a capacity of 8,000,000 gal. S. Q. Mingle, of Phila., Engr. in Charge. Geo. K. M. Clark, of Buffalo, is said to be promoter.

Troy, N. Y.—The Jefferson Water Works Co. has increased its capital stock from $3,000 to $15,000. Among the stockholders are H. Avery, H. D. Vaughn and Chas. Nichols.

Atlanta, Ga.—The bill which provides for an election looking to the issue of $800,000 bonds by this city for the improvement of the water works and sewerage system, has been passed by the House of Representatives.

Arcadia, Fla.—This city is reported to have voted affirmatively on the proposition to issue $20,000 bonds for the construction of water works.

Tocco, Ga.—This town is said to be considering the construction of a system of water works.

Richmond, Va.—The Water & Finance Com. has recommended to the City Council the issuance of bonds to the amount of $405,000, $350,000 of which is to be used in the construction of a settling basin and the balance placed to the credit of the Auditor, to be expended in erecting a stand pipe in the West End.

Whiteville, N. C.—Local press reports state that Oscar High will construct water works.

Marietta, O.—Supt. J. S. H. Torner writes that it is proposed to lay a new main from the pumping station on Ohio River to the new settling reservoirs, but bids have not yet been asked.

Platteville, Wis.—City Clk. Phil. D. Hendershot, Jr., writes that $15,000 water works extension bonds have been sold, and the city may engage Julius Fix, of Watertown, Wis., to prepare plans, etc.

Bellaire, O.—Supt. and Trus. of Water Works M. L. Blackburn, writes that at the election held recently, it was voted to issue $50,000 bonds to refund the 6 per cent. bonds and improve the pumping station.

Jacksonville, Ill.—City Clk. Sam. B. Stewart writes that this city has turned its water works over to W. T. Mayhon & Co., of Chicago, to operate for a term of 30 years.

Grand Rapids, Mich.—Local press reports state that for the purpose of purifying the Grand Rapids water supply and preventing contamination of Grand River above the intake at Coldbrook St., the city may extend sewers along the east and west sides of the river to the city limits, and ask the State to further extend the east side mains to the Soldiers' Home.

Lancaster, O.—City Engr. John N. Wolfe writes that bids are being received for $25,000 bonds for water works improvements. Geo. Cunningham, Clk. and Secy. of Water Wks. Trus.

Lansing, Ia.—A site is reported to have been selected for the pumping station of the water works system which, it is estimated, will cost $13,000.

Youngstown, O.—According to press reports the Council has decided to submit the question of issuing $250,000 filtration bonds to a vote of the people.

Milwaukee, Wis.—City Engr. Poetsch is planning to carry the city water mains under the river and under the depressed tracks of the 18th Ward through brick conduits 7 ft. in height. Seven conduits are planned to cross the river at different points, as soon as the deepening of the river makes it necessary to lower the water mains now in position.

Burlington, Ia.—The Citizen's Water Co., of Burlington, has been incorporated with a capital of $330,000, for the purpose of acquiring, operating, maintaining and extending the existing system of water works in Burlington. Incorporators: Jas. A. Guest; Seymour H. Jones; Edw. Hageman and others.

Detroit, Mich.—The Water Bd. has authorized the issue of $50,000 bonds to be sold in Jan. to pay for the new intake tunnel.

Clayton, Mo.—County Clk. Henry C. Helmering writes that the Missouri & Meramec Water Co., of which J. R. Waddell, 714 Wainwright Bldg., St. Louis, is Pres., proposes to construct a canal in St. Louis Co.

Lawrenceburg, Tenn.—The taxpayers will vote on the water works and electric light question.

Granger, Tex.—W. H. Kelso & Co. have sold the water works at this place. According to local press reports, Mr. Kelso, who will continue as manager, states that a stand-pipe will be constructed and the entire system improved.

Kansas City, Mo.—The contract for pumps for the Turkey Creek Pumping Station has not been let on bids received Sept. 1. The Council on Nov. 11 passed an ordinance authorizing the Bd. of Pub. Wks. to employ expert engineers, Geo. H. Benzenberg, John Donnelly and S. A. Mitchell, to prepare specifications, forms of proposals and advertisements for the new pumps needed at Turkey Creek and Quindaro. They are to make another examination of the conditions at these two plants and report on immediate needs and at the same time file a definite date when new machinery must be installed and in operation.

The Lower House of the Council has passed an ordinance appropriating $10,000 for the purchase of pipe to be used in extending water mains in the residence district.

Pascagoula, Miss.—It is proposed to establish municipal water works and an electric light plant.

Yazoo City, Miss.—The City Council has sold $175,000 bonds for the construction of water works, sewerage and an electric light plant.

Hannibal, Mo.—Capt. C. J. Lewis, Supt. of the Hannibal Water Co., has returned from St. Louis, where he received the authority of the management of the company to begin work on the improvements on the plant, which will mean an expenditure of $43,000.

Memphis, Tenn.—Local press reports state that the Artesian Water Co. will replace all its iron service pipes with lead pipes, on the streets to be paved with asphalt. Probable cost, $10,000.

Hidalgo, Tex.—The Hidalgo Canal Co., of Hidalgo, has been incorporated, with a capital stock of $500,000. Purpose, to construct a general system of irrigation, building a canal from the Rio Grande, also a water supply for the city waterworks. Incorporators: Wm. Briggs, H. W. Lanz, of Lake Charles, La.; F. B. Carroll, of Jennings, La., and others.

Beaumont, Tex.—A permit to do business in Tex. has been granted to the Glayds Electric Light, Water & Power Co. of South Dakota; capital stock, $100,000. The Texas office is to be located in Beaumont.

Gadsden, Ala.—F. A. Mitchell and associates have been granted a franchise to build and operate water works in Gadsden.

Meridian, Miss.—It is stated that plans and bids are wanted Dec. 4 for constructing water works. A. W. Washburn, Chmn. Council Water Com.

Cedar City, Utah.—Recorder R. W. Hegborne writes that at the election held Oct. 25 it was voted to issue $9,200 bonds for the construction of water works.

Meeteetse, Wyo.—City Clk. E. P. Bowman writes that on Nov. 11 it was voted to issue $10,000 bonds for constructing a system of water works.

Arcata, Cal.—The Reclamation Water Co., principal place of business, Arcata, has been incorporated with a capital of $12,080. Directors: E. B. Jackson, R. Q. Pull, M. P. Roberts and others.

Gunnison, Colo.—The proposition to grant a water works franchise is reported to have carried.

Washtucna, Wash.—The construction of a system of water works is said to be coatemplated.

Havre, Mont.—The Town Council is reported to have accepted the proposition of E. V. Hauser for water works and electric lights.

Sacramento, Cal.—It is stated that bids will be received Jan. 1 by the City Trus. for $150,000 bonds, to be used for extending the water mains.

Palisades, Colo.—Ch. of the Hydrographic Dept. of the Government, Mr. Newell, has recommended to the Secy. of the Interior the construction of a High Line canal to be taken out of the Grand River above Palisades.

Salt Lake City, Utah.—Articles of incorporation have been filed by the Big Cottonwood Lower Canal Co., its purpose being to operate a canal and irrigation system tributary to the Big Cottonwood Lower Canal. Capital, $24,000. E. H. Williams, Pres.; Jos. Sutherland, Secy. and Treas.

Phoenix, Ariz.—City Engr. Farrish estimates the cost of a complete system of water works for the city at $270,000.

Los Angeles, Cal.—The Los Berros Land & Water Co. has been incorporated, with a capital stock of $100,000. Directors: C. M. Stimson, S. H. Mott and W. E. Cummings, of Los Angeles, and others.

Oakland, Cal.—Milton French, H. H. Linnell, N. P. Williams and others have incorporated the Pure Water Co., with a capital of $30,000.

Aylmer, Ont.—Town Clk. J. Bradley writes that the city contemplates improving and extending its water works at a cost of $38,000. Bids will be received for two filters. H. E. Brownlee, Engr. in Charge.

Tampico, Mex.—Press reports state that Jas. P. McDonald, of Knoxville, Tenn., has received the contract for the construction of water works and a sewerage system for Tampico, aggregate cost to be about $2,000,000.

Cienfuegos, Cuba.—The Municipal Council of Cienfuegos has appointed H. J. Reilly, of New York, to draw up plans and specifications in view of the construction of a market, water works and sewer system at an estimated cost of $4,000,000.

SEWERAGE AND SEWAGE DISPOSAL.

Revere, Mass.—At a recent town meeting it was voted to petition Legislature for permission to borrow $100,000, outside the debt limit, to connect the sewers of the town with the metropolitan sewer at Chelsea.

New York, N. Y.—The following bids were opened Nov. 18 by Geo. Livingston, Comr. Pub. Wks., for the construction of a sewer in Stanton St., between Mangin and Ridge Sts.; A, F. Thileman, Jr.; B, N. Y. Sewer Constr. Co.; C, Wm. J. Moore; D, Wm. E. Welch; E, John A. Hadert; F, Norton & Dalton:

Items and Quantities.	A	B	C	D	E
4-ft. brick sewer—					
Class I, 1,100 ft......	$22	$19	$15	$13	$13.09
Class II, 500 ft.......	17	15	15	13	13.09
Class III, 238 ft......	17	14	14	13	13.09
12-in. vit. pipe, 100 ft...	5	3	3	3	4.00
Timber & plkg., 90,000 ft.	..	25	..	30	1.00
6-in. drains, 100 ft.....	1	3	3	1	1.00

Bids were opened at the same time for repairs to sewer in 12th and 13th Aves., 27th to 29th Sts., etc., as follows:

Items and Quantities.	A	B	C	D	E	F
4-ft. circular, 972 ft....	$18	$21	$15	$12	$14	$18.50
4′x2′ 8″ sewer, 240 ft...	14	17	10	12	10	17.25
3′ 6″x2′ 4″ sew., 1,012 ft.	14	*15	7	12	*6	15.75
12-in. vit. pipe, 84 ft...	3	2	3	3	4	3.00
Timber & plkg., 25,000 ft.	..	30	..	30	40	..

*Should read $15.85 and $6.50.

Syracuse, N. Y.—City Engr. Frank J. Schnauber estimates the cost of constructing a brick sewer, 46 x 69 in. and 40 x 60 in., in Midland Ave. at $28,000.

York, Pa.—The Common Council has passed on final reading an ordinance providing for an election to vote on the proposed increase of the city indebtedness to the extent of $400,000 for the construction of a sewerage system.

Oneida, N. Y.—The only bids received Nov. 11 for the construction of a trunk sewer were from De Nallo & Klingberg, of Kingston, N. Y., and Chas. H. Bartow & Co., being respectively as follows: 20-in. pipe, $6.50 and $10; 18-in. pipe, $5.30 and $6; 15-in. pipe, $3.45 and $5; manholes, $60 and $100; manhole junctions, $65 and $100; flush tanks, $50 and $100; 16-in. cast iron pipe at R. R. crossing, $13 and $20; brick masonry, $10 and $10; 12-in. pipe, $2.75 and $2; Portland cement concrete, $8 and $7.50; 8-in. pipe, $2.25 and $1; lumber, $22 and $40; 6-in. pipe, $1 and 75c.; totals, $39,484 (awarded) and $43,825.

Johnstown, N. Y.—The Sewer Com. has reported favorably upon the construction of a 30-in. vitrified pipe, about 800 ft. long with 8 intake basins. J. W. Miller, City Engr.

Colwyn, Pa.—John C. Wolfenden, Clk. of Council, writes that on Nov. 4 it was voted to issue $7,000 bonds for extending the sewerage system and improving the public highways.

Tonawanda, N. Y.—The Municipal Bd. is said to be considering the question of establishing a sewage disposal plant.

Westfield, Mass.—Town Engr. Oren E. Parks writes that the following bids were opened Nov. 5 for building Section 2 of the storm water sewer system.

Items and Quantities.	R. D. Maynard, Springfield.	Bruno, Salomone & Petittie, Boston.	D. W. Mellen, Springfield.	Frank. L. Allen, Worcester.	Rowe & Perini, So. Framingham.	D. J. Curtis, Springfield.	Geo. M. Atkins & Co., Palmer.	Michael Maloney, Springfield.
Earth exc., 54-in. sew., 2,075 ft.	$1.53	$1.98	$2.20	$2.50	$2.43	$2.67	$3.00	$2.87
Earth exc., 48-in. sew., 2,980 ft.	1.30	1.85	2.00	1.80	2.15	2.70	2.80	3.00
Earth excav., 42-in. sew., 560 ft.	1.00	1.75	1.75	1.50	1.79	2.60	1.90	2.58
Earth excav., 36-in. sew., 335 ft.	.85	1.75	1.60	1.25	1.50	1.87	1.80	2.15
Earth excav., 30-in. sew., 60 ft..	1.10	1.75	1.60	1.50	1.84	1.80	1.80	1.90
Brick masonry, 2155. cu. yds...	12.00	11.75	12.10	12.50	12.40	12.00	12.00	12.50
Concrete masonry, 400 cu. yds..	6.00	6.15	7.00	7.00	6.95	7.00	7.00	7.00
Piles in place, 375 ft..........	.25	.50	.35	.50	.50	2.00	1.00	.85
Spruce lumber, 10 M ft., B. M..	25.00	35.00	30.00	40.00	35.00	30.00	40.00	22.00
Totals	$36,563	$39,611	$41,443	$42,225	$43,104	$45,486	$45,779	$47,450

Note.—Mortar for brickwork, Portland Cement 1:2½. Concrete masonry, Portland Cement 1:3:6. Earth excavation, average cut—54-in., 13.1 ft.; 48-in., 12.1 ft.; 42-in., 10.7 ft.; 36-in., 8.9 ft.; 30-in., 12.0 ft.

Buffalo, N. Y.—Bids are wanted Nov. 27 for constructing a 10-in. tile sewer in Chelsea Place, a 10, 12, 15, 18 and 20-in. tile sewer in Freund St., also a 12-in. tile sewer in Manhattan Ave. and Weimar St. Bids are also wanted Nov. 28 for constructing a 10-in. tile sewer in Mathews St. and a 24-in. brick, 18 and 20-in. tile sewer in New South Ogden St. Francis G. Ward, Comr. Dept. of Pub. Wks.

Saratoga Springs, N. Y.—See "Water."

Roselle Park, N. J.—Boro. Clk. A. M. Woodruff writes that the following bids were opened Nov. 8 for the construction of a sewerage system, work to include 45,970 ft. of 8 to 15-in. pipe sewers, 140 manholes and 27 flush tanks; David Harper, Newark, N. J., $55,946; Union Building & Const. Co., Passaic, N. J., $51,542; Wm. J. McCloud & Co., Elizabeth, N. J., $58,362; J. Roosevelt Shanley, Jersey City, N. J., $51,640; Higginson & Shannon, Jersey City, N. J., $44,441.

Washington, D. C.—The following bids were opened Nov. 15 by the Commissioners, D. C., for constructing a portion of the low area trunk sewer in the Dist. of Columbia: The Warren F. Brenizer Co., 15th and G Sts., Washington, $73,665 (accepted); Andrew Gleeson, Washington, $104,820; E. G. Gummell, Eckington, D. C., $92,650; Patterson & Brierson, Baltimore, Md., $80,645.

Brooklyn, N. Y.—The following bids were opened Nov. 19 by Wm. C. Redfield, Comr. Pub. Wks., for alteration of sewers necessitated by Atlantic Ave. Improvement Subway, in Franklin Ave., from Atlantic Ave. to Brevoort Pl., etc., only the main items being given:

Items and Quantities.	John J. Cashlan.	John O'Grady.	James H. Holmes & Co.
54-in. brick sewer, 2,035 ft.......	$13	$17	$11
Manholes, 17.....................	35	75	39
Founda. planking, 18,000 ft......	20	20	25
Sheeting, etc., 285,000 ft.........	20	20	23
Siphon "A," complete............	3,400	2,100	1,300
Siphon "B," complete............	4,900	3,350	3,100

North Plainfield, N. J.—The estimated cost of installing a complete sewerage plant is placed at $48,000, and the cost of a disposal plant at $38,000.

Saratoga Springs, N. Y.—Bids will be received Nov. 26 by the Village Sewer, Water and Street Comn. for furnishing materials and constructing a 10-in. terra cotta sewer in portions of Greenfield Ave. H. F. Thomas, Clk.

St. Petersburg, Fla.—Bids will be received Dec. 10 by the City Council for constructing a sewerage system. The work includes the construction of approximately 13,000 ft. of 6 to 15-in. pipe, 25 manholes and 5 flush tanks. Address Grant J. Aiken, Clk.; J. P. Titcomb, City Engr.

Atlanta, Ga.—See "Water."

Cincinnati, O.—Bids are wanted Dec. 12 for improving portions of several streets by constructing sewers and drains with the necessary appurtenances thereto. Robt. Allison, Pres. Bd. of Pub. Service.

City Engr. Stanley has been directed to prepare plans and specifications for a sewer in 8th and several other streets, Price Hill. Probable cost, $20,000.

Milwaukee, Wis.—The City Council has allowed $16,000 for the construction of a brick tunnel to drain the west part of 19th Ward.

Monmouth, Ill.—The Bd. of Local Improvement has decided to recommend to the City Council the construction of the Central sewer, which is to be of brick, 36-in. in diameter, and will cost about $7,000.

Madison, Wis.—City Engr. John F. Icke writes that all bids received Nov. 14 for the construction of 2 miles of sanitary sewers, have been rejected as too high; new bids will be asked in the spring.

Washington, Ia.—City Clk. Hugh H. McCleery writes that the construction of a sewage disposal plant at a cost of $3,000 or more is contemplated; additional sewers will be put in.

Connersville, Ind.—City Clk. Jacob S. Clouds writes that Chas. C. Brown, of Indianapolis, is preparing plans, estimates, etc., for proposed pipe sewers.

Indianapolis, Ind.—Bids are wanted Nov. 27 for constructing sewers in Arsenal Ave. Harold C. Megrew, Clk. of Bd.

Walnut, Ill.—Bids will be received Dec. 5 by the Drainage Comrs. of Dist. No. 1 of Hamilton and Hahnaman Townships for enlarging the main ditch of the Dist. Estimated, 634,380 cu. yds. excavation. Jas. Foley, Chmn.; P. C. Knight, Engr., Pontiac, Ill.

Massillon, O.—Bids will be received Dec. 2 by the Sewer Comn. for constructing sanitary sewers in 2 streets. Orlando C. Volkmor, Clk.

Chicago, Ill.—Bids will be received Nov. 25 by the Bd. of Local Improv. for constructing vitrified tile pipe sewers, with manholes and catch-basins, in a number of streets; also brick and vitrified tile pipe sewers, with manholes and catch-basins, in several other streets. Andrew M. Lynch, Pres.

Waukegan, Ill.—Bids are wanted Nov. 28 for constructing about 1,680 lin. ft. of 24-in. vitrified tile sewers. F. Finer, Pres.

Joplin, Mo.—The citizens of South Joplin are considering the question of sewerage.

Johnson City, Tenn.—Consulting Engr. Samuel M. Gray, of Providence, R. I., writes that this city proposes to construct a sewerage system; estimates for same have not yet been made, and contracts for construction will probably not be let for several months. E. E. Ellisworth, Chmn. of Sewer Com.

Osceola, Ark.—Bids are wanted Nov. 28 at the County Clerk's Office for the construction of 27½ miles of drainage canal, as advertised in The Engineering Record.

Athens, Tenn.—The Chamber of Commerce has appointed a Com. to investigate the cost of building sewers in Athens.

Topeka, Kan.—Local press reports state that it is proposed to build a 36-in. sewer, either pipe or brick, on Euclid Ave. Address City Engr. McCabe.

Beaumont, Tex.—Bonds to the amount of $75,000 were voted at the recent election for sewers.

Yazoo City, Miss.—See "Water."

New Orleans, La.—The Sewerage & Water Bd. has adopted a resolution accepting the bid of the Camden Iron Wks. for furnishing pumping, steam and electrical equipment, as per contract D, for the sum of $246,500, being the lowest bid submitted Aug. 12.

Athens, Ala.—The Chamber of Commerce has taken steps to ascertain the cost of constructing a sewerage system.

Oklahoma, Okla. Ter.—The City Council has decided to extend the 1st St. storm sewer a distance of 3,100 ft. Cost about $15,000.

Fresno, Cal.—City Engr. I. Teilman writes that in Dec. a special election will be held to vote on the issue of $55,000 bonds for septic tank and intercepting sewer.

Long Beach, Cal.—At a recent citizens' meeting a vote was taken in favor of the issue of $30,000 bonds for the construction of a sewerage system.

San Diego, Cal.—The Sewer Com. has recommended that provision be made in the proposed bond issue for sewers to cost $137,457.

Seattle, Wash.—The Council has passed a resolution providing adequate sewerage for Madison St. Dist.

New Hope, Cal.—It is stated that plans have been prepared for the joint construction of a steel bridge over the Mokelumne River west of New Hope by San Joaquin (Stockton, C. H.) and Sacramento (Sacramento, C. H.) Counties; estimated cost, $20,000.

Manitou, Colo.—The Town Bd. has authorized preliminary surveys for extension in the sewer system estimated to cost about $20,000.

Tampico, Mex.—See "Water."

Toronto, Ont.—The Bd. of Control has decided to confer with the Medical Health Officer and City Engr. to see if they cannot be got to agree upon some system of sewage disposal.

Montreal, Que.—Local press reports state that the contract for extending St. James St. sewer has been awarded to Mony & Co., at $33.74 a yd.; $8,000 to be spent on the work this fall.

Cienfuegos, Cuba.—See "Water."

BRIDGES.

Boston, Mass.—City Engr. Wm. Jackson estimates the cost of constructing a bridge at Wordsworth St., East Boston, at $4,500.

Springfield, Mass.—Mayor Ellis has announced to the Board of Aldermen the appointment of Judge E. F. Lyford, Nathan D. Bill and Alderman Everett E. Stone as members of the Special Comn. to investigate the question of a proposed new bridge over the Connecticut River, the commission having been provided for in an order passed by City Council on Jan. 28.

Windsor Locks, Conn.—See "Railroads."

Woonsocket, R. I.—City Engr. Mills estimates the cost of building a new arch bridge over Blackstone River on S. Main St., at $36,300, and an ordinance appropriating this amount has been introduced in the Bd. of Aldermen.

Haverhill, Mass.—See "Electric Railways."

Allegheny, Pa.—It is stated that a new bridge has been planned across Ohio River between McKees Rocks and Woods Run, Allegheny. It will be built by the Western Bridge Co., a corporation formed by Pittsburg and Allegheny capitalists, and including in its membership officials of the Pittsburg Rys. Co.

It is stated that the Pennsylvania R. R. Co. has in contemplation the construction of a bridge from Herrs Island, the site of the new stock yards, over the back-channel of the Allegheny River to Allegheny, to connect the tracks on the island with the West Penn division. W. H. Brown, Ch. Engr., Philadelphia.

Scranton, Pa.—The Scranton Ry. Co. (E. D. Reed, Ch. Engr., Scranton) and the Delaware, Lackawanna & Western R. R. Co. (W. K. McFarlin, Ch. Engr., Hoboken, N. J.) are stated to have approved plans for the West Lackawanna Ave. viaduct, to cost about $80,000.

McKees Rocks, Pa.—The Engineering Dept. of the Pittsburg & Lake Erie R. R. is stated to have completed plans for a bridge across the McKees Rocks yards, to be known as the Island Ave. span; it will cost about $15,000. J. A. Atwood, Ch. Engr., Pittsburg.

Duryea, Pa.—The Grand Jury is stated to have recommended that $5,000 be appropriated to construct a bridge across Lackawanna River at Duryea. (Wilkesbarre, C. H.)

McKeesport, Pa.—The Dirs. of the Port Vue Bridge Co. at a meeting here Nov. 13 decided to make additional improvements to the bridge at a cost of about $5,000. Wm. P. Wampler, Pres.

Washington, Pa.—Bids are wanted Nov. 25 for constructing stone abutments for bridge in Deemston Boro.; also for bridge in East Finley Township over Rockey's branch of Wheeling Creek. W. G. Shillito, Chmn. of Co. Comrs., Cumberland, Md. Bids will be received Nov. 25 by the Com. on Streets and Alleys for constructing 3 steel beam and concrete bridges in this city. D. P. Le Fevre, City Engr.

Jamaica, L. I., N. Y.—The contract for building 3 steel bridges over the Long Island R. R. tracks at Washington, Prospect and Union Hall Sts. is stated to have been awarded to the Owego Bridge Co., Owego, N. Y., work to be competed May 1. The bridges will be 107 ft. long and 60 ft. wide, allowing for a 40 ft. roadway with two 10 ft. sidewalks. The entire work of the improvement, including excavation and laying of the 6 tracks from Jamaica station, through the village to Rockaway Junction, and the building of the bridges, will cost $100,000.

Berkley, Va.—The Superv. of Norfolk County and the Norfolk, Portsmouth & Newport News Consolidated Ry. Co. are reported to have under advisement plans to build a bridge across Piscara Creek at the terminus of the company's present line near the Union stock yards; probable cost, $5,000.

Tallahassee, Fla.—The Counties of Leon and Gadsden are stated to have agreed to build a bridge across the Ocklockonee River near Jacksons Bluff; a committee has been authorized to employ a civil engineer to prepare plans for the War Dept.

Des Moines, Ia.—Local press reports state that an effort is being made to secure an order for a viaduct over the Keokuk & Western R. R. tracks on what is known as the Bloomfield Road on the South Side. The viaduct and approaches would cost about $18,000.

Dayton, O.—City Engr. Frank M. Turner is reported to be preparing plans for 2 bridges over the Miami, one at 3d St. and the other at Stratford Ave. The one at 3d St. will be constructed first.

Rockford, Ill.—The Bd. of Superv. is said to be considering the construction of a 3-span bridge at South Beloit across Turtle Creek.

Peoria, Ill.—A resolution has been introduced in Council providing for the replacing of the low free bridge with a new structure.

Muscatine, Ia.—As no bids were received for the construction of the 4th St. foot-bridge across Mad Creek, the City Council is reported to have decided to do the work itself, and Alderman Duffield has been appointed to superintend its construction. The plans call for a 2 span 80 ft. bridge.

Washington, Ind.—The contract for erecting a bridge over the west fork of White River, joining Daviess and Knox Counties, is stated to have been awarded to the Indiana Bridge Co., Muncie, for $13,664.

Minneapolis, Minn.—Bids are wanted Dec. 1 for rebuilding bridge No. 120 over Bassett's creek in Golden Valley, bridge No. 126 on River Road in Brooklyn, and bridge No. 184 between Dayton and Hassan. Hugh R. Scott, Co. Aud.

Milwaukee, Wis.—The Council on Nov. 17 passed a resolution providing for the issue of $100,000 bonds for the Washington Ave. viaduct.

Unionville, Wis.—Bids will be received Dec. 2 by G. W. Dickson, Bridge Comr., for constructing a steel bridge across Shoal Creek, Lincoln Township.

Houston, Wis.—City Clk. R. S. Joslin writes that on Nov. 4 it was voted to construct a bridge across Lemouweir River, at a cost of $5,000.

Osceola, Mo.—Bids will be received Dec. 3 by W. A. Ingram, Co. Road and Bridge Comr., for constructing stone piers at the bridge to be erected over Big Monegan on the Taberville and Monegan road.

Chattanooga, Tenn.—Local press reports state that the Queen and Crescent Route will build a new and heavier bridge across Tennessee River, to replace the present bridge about 5 miles above this city. Geo. B. Nicholson, Ch Engr., Cincinnati, O.

Asher, Okla. Ter.—It is reported that preliminary soundings have been made for a steel toll bridge across the Canadian River at Asher, which a stock company proposes to construct.

Astoria, Ore.—A petition, asking that a special levy of 1½ mills be made for a period of 4 years for the purpose of constructing a drawbridge across Lewis and Clark River near its mouth, was presented to the County Comrs. The special levy will raise in the 4 years between $18,000 and $20,000.

Sheldon, Cal.—County Surveyor Boyd has submitted to the Bd. of Superv., Sacramento, plans and specifications for a bridge to cross Cosumnes River at Sheldon.

Sioux Falls, S. D.—The Co. Comrs. are stated to have ordered a 70-ft. steel bridge erected over the north end of Covell's Lake.

Victoria, B. C.—The following bids were opened Oct. 27 for constructing the steel superstructure of a bridge at Point Ellice; C. H. Topp, City Engr.: King Bridge Co., Cleveland, O., 6 55/100 cts. per pound weight; Canadian Bridge Co., Walkerville, Ont., 6 97/100 cts. per pound weight; Heenan & Froude, Manchester, Eng., 7 cts. per pound weight; Dominion Bridge Co., Montreal, P. Q., 6 54/100 cts. per pound weight; Victoria Machinery Depot Co., Ltd., Victoria (awarded), 6¼ cts. per pound weight; Puget Sound Bridge & Dredging Co., Seattle, Wash., for bridge and floor complete with concrete piers and abutments, $99,000.

PAVING AND ROADMAKING.

Woonsocket, R. I.—An ordinance has been introduced in the Common Council providing for an appropriation of $44,000 for highway purposes.

Haverhill, Mass.—See "Electric Railways."

Hartford, Conn.—Bids are wanted Nov. 26 for furnishing and laying the concrete base and sheet asphalt wearing surface of about 5,605 sq. yds. on Pearl St., as advertised in The Engineering Record.

Boston, Mass.—The following bids were opened Nov. 17 for constructing two sections of Columbia Road, one between I and Q Sts., S. Boston, the other between Buttonwood St. and the N. Y., N. H. & H. R. R. bridge, Dorchester, the roadway to be macadam on a telford base. For South Boston section—W. H. Ellis, $51,061; P. McGovern, $38,055; McGawley & Coughlan, $41,322.40; H. P. Nawn, $37,821; J. J. Sullivan, $74,021. Contract awarded to H. P. Nawn, of Boston, whose bid on items was: Removing trees, $50; earth excavation and sub-grading, 24 cts. per cu. yd.; gravel, $1 per cu. yd.; edgestones, 17 cts. per lin. ft.; telford base, 33 cts. per sq. yd.; 4-in. macadam, 17 cts. per sq. yd.; 9-in. macadam, 24 cts. per sq. yd.; flagging, $2.25 per sq. yd.; brick paving, 35 cts. per sq. yd.; gutter paving, 55 cts. per sq. yd.; 5-in. crushed stone sidewalk, 17 cts. per sq. yd.; 4-in. crushed stone sidewalk, 16 cts. per sq. yd.; loam, $1.15 per cu. yd.

For the Dorchester section—W. H. Ellis, $10,323; J. J. Sullivan, $18,267; Edw. J. Hayden, $25,962; McGawley & Coughlan, $12,288; H. P. Nawn, $10,496; W. J. Berry, $10,430; P. Doherty, $9,748 (contract awarded).

Bids will be received Nov. 26 by Jas. Donovan, Supt. of Streets, for constructing a macadam road on portions of Lindsey St.

Buffalo, N. Y.—Bids were opened Nov. 14 by the Bd. of Pub. Wks. for paving and repaving portions of several streets, the lowest bids being as follows: A, H. P. Burgard, Buffalo; B, Barber Asphalt Paving Co., Buffalo; S. Division St., 2,677 sq. yds., A, $8,000 for stone, and $5,948 for brick; B, $4,149 for asphalt. S. Division St. (another section), 2,704 sq. yds., A, $4,000 for asphalt, and $8,700 for stone; B, $6,706 for brick. 17th St., 1,283 sq. yds., A, $1,900 for asphalt, and $4,000 for stone; B, $3,284 for brick. Niagara St., 7,268 sq. yds., A, $11,000 for asphalt, and $23,500 for stone; B, $17,807 for brick. Willow Place, 873 sq. yds., A, $3,000 for stone, and $2,500 for brick; B, $2,244 for asphalt.

The Bd. of Aldermen has directed Col. Francis G. Ward, Comr. of Pub. Wks., to prepare plans, at a cost not to exceed $1,000, for the proposed elevated roadway along Hamburg turnpike to the city line.

York, Pa.—The Common Council has passed the ordinance providing for the paving with macadam of Biddle St.

Milton, Pa.—At an election to be held Feb. 17 a vote will be taken on the proposition to issue $12,000 bonds for the purchase of a stone crusher and steam roller.

Albany, N. Y.—It is estimated by the State Engr.'s Dept. that by the time the next Legislature is ready to make an appropriation for good roads, the County Boards of Supervisors shall have adopted plans for roads calling for an aggregate expenditure of $4,000,000. The State's share of this expense would be $2,000,000.

Newark, N. J.—The Bd. of Health in a communication to the Bd. of Pub. Wks. has recommended that Campbell St. be paved with either granite block or asphalt.

Binghamton, N. Y.—Broome Co. Bd. of Supervisors adopted final resolutions for several good roads appropriating $37,775 therefor.

Brooklyn, N. Y.—Ch. Engr. Tillson in a recent report to the Boro. Pres. on the proposition to widen Livingston St. from Flatbush Ave. to Court St. places the estimated cost at $1,800,000. Mr. Tillson recommends that 60 ft. be added to the present width of the street.

New York, N. Y.—The following bids were opened Nov. 18 by Geo. Livingston, Comr. Pub. Wks., Manhattan, for repaving with asphalt on present pavt. relaid as foundation 116th St., from Ave. A to Morningside Ave.: A, Asphalt Constr. Co.; B, Barber Asph., Pavg. Co.; C, Century Constr. Co.; D, Continental Asph. Pavg. Co.; E, Sicilian Asph. Pavg. Co.:

Bidders.	Asph., 31,400 sq. yds.	Old pavt. relaid, 8,550 sq. yds.	Concrete, 2,825 cu. yds.	New curb, 5,670 ft.	Old curb reset, 8,504 ft.	Manhole covers, 20.
A............	$1.25	$0.30	$5.50	$0.85	$0.25	$6
B............	1.17	.40	4.80	.80	.37	20
C............	1.39	.30	5.00	.82	.33	20
D............	1.25	.32	5.50	.70	.30	20
E............	1.10	.20	4.90	.80	.30	17

Silver Lake, N. Y.—A. J. Strange, Asst. Engr., Richmond County Park Comrs., New Brighton, N. Y., writes that the following bids were opened Nov. 17 by said Comrs. for furnishing labor and material for constructing road in Silver Lake Park, containing approximately 8,285 yds. of 12-in. telford and macadam and 3,115 sq. yds. of 6-in. macadam: Jos. Johnson, West New Brighton, S. I., N. Y., $16,372; E. K. Whitford, Port Richmond, N. Y., $16,798; A. R. Gold, Tompkinsville, S. I., N. Y., $14,500 (awarded).

Syracuse, N. Y.—The following bids were opened Nov. 17 for paving portions of Warren and Willow Sts.: F. J. Saker, Syracuse, (brick), $7,160; Empire Contracting Co., Syracuse (asphalt), $6,209.

Colwyn, Pa.—See "Sewerage and Sewage Disposal."

Pittsburg, Pa.—The Council on Nov. 17 passed a resolution appropriating $40,000 for repaving N. Negley Ave. and $9,500 for Stanton Ave.

New York, N. Y.—Bids will received Dec. 2 by Jacob A. Cantor, Boro. Pres., for regulating, grading and repaving the roadway of 7th Ave. from 110th St. to 120th St. Engineer's estimate calls for 23,650 sq. yds. of bituminous macadam pavement, 800 lin. ft. new curbstone, and 4,300 lin. ft. old curbatoue.

Baltimore, Md.—Bids are wanted Dec. 3 to grade, curb and recurb where necessary and pave with vitrified brick portions of Northwest St. B. T. Fendall, City Engr.; Thos. G. Hayes, Pres. Bd. of Awards.

Gloversville, N. Y.—City Engr. Morrell Vrooman writes that about 17,000 sq. yds. of macadam and about 8,000 sq. yds. of vitrified brick pavement will be done by contract during the coming year.

Savannah, Ga.—The City Council has adopted the ordinance providing for a vitrified brick pavement on 36th St.

Charlottesville, Va.—R. W. Duke, Clk. of the Corporation Court, writes that the proposition to issue $80,000 bonds for street improvements was defeated at the election held Nov. 4, but that another election will be held Dec. 17 to vote on this proposition.

Evanston, Ill.—A petition has been presented to the Bd. of Local Improvements for paving Dempster St., between Ridge and Dodge Aves., with granite-top macadam; work will probably be ready for letting by May 1, 1903. John H. Moore, City Engr.

Weston, O.—Town Clk. F. A. Henderson writes that on Nov. 4 it was voted to macadamize the roads of Weston Township.

Iowa City, Ia.—Engr. Magowan estimates the cost of paving Linn St. as follows: 11,690 sq. yds. of brick paving at $1.60 per sq. yd., 4,413 ft. of curbing at 50 cts. per ft., with storm-water inlets, etc.; total, $23,331.

Kalamazoo, Mich.—Comrs. of Pub. Improv. John J. Knight and O. K. Buckhout, with Engr. Geo. S. Pierson, have been inspecting various kinds of paving with a view to letting contracts for paving in this city in the near future.

Cincinnati, O.—City Engr. Stanley estimates the cost of paving with brick on Dorsey St. at $13,586.

A petition has been filed with the Bd. of Pub. Service asking that a portion of 5th St. be paved with asphalt.

Toledo, O.—According to local press reports the lowest bids received for paving Front St. were as follows: Bodette & McMahon, brick on sand, Athens block, at $23,176; also brick on concrete, Athens block, at $33,568. C. H. Burchinal, for asphalt block on concrete at $52,453, and for asphalt block on sand, $45,429; Harry Jennison, for Medina block on sand, at $52,429.

Grand Rapids, Mich.—The City Engr. estimates the cost of asphalt block paving on a concrete foundation, with 5-year guarantee for Wealthy Ave., at $65,243; cost with 10-year guarantee, $73,296; for sheet asphalt with 2-ft. concrete gutter and 10-year guarantee for said street, the estimated cost is $55,303, and for brick block paving on concrete the cost is estimated at $48,511.

Red Oak, Ia.—The City Council has approved 4 ordinances for paving.

St. Paul, Minn.—Property owners will ask the city to bear a portion of the expenses of paving W. 7th St. from Ft. Snelling to St. Paul. Total cost to be about $76,000.

Milwaukee, Wis.—The Common Council on Nov. 17 passed the ordinance appropriating $225,000 for permanent street improvements.

Marion, Ia.—Street improvement bonds to the amount of $10,000 are reported to have been authorized.

Green Bay, Wis.—Bids are wanted Dec. 11 for improving streets. W. L. Kerr, City Clk.

St. Joseph, Mo.—A plan is said to be under consideration for the paving with asphalt of all the unpaved streets of the city.

Nashville, Tenn.—According to local press reports this city has purchased from the Warren Bros. Co., for $8,000, the bituminous macadam plant erected in Nashville to fill contracts with the city.

Louisville, Ky.—The Bd. of Pub. Wks. is reported to have awarded to Lee Figg and Geo. W. Gosnell, the lowest bidders, contracts for vitrified brick paving in portions of Castlewood Ave., Greenwood and other streets, in all amounting to about $40,000; the average price per sq. yd. being $1.37.

Beaumont, Tex.—At the recent election it was voted to issue $95,000 paving bonds, in addition to the $125,000 now being expended by the City Council in street improvements.

Dallas, Tex.—Plans are said to have been prepared for the repaving of Main St. from Ervay St. to Exposition Ave. with asphalt.

Oakland, Cal.—The City Engr. has submitted plans for the improvement of San Pablo Ave. from 14th to 36th Sts., and the estimated cost is placed at $106,000; plans have also been submitted for the making and fitting up of the park between 8th and 12th Sts., and the improvement of 8th St. south of the park, at an estimated cost of $145,000.

POWER PLANTS, GAS AND ELECTRICITY.

Holyoke, Mass.—The Bd. of Aldermen on Nov. 18 passed an ordinance authorizing the issue of $720,000 bonds to cover the purchase of the municipal lighting plants.

Buffalo, N. Y.—The Council is reported to be in favor of constructing a municipal gas plant.

Binghamton, N. Y.—The Chmn. of the Bd. of Superv. is about to appoint a committee to consider the question of installing a heating and lighting plant for the County Buildings, at a cost of $20,000.

Phoenixville, Pa.—It is stated that the Schuylkill Valley Illuminating Co. will begin at once the erection of a power plant at Cromby, one mile north of Phoenixville. J. W. Gillette is the Engr. who will superintend the building of the plant. W. D. Jones, Supt., Phoenixville.

Easton, Pa.—The City Council is stated to have granted franchises to the People's Steam Heat & Power Co. and to the Phillipsburg & Easton Conduit Co.

Mifflinburg, Pa.—Town Clk. F. M. Getgen writes that on Nov. 4 it was voted to issue $6,000 bonds for the construction of an electric-light plant for the Boro.

Kenmore, N. Y.—This village is about to install a gas distribution system and has awarded the contract for furnishing pipe, valves and fittings to the Darling Pump & Mfg. Co., Ltd., of Williamsport, Pa. Kenmore is to get its supply of gas from the Niagara Light, Heat & Power Co., of Tonawanda, N. Y., with whom it has a contract for 5 years. John B. Winter, of Buffalo, was the lowest bidder for laying the pipe, but the Bd. of Trns. has not yet awarded this contract.

Oneida, N. Y.—The Bd. of Pub. Wks. is stated to have received on Nov. 11 only 1 bid for lighting the streets for the next 2 years, and this was from the Madison County Gas & Electric Co. On the first proposition, that of furnishing 100 1,200-c. p. lamps, 30 to burn all night every night, the company bid $6,500. On the second, with the same number of 2,000-c. p. enclosed arc lamps, $7,160, and on the third, providing for all all-night lamps, $7,350.

Penngrove, N. J.—See "Water."

Yardville, N. J.—Chas. A. Camp and C. A. Budd, of Yardville, and Augustus Wolf, of Chambersburg, Pa., are stated to have secured a charter from the Sec. of State for the Yardville Electric Heat, Light & Power Co., with a capital of $25,000.

Altoona, Pa.—W. H. Herr is stated to have secured the contract for constructing the power plant at 9th Ave. and 20th St., for the Citizen's Electric Light, Heat & Power Co., for $11,490.

Baltimore, Md.—The contract for naphtha lighting is stated to have been awarded to the American Lighting Co. for 3 years at $23.45 per lamp per year.

A press report states that the purchase of the $2,000,000 of common stock of the United Electric Light & Power Co. from the United Rys. & Electric Co. by a syndicate acting through the Continental Trust Co., was concluded Nov. 15. The purchase of the control of the light and power compnay practically assures the Susquehanna River electric power development by the syndicate. There are to be 3 developments that will cost between $10,000,000 and $12,000,000, and 2 years will be required to complete the work, the purpose being to supply motive power for the street railway system of Baltimore, to supply electricity for lighting the streets and for general power and heating purposes.

York, Pa.—The Boro. Council of North York is stated to have granted the Merchants' Electric Light Co. permission to extend its pole line to North York. C. H. Bear, Pres.

Philadelphia, Pa.—Bids are wanted Dec. 20 for furnishing engines, generators, boilers, etc., for a complete electrical power plant for the Frankford Arsenal. Maj. Frank Heath Commanding.

Brooklyn, N. Y.—Bids were opened Nov. 20 for the completion of the central power plant for the Brooklyn Inst. of Arts and Sciences, as follows: Thos. Dwyer, $94,700; Thos. Cockerill & Son, $89,500; P. J. Carlin & Co., 26 Court St., $78,693.

Macon, Ga.—The Macon Ry. & Light Co. is stated to have secured the contract for lighting the city at $75 per light per year for 150 arc lights, 450 volts, 2,000 c. p.; all over that number, $72.50 each. Incandescent lights 15 cts. per Kw. hour, and for power 13½ cts. per Kw. hour.

Miami, Fla.—John B. Reilly is reported interested in the construction of an electric-light plant.

Barlow, Fla.—The citizens are stated to have voted to issue $15,000 bonds for an electric-light plant.

Cheraw, S. C.—The Council is reported to be considering the question of electric lighting.

Detroit, Mich.—The Lighting Comn. is stated to have awarded to the Bradley Mfg. Co., of Pittsburg, Pa., the contract for the engine for the power plant, at $14,600. The Stanley Electrical Co., of Pittsfield, Mass., secured the contract for the generator and exciting dynamo at $900, and the Westinghouse Electric & Mfg. Co., Pittsburg, Pa., the contract for the switchboard, instruments, and switches at $2,150.

Woodmere, Mich.—The Welsbach St. Lighting Co. is stated to have petitioned the Council for a franchise to light the streets of the village for a term of years.

Waterloo, Ia.—It is reported that the Council will secure estimates of cost of constructing an electric-light and gas system.

Canton, O.—The Metropolitan Paving Brick Co., W. E. Keplinger, Pres., writes: "We are in the market for an electric apparatus to operate about ¾ of a mile of tram-road, and also intend to light two of our plants by electricity."

St. Paul, Minn.—Bids will be received Dec. 2 by Matt Jensen, City Clerk, for lighting certain streets of the city with electricity, gas and gasoline.

St. Charles, Mich.—Village Clk. Jos. E. Brownell writes that bids will be opened Dec. 1 to construct an electric light plant estimated to cost $1,500. E. V. Parsons, Engr. in Charge.

Mankato, Minn.—City Engr. J. R. Thompson writes that on Nov. 7 the Council received the following bids for street lighting, for 1, 3 and 5 years respectively—*a*, every and all-night schedule; *b*, Philadelphia schedule: Mankato Gas & Electric Light Co., 65 or more 2,000 c. p. arcs, *a*, $105, $92 and $88, for 1, 3 and 5 years respectively; *b*, $84, $72 and $68; 100 or more 32 c. p. incandescents, *a*, $30, $28 and $29; *b*, $22, $20.50 and $20. American Development Co., 50 or more 1,000 c. p. lamps, *a*, $72, $71 and $70 for 1, 3 and 5 years respectively; *b*, $62, $61 and $60; 100 or more 60 c. p. lamps, *a*, $31, $30 and $29; *b*, $27, $26 and $25. The contract was awarded on Nov. 14 to the American Development Co., of St. Paul, for 1 year from Dec. 1, 1902. The Council will probably use about 25 of the 1,000 c. p. lamps at first and more of the 60 c. p.

Muscatine, Ia.—It is reported that Harry E. O'Neill, of Ottumwa, is about to submit a proposition to Council for the establishment of an electric light plant.

Waterloo, Ia.—The City Council is reported to have authorized the Committee on Light to investigate the cost of constructing a gas and electric plant to be owned and operated by the city.

Quincy, Ill.—Bids are wanted Nov. 26 for furnishing 336 electric arc lights, and lighting the streets of said city for a period of 3 years. Gottlieb Schanz, Chmn. Light Com.

Toledo, O.—The East Toledo Htg. & Light Co. is reported organized by L. E. Flory, F. E. McCory and others, to furnish heat and light in East Toledo.

Kewanee, Ill.—The Lighting & Htg. Co. of Kewanee has been incorporated with a capital of $50,000 to operate light, heat and power plants. Incorporators: X. Caverno, B. C. Parkinson and Jas. Nakes.

Pascagoula, Miss.—See "Water."

Linneus, Mo.—The citizens are stated to have voted on Nov. 10 to issue bonds for an electric-light plant and a public park.

Yazoo City, Miss.—See "Water."

Farmington, Mo.—The Laufketter-Bendit M. E. Co. of St. Louis, Mo., has been retained as consulting engrs. for the Farmington Electric Light & Ice Co., of Farmington, to remodel its electric-light and ice equipment. This Co. has been thoroughly reorganized, and will shortly be in the market for engines, generators, boilers, etc.

Nashville, Tenn.—See "Electric Railways."

Lawrenceburg, Tenn.—See "Water."

Tacoma, Wash.—R. G. Hudson and D. A. Worden are reported interested in the construction of a steam-heating and power plant, to cost about $50,000.

Havre, Mont.—See "Water."

Richmond, Cal.—The Richmond Light & Power Co. is reported incorporated, with a capital of $150,000, by W. A. Bissell, Walter P. Treat, and others, to furnish light and power in Richmond and other towns in Contra Costa County.

Ritzville, Wash.—See "Electric Railways."

Ord, Neb.—Jas. Barta is stated to have secured a franchise for an electric light plant.

ELECTRIC RAILWAYS.

Greenfield, Mass.—A charter is stated to have been granted to the Greenfield, Deerfield & Northampton St. Ry. Co., with a capital of $20,000. Directors: J. B. Bridges, W. W. Sanderson, and others.

Haverhill, Mass.—The Aldermen are stated to have granted the Haverhill & Southern New Hampshire St. Ry. Co. a location from Winter through Locust and Granite Sts. to the Boston & Maine depot. The company will build a stone arched bridge on Locust St. over Little River and block pave Granite St. at a cost of $7,000. F. Woodman, Mgr., Haverhill.

Waltham, Mass.—The Newton St. Ry. Co. is stated to have petitioned the Aldermen for a franchise to extend its tracks up Main St. to the western line. The company is also reported to have decided to extend its line through Weston Junction to Concord.

Winchester, Conn.—Henry W. Soule, of Tollard, Mass., is reported interested in the construction of an electric railway through Winchester and Colebrook, Conn., and Tolland, Sandisfield, Otis, Becket, and Lee, Mass.

Derby, Conn.—The Bd. of Aldermen is stated to have granted permission to the Fair Haven & Westville Co. (L. A. Farnham, Ch. Engr., New Haven) and the Connecticut R. R. & Lighting Co. (J. E. Sewell, Gen. Mgr., Bridgeport) to complete the extension from New Haven to Derby.

Newport, R. I.—The City Council is stated to have granted a franchise to the Newport & Bristol Ferry Ry. Co. to lay rails and operate cars in Newport.

Trenton, N. J.—It is stated that the Trenton St. Ry. Co. will soon install in its power house on Lincoln Ave. a $1,500 H.-P. engine and dynamo. H. C. Moore, Mgr., Trenton.

Duncannon, Pa.—The Perry County St. Ry. Co. is stated to have secured a right of way in Duncannon.

Pennington, N. J.—The Trenton, Pennington & Hopewell Traction Co., which is a branch of the Trenton St. Ry. Co., is stated to have secured a franchise from the Hopewell Township Com. to construct a trolley road through Pennington.

Bellwood, Pa.—Judge M. Bell is stated to have granted the Logan Valley Ry. Co. permission to construct an electric railway in Bellwood.

Odessa, Del.—The Town Council is stated to have granted a franchise to A. E. Tennis, of Philadelphia, Pa. The company he represents proposes constructing a line between Odessa and Middletown.

Syracuse, N. Y.—The Rapid Transit Ry. Co. has petitioned the Council for a franchise to extend the University line through S. Crouse Ave. and University Pl. to connect with the present tracks in Walnut Ave. C. F. Stierly, Ch. Engr., Syracuse.

McKeesport, Pa.—It is stated that the Pittsburg Rys. Co. will expend about $25,000 in improvements in McKeesport. F. Uhlenhaut, Ch. Engr., Pittsburg.

Pittsburg, Pa.—The Morningside St. Ry. Co. is stated to have petitioned the Council for a franchise. The company proposes to construct a line from Stanton Ave. and Negley to connect with the lines of the Pittsburg Rys. Co. on Butler St.

Murrysville, Pa.—A company is reported incorporated to construct a street railway from Trafford City to Murrysville, a distance of about 7 miles. W. S. McClure and Calvin Good, of Murrysville, are reported interested.

West Grove, Pa.—The West Chester St. Ry. Co. is stated to have secured a franchise from the Boro. Council. C. V. Mills, Supt., West Chester.

Wilmington, Del.—The St. and Sewer Dept. is stated to have granted the Union Ry. Co. permission to extend its 2d St. line.

New York, N. Y.—The contract for the construction of that part of the Brooklyn branch of the subway system from Bridge St., in Manhattan, under the East River, to a point near Clinton St., in Brooklyn, has been awarded by the Rapid Transit Subway Construction Co. to Andrew Onderdonk, 80 B'way.

Youngstown, O.—It is stated that the Youngstown & Southern Ry. Co., which is about to build an electric line from Youngstown to Columbiana proposes extending the line across Columbiana County to connect Columbiana, Leetonia, Salem, Lisbon, and East Liverpool. Gen. Asa W. Jones, John H. Ruhlman and J. E. Long, of Youngstown, are reported interested.

Boonville, Ind.—The Evansville, Boonville & Rockport El. Ry. Co. is stated to have secured a right of way in Warrick County.

Honeycreek, Ind.—The directors and stockholders of the Southern Indiana Ry. Co. are stated to have decided to build an extension known as the Terre Haute Belt line, from Honeycreek; also, to build branch roads in the counties of Clay and Vigo, none to exceed in length 50 miles.

Newcastle, Ind.—The Town Bd. is stated to have granted a franchise to the Indianapolis & Eastern Interurban Electric Ry. on Main St., from Bway, south. The line will be built from here to Dunreith, where it will connect with the main line.

Urbana, O.—The Champaign Co. Comrs. are stated to have granted a franchise to the Urbana, Bellefontaine & Northern Traction Co., and an extension of 7 months' time in which to complete the electric road between Urbana and West Liberty.

Winton Place, O.—The Council is stated to have granted the Cincinnati Traction Co. permission to make extensions through the eastern part of the village. J. R. Welzenecker, Ch. Engr., Cincinnati.

Chicago, Ill.—The Judiciary Com. of the Co. Bd. is stated to have recommended for passage an ordinance granting the Chicago, Milwaukee Ave. & Inland Lakes Traction Co. permission to construct and operate a trolley line on Milwaukee Ave. from the city limits to the Cook County line.

East Liverpool, O.—The Columbiana Central Electric Ry. Co. has been incorporated with a capital of $10,000 to construct and operate an electric railway from East Liverpool, through Lisbon to Salem, O. Incorporators: E. J. Miller, D. J. Ryan, and others. Headquarters of the company is at Columbus.

Cincinnati, O.—The Bd. of Pub. Service is stated to have granted the Cincinnati Traction Co. permission to extend the Gilbert Ave. and East End Routes. J. R. Welzenecker, Ch. Engr., Cincinnati.

Shawano, Wis.—The City Council is stated to have granted the Shawano & Green Bay Traction Co. a franchise through Shawano.

Sparta, Ill.—J. E. Wilson is stated to have petitioned the City Council for a franchise to construct and operate a street railway in Sparta.

Paoli, Ind.—The Town Council is stated to have granted a franchise to the New Albany, Paoli & French Lick Traction Co.

Wabash, Ind.—The Council has granted a franchise to Henry Law, to build an electric railway to Marion; also a franchise to the Rochester & Wabash El. Ry. to build to Rochester.

Mankato, Minn.—U. P. Hord, of Aurora, Ill., and F. G. Keator, of Chicago, Ill., are stated to have petitioned the Council for a franchise for a street railway through the city on the principal business streets.

Pascagoula, Miss.—S. S. Bush, of Louisville, Ky., is reported interested in the construction of an electric railway between Pascagoula and Moss Point.

Newton, Kan.—It is stated that the Union Electric Ry. & Construction Co., of Wichita, has petitioned the Harvey Co. Comrs. for a right of way for an electric railway it proposes constructing between McPherson and Arkansas City.

Louisville, Ky.—The directors of the Louisville Ry. Co. are stated to have decided to build an electric railroad from Louisville to Jeffersontown. F. M. Miller, Ch. Engr., Louisville.

Oklahoma City, Okla. Ter.—The Oklahoma Traction Co., of Oklahoma City, has been incorporated, with a capital of $2,000,000, to construct and operate a railway from Guthrie via Oklahoma City to Ft. Reno, a distance of 75 miles. Incorporators: John Shartel and M. L. Spitlock, of Oklahoma City; U. C. Guss, of Guthrie, and others.

Guthrie, Okla. Ter.—The Guthrie Light & Traction Co., of Guthrie, has been incorporated, with a capital of $500,000, to construct an electric railway in Guthrie. Incorporators: John Shartel, Oklahoma City; F. H. Greer and W. H. Mertens, of Guthrie.

Nashville, Tenn.—The new owners of the Nashville Ry. are stated to have drawn up plans calling for the expenditure of $2,379,000 on the street railway and electric-light plant, the latter being also owned by the same men.

Ritzville, Wash.—Col Lunceford and P. R. Clark, of Ritzville, are stated to have petitioned the Adams Co. Comrs. for a franchise for the construction of an electric railway and the transmission of electric power.

San Francisco, Cal.—The San Francisco, Oakland & San Jose Electric Ry. Co. has been incorporated, with a capital of $5,000,000, to construct an electric railway from San Francisco to Oakland, Haywards, San Jose, Santa Clara and Los Gatos, a total distance of 93 miles. Directors: F. M. Smith, F. C. Havens, E. C. Hearon, and others.

Santa Cruz, Cal.—The Superv. are stated to have granted Fred W. Swanton a franchise to construct an electric railway from Santa Cruz to Capitola.

Vallejo, Cal.—It is stated that bids will be received by the Clk. of Co. Superv. Jan. 2 for the purchase of an electric road franchise along certain roads in Suisun, Green Valley, Vacaville and Silveyville Townships. J. W. Hartzell has petitioned for the franchise.

RAILROADS.

Windsor Locks, Conn.—A press report states that the New York, New Haven & Hartford R. R. Co. has begun preliminary steps for extensive improvements and changes in its roadbed, whereby the road between this place and Springfield will be shortened about ½ mile and a dangerous curve eliminated. The plans include the erection of a steel bridge across Connecticut River, between Windsor Locks and Enfield. The improvements will probably cost, it is said, about $1,000,000. C. M. Ingersoll, Jr., Ch. Engr., New Haven.

Philadelphia, Pa.—Local press reports state that $200,000,000 will be spent by the Pennsylvania R. R. and the companies which are parts of the Pennsylvania system, during the next 2 years, in improving and requipping the trunk lines and branches, building new tunnels, etc. W. H. Brown, Ch. Engr., Philadelphia.

Waynesburg, Pa.—A corps of engineers of the B. & O. R. R. Co. are about to commence surveying for a line to be constructed from Waynesburg to Uniontown, through the Connellsville coke region. J. M. Graham, Ch. Engr., Baltimore.

West Brownsville, Pa.—A charter has been granted to the Pennsylvania, Monongahela & Southern R. R. Co. to build a link from West Brownsville, on the Pittsburg, Virginia & Charleston, to a point near the mouth of Little Whiteley Creek, Greene County; total distance about 22 miles. Jas. Neale and others interested in Brown & Co., Iron Mfgrs., of Pittsburg, are reported interested.

Ronceverte, W. Va.—It is stated that surveys have been made for a railroad to run from Ronceverte to Lewisburg, W. Va., 6 miles distant. Dabney C. T. Davis, Jr., Pres., Lewisburg.

Richmond, Va.—The Chesapeake & Western R. R. Co. is stated to have received permission to increase its capital from $1,000,000 to $2,700,000. The promoters intend soon to build eastwardly to deep water on Chesapeake Bay. E. H. Jackson, Gen. Supt. Harrisonburg, Va.

Ashland, Ky.—The Kentucky & West Virginia R. R. Co. is stated to have completed a survey from Ashland up the Rockcastle valley to Inez, and embracing the Elkhorn coal regions.

Geneva, Ala.—A charter has been granted to the Geneva R. R. Co., with a capital of $100,000, to build and operate a line from Geneva to Chancellor to connect with the Central of Georgia's Chattahoochee and gulf branch; the distance is 11 miles. Incorporators: W. W. Barnett, J. J. Morris and others.

Guthrie, Okla. Ter.—The City Council is stated to have granted the Denver, Enid & Gulf R. R. Co. a right of way through West Guthrie.

The Central Oklahoma Union Depot & Terminal R. R. Co. has been incorporated, with a capital of $5,000,000, to erect union depots at Guthrie and Oklahoma City, and construct belt lines in these cities and to build 150 miles of railroad in Central Oklahoma.

Ashdown, Ark.—It is reported that the Arkansas & Choctaw R. R. Co. will extend its line from Ashdown to Lawton, Okla. Ter. F. W. Valliant, Ch. Engr., Rocky Comfort, Ark.

Little Rock, Ark.—The Arkansas, Red River & Paris R. R. Co. has been incorporated, with a capital of $266,000, to construct a railroad about 38 miles in length. Directors: W. A. Carroll, Nena; A. D. Moon and W. S. Pryor, of Kansas City, Mo., and others.

Articles of incorporation have been filed with the Sec. of State by the Arkansas, Red River & Paris R. R. Co., with a capital of $266,000, to construct a railroad from Morris Ferry, in Little River County, westward into Ind. Ter., to Harris Ferry, on Red River, a distance of 38 miles. Directors: W. A. Carroll, Mena, Ark.; A. D. Moon and W. S. Pryor, Kansas City, Mo., and others.

Piggott, Ark.—The Piggott & Northwestern R. R. Co. has been incorporated, with a capital of $50,000 to construct a railroad from Piggott to the Cache river bottom, a distance of about 12 miles. Directors: F. G. Taylor, Jonesboro; J. M. Myers, R. J. Goeppinger and others, of Piggott.

England, Ark.—The England Clear Lake R. R. Co. has been incorporated, with a capital of $30,000, to construct a railroad from a point in Lonoko Co. to Lasters Landing, a distance of about 9 miles. Directors: J. E. Hicks, N. B. Beakley and others.

Durham, Cal.—The Butte Co. Superv., at Oroville, are stated to have granted the Diamond Match Co. a franchise to construct a railroad from its timber holdings on Magalia ridge to Durham.

PUBLIC BUILDINGS.

Boston, Mass.—Bids will be received Nov. 28 by the Trus. of the Mass. Hospital for Epileptics, at the office of Kendall, Taylor & Stevens, Archts., 93 Federal St., for heating and plumbing of Nurses' Home, now being erected at Monson, for the above institution, and for steam piping and connections for an electric building at the same place. Wm. M. Bullard, Chmn.

SCHOOLS.

Boston, Mass.—The School House Comrs. have under consideration the following bids for the erection and completion of a grammar school on Norman St., at the West End; J. W. Bruty, $275,400; S. Brennan & Co., $295,486; C. H. Belledeau & Co., $289,975; Conners Bros., $293,000; H. P. Cummings & Co., $291,000; C. H. Dodge, $290,897; A. Fales & Sons, $266,800; John J. Flynn, $298,380; Morrill & Whiton Const. Co., $289,670.95; Henry McGahey, $286,000; Mack & Moore, $267,900; Mead, Weston & Co., $314,250; Norcross Bros., $305,875; Whidden & Co., $297,810; Wheaton Bldg. & Lumber Co., $269,000; Goodwin & Wester, $263,949. Bidders all of Boston.

Bids will be received Dec. 1 by the Schoolhouse Comrs. for erecting a primary school, in Martin Dist., Huntington Ave. and Kenwood Road, exclusive of heating, plumbing and electrical work, requiring a bond of $25,000. Wheelwright & Haven, Archts.; R. Clipson Sturgis, Chmn.

Greenfield, Mass.—Gardner & Grahm, of Springfield, are the architects for proposed alterations to High School, to cost $25,000.

Ravenswood, L. I. City, N. Y.—Bids will be received Dec. 1 by C. B. J. Snyder, Supt. of School Bldgs., New York, N. Y., for erecting school No. 83 on Vernon Ave., Boro. Queens.

Philadelphia, Pa.—Bids will be received Nov. 25 by the Com. on Property for erecting 2 schools, 1 at Morris and Moyamensing Ave. and the other at 63d St. and Elmwood Ave. A. F. Hammond, Secy. Bd. of Educ.

Brooklyn, N. Y.—The following bids were opened Nov. 17 by C. B. J. Snyder, Supt. of School Bldgs., Dept. of Educ., New York City, for the general construction of addition to and alterations in School 123, Boro. of Brooklyn: *a*, to complete Sept. 1, 1903; *b*, to complete Jan. 1, 1904: Myron C. Rush, *a*, $156,945; *b*, $149,945. John Auer & Sons, *a*, $149,000 (awarded); *b*, $142,575. Geo. Hildebrand, *b*, $151,889. John H. Goetschius, *a*, $150,000; *b*, $150,000. Peter Cleary, *b*, $150,000. Tolmie & Kerr, *b*, $146,756. Wm. P. McGarry, *b*, $146,371. Chas. H. Peckworth, *b*, $144,445. Wm. & Thos Lamb, *b*, $148,000.

Richmond, L. I., N. Y.—Bids will be received Dec. 1 by C. B. J. Snyder, Supt. of School Bldgs., New York, N. Y., for alterations and additions to the ventilating and heating apparatus for school No. 16, Madison Ave., New Brighton, Boro. Richmond.

Pittsburg, Pa.—The Congregation of the Holy Family R. C. Church (Rev. A. Smelox, Pastor) is reported to be making arrangements to erect a school, at a cost of $35,000.

Yonkers, N. Y.—A. B. Barr & Co., 67 Dock St., are stated to have secured the contract for the heating and lighting apparatus for the High School addition, for $4,967.

Marion, Ind.—The High School is reported to have been destroyed by fire Nov. 16.

Racine, Wis.—The Finance Com. of Council is stated to have decided to issue $80,000 bonds for enlarging and improving the schools.

Milwaukee, Wis.—The Bd. of Aldermen is reported to have decided to erect a $75,000 school in the 1st Ward, and has recommended the issue of $150,000 bonds for a high school on the north side.

Forest, O.—City Clk. Harry E. Moore writes that at the recent election it was voted to issue $20,000 bonds for the construction of a school.

Two Rivers, Wis.—The citizens are stated to have voted to issue $35,000 bonds for the erection of a new school.

Rutland, Ill.—It is stated that plans have been prepared for a $20,000 school.

Lexington, Ky.—The citizens are reported to have voted to issue $75,000 bonds for the erection of 3 schools.

Paola, Kan.—It is stated that the Ursuline Sisters will erect a $35,000 academy here.

Stockton, Cal.—The Bd. of Educ. has rejected all bids for the High School as being too high, and contemplate changing plans to bring cost inside of $100,000; lowest bid was $120,000.

Guelph, Ont.—Schultz Bros. Co., Brantford, are stated to have secured contract for erecting the Macdonald Institute at the Agricultural College, Guelph. This is one of the two buildings which are being erected from a gift of $125,000 by Sir Wm. Macdonald, of Montreal, Que.

STREET CLEANING AND GARBAGE DISPOSAL.

New York, N. Y.—The only bid received Nov. 21 for the removal of snow and ice in Manhattan Boro. was that of Wm. Bradley, 534 W. 48th St., at 30 cts. per cu. yd.

Reading, Pa.—Geo. W. Beard & Co. have received the contract for the erection of a plant for the Reading Sanitary Reduction Co., to be located on the farm of Chas. Fischer, in Cumru, near the County Home. Mr. Fischer was given the garbage contract recently by the city for 5 years, and it will be handled by this Co.

St. Paul, Minn.—The Com. on Streets has approved a resolution to expend $40,000 for street sprinkling.

Sandusky, O.—According to local press reports Wm. F. Seitz, Jr., is at the head of a local Co. which proposes to erect a garbage disposal plant in this city, at a cost of $30,000 to $40,000. The Co. will be a branch of the Waste Utilization Co. of New Jersey.

Kansas City, Mo.—Local press reports state that bids will be opened Dec. 19 by the Special Garbage Com. of Both Houses of the Council for collecting and disposing of the city's garbage. Dr. Langsdale, City Physician.

Seattle, Wash.—The Bd. of Health recommends the construction of a crematory for the disposal of city garbage, and the proposition to issue bonds for same may be voted upon at the next special election.

GOVERNMENT WORK.

Baltimore, Md.—Bids are wanted at the U. S. Engineer Office until Dec. 17 for dredging in Curtis Bay, Md., as advertised in The Engineering Record.

Buffalo, N. Y.—The following bids were opened Nov. 17 at the Treasury Dept., Washington, D. C., for the construction of a shed over driveway at mailing entrance of the U. S. Post Office, Buffalo: Master & Summers, Buffalo, $15,500; J. R. Churchyard, Buffalo, $11,284; A. B. Stannard, New York, N. Y., $11,467.

New York, N. Y.—Lt. Col. C. W. Raymond, Corps of Engrs., U. S. A., writes that the lowest bids received Nov. 13 for dredging were as follows: The International Contracting Co., New York, N. Y., 23½c. cu. yd. for Keyport Harbor and Matawan Creek, and 35c. cu. yd. for South River; E. R. Seward, New York, N. Y., 30c. cu. yd. for Raritan River; Kirk, Driscoll & Co., Syracuse, N. Y., 35c. cu. yd. for South River; 35c. cu. yd. for Elizabeth River, and 30c. cu. yd. for Shoal Harbor and Compton Creek; John & Joseph McSpirit, Jersey City, N. J., 25c. cu. yd. for South River.

Bids were also received Nov. 10 by Lt.-Col. C. W. Raymond for dredging, the bid recommended for award in each case being as follows: Lemon Creek, N. Y., Duncan J. Currie, Perth Amboy, N. J., at 19c. per cu. yd. prism measurement; Woodbridge Creek, N. J., Newburgh Dredging Co., Newburgh, N. Y., at 20c. per cu. yd. scow measurement; Raritan Bay, N. J., R. G. Packard Co., New York, N. Y., at 16c. per cu. yd. scow measurement.

The following bids were opened Nov. 15 at the Bureau of Yards and Docks, Navy Dept., Washington, D. C., for removing from 90,000 to 140,000 cu. yds. of material from waters of Navy Yard, New York; prices are per yd. scow measurement: R. G. Packard Co., New York, 33½c.; International Const. Co., New York, 54c.; Morris & Cumings, New York, 57c.

Wilmington, Del.—Bids are wanted Dec. 15 for construction of jetty at mouth of Mispillion River. Col. Jared A. Smith, Corps Engrs., U. S. A.

Savannah, Ga.—Bids are wanted Dec. 22 at the U. S. Engr. Office for building training dikes in Savannah River, near Augusta, Ga., as advertised in The Engineering Record.

Milwaukee, Wis.—Bids are wanted at the U. S. Engineer Office until Dec. 18 for constructing concrete superstructure on breakwater and on North Harbor Pier, at Milwaukee Harbor, Wis., as advertised in The Engineering Record.

Chicago, Ill.—The Secy. of the Treasury has awarded to John Peirce, of New York, the contract for the interior finish of Chicago Post Office, at his bid of $997,500, reserving the right to improve the finish if additional money is appropriated by Congress for that purpose.

St. Louis, Mo.—The contract for erecting and completing the U. S. Government Bldg., at the Louisiana Purchase Exposition, is stated to have been awarded to W. O. & C. G. Burton, of Richmond, Va., for $268,980.

Chilocco, Okla. Ter.—Bids are wanted Dec. 11 for furnishing material and erecting a stone dormitory and an addition to a dormitory, including steam heat, electric light and plumbing, at the Chilocco school. Address A. C. Tonner, Acting Comr. of Indian Affairs, Washington, D. C.

Laredo, Tex.—A correspondent writes that the Treasury Dept. has purchased a site at $11,000 for the U. S. Custom House. Appropriation, $150,000.

Memphis, Tenn.—Local press reports state that contracts will be let in April, by the Treasury Dept., Washington, D. C., for building the $250,000 addition to the Federal Bldg. in Memphis.

Dover, Tenn.—Bids are wanted Dec. 13 for constructing roadway to National Cemetery. C. D. V. Hunt, Q. M.

Mobile, Ala.—Bids are wanted Dec. 17 for furnishing material for repairing and extending depot wharf at Egmont Key Light Station, Fla. Lieut.-Col. A. N. Damrell, U. S. A., Light-House Engr., Mobile.

Ft. Meade, S. D.—The contracts for constructing brick barracks at Ft. Meade, is reported to have been awarded to Burns & Schummer, of Sturgis, S. D., for $48,611; and the contract for electric wiring to S. O. Oliver, of Sturgis, for $950. New bids will be asked for the plumbing and heating apparatus.

San Francisco, Cal.—The following bids were opened Oct. 16 by Lieut. R. P. Johnston, Corps of Engrs., U. S. A., for building portions of dam, known as Barrier No. 1, on Yuba River, about 14 miles above Marysville, Cal.:

Bidders and Addresses.	50,000 lin. ft. Wakefield sheet piles.	Placing 3,130 Wakefield sheet piles.	13 M ft. B. M., capping.	2,333 sq. yds. brush mattress.	1,500 sq. yds. brush protection. MISCELLANEOUS.

Syracuse, N. Y.—Bids are wanted Nov. 25 for $50,000 Onondaga Creek improvement bonds. E. J. Mack, Compt.

New York, N. Y.—Bids will be received Nov. 26 by Thos. W. Hynes, Comr. of Correction, for furnishing and delivering iron, steamfittings, electrical supplies, etc.

Atlantic City, N. J.—The Council has appropriated $80,000 for boardwalk purposes.

Albany, N. Y.—The Flood Com. of the Chamber of Commerce has made the following recommendations to the State Water Storage Comn., for preventing floods: the establishment of a system of storage reservoirs on tributaries of the Hudson, and the improvement of the Hudson River channel so as to prevent the possible formation of ice gorges.

Buffalo, N. Y.—Local papers quote Comr. of Pub. Wks., Col. Ward, as having stated that the cost of improving Buffalo River, including the deepening of river, acquirement of lands necessary for improvement and the placing of flood-gates on sewers, will cost about $1,500,000, and contract will probably soon be let.

Glens Falls, N. Y.—Repairs to the Glens Falls feeder and Champlain canal at Glens Falls, Ft. Edward and Moses Kill, to cost about $30,000, have been authorized by the Supt. of Pub. Wks., Albany.

Baltimore, Md.—The contract for the new pier to be erected at Curtis Bay by the B. & O. R. R. has been awarded to A. R. Morrison, of Wilmington, Del., for $450,000, to be completed in 10 months; length to be over 800 ft.

The B. & O. R. R. has applied for a permit to erect a corrugated iron shed, 794 ft. long and 138 ft. wide, on its proposed import and immigrant pier at Locust Point, to cost $180,000.

Augusta, Ga.—The City Council has voted to borrow not exceeding $100,000 to construct a levee on the river bank from 15th to 9th Sts., capable of keeping out the water of Savannah River of a 36-ft. rise.

Columbus, O.—Bids will be received Dec. 9 by the State Bd. of Pub. Wks. for constructing concrete walls, on stone masonry, along water lines of canal between Liberty St. and Queen City Ave., and between 14th and 15th St. Chas. E. Perkins, Ch. Engr., Pub. Wks.

Chicago, Ill.—Bids will be received Jan. 14 by A. R. Porter, Clk. of Sanitary Dist., for dredging the main and the south branch of Chicago River, and docking that portion of river front contiguous to the portions dredged, together with other work relating thereto. Thos. A. Smyth, Pres.

San Diego, Cal.—Samuel Parsons, Jr., of New York City, is stated to have been engaged by the city to prepare plans for beautifying 1,400 acres of city park.

NEW INDUSTRIAL PLANTS.

Henry L. Norton, Springfield, Mass., engineer and contractor for steel bridges, buildings, girders, etc., is building a 40x100-ft. shop, together with blacksmith shop and sheds. The capacity will be about 100 tons per month.

Findlater & Copeland, San Angelo, Tex., are excavating the cellar for a 2-story, 50x100-ft. concrete building, the ground floor to be used for blacksmithing and woodworking machinery and the upper story for buggy and carriage salesroom, etc. A machine shop and foundry may be installed later.

The Hockensmith Wheel & Mine Car Co., Irwin, Pa., has contracted for the steelwork for a 228x60-ft. foundry and machine shop; 178x50-ft. blacksmith and wagon shops; 2-story, 125x30-ft. pattern shop and an 80x25-ft. power house. The power plant will have a capacity of about 150 H.-P.

The Susquehanna Silk Mills, which have a large weaving mill in Sunbury, Pa., will erect next spring in the same place a piece dyeing and finishing establishment. It will be a one-story structure about 300 ft. square, and is to be equipped with the best and most modern machinery. The New York office is at 62 Greene St.

The Richmond, Ind., Handle Co. is building a 40x80-ft. factory. A 70-H.-P. boiler and 60-H.-P. engine will be installed. J. A. Greenstreet, New Castle, Ind., Secy.

Thos. J. Lillard, Elkin, N. C., desires prices on hosiery mill machinery.

The Eagle Shoe Co., Newport News, Va., capital $100,000, proposes to build a factory. V. M. Fleming, Pres.

The Gladiator Consolidated Gold Mines & Milling Co., Iowa Loan & Trust Bldg., Des Moines, Ia., will erect a mill and reduction works having a daily capacity of 200 tons on the Gladiator group and a 100-ton plant on the Red Cloud Group.

The Deshler, Neb., Broom Co. will erect a 2-story, 50x300-ft. factory and install a power plant of 40 to 50 H.-P.

BUSINESS NOTES.

The Richardson Scale Co., 21 Park Row, New York, announces that it is prepared to manufacture and sell Richardson automatic scales in the United States. These scales have been manufactured in Great Britain for a number of years, and are adapted for weighing coal, cement, sugar and similar materials.

The Salisbury Steel & Iron Co., Utica, N. Y., has been incorporated with a capital of $1,000,000. The directors are: Geo. M. Bard, Wilmington, Del.; Harvey L. Atkins, Wm. W. Hearne, Philadelphia; Wm. Kerby, New York; Henry N. Clark, Boston; Victor Adams, Little Falls, and Wm. H. Switzer, Utica.

The Ball Engine Co., Erie, Pa., reports the following among recent orders: Penna. R. R. Co., 450 H.-P. engine for the Altoona shops and 250-H.-P. at the Meadows, N. J., shop; 250-H.-P. engine for the American Sugar Refining Co., Jersey City, N. J.; an engine for the Bishop & Babcock Co., Cleveland; engines for the Western Packing Co., Denver, Col., direct connected to two 100-Kw. Crocker-Wheeler generators.

The Kennedy Valve Mfg. Co., New York, has completed an order for the Boston Navy Yard for a large lot of valves and over 100 of its underwriters' approved weather-proof adjustable indicator posts for automatic sprinkler systems.

The National Drill & Mfg. Co., 159 La Salle St., Chicago, has been incorporated with a capital of $500,000, and is installing machinery in its plant at Barberton, O. Road machinery will be included in its manufactures. E. R. Stettinius, of the Stirling Boiler Co., is president; Arthur Cameron, former sales manager for the Austin Mfg. Co., is vice-president and general manager, and O. C. Barber, of the Diamond Match Co., is among its financial backers.

The New York Continental Jewell Filtration Co., New York, reports receiving an order for a large gravity filter plant for the Northern Hospital for the Insane at Winnebago, Wis., and from the Chicago & Eastern Illinois Ry. for plant for purifying water for boiler use at its Kinmundy, Ill., station.

The Park Mfg. Co., Chicago, has been incorporated, with a capital of $250,000, for manufacturing in iron and steel. The incorporators are: George N. and Frank H. Lyman and George D. Bardon.

The Indiana Asphalt Co., Chicago, has been incorporated, with a capital of $300,000, to manufacture asphalt. The incorporators are: Alexander G. Warren, R. W. Barnes and Arthur Griffin.

The Allis-Chalmers Co., Chicago, reports the following among its sales of Reynolds-Corliss engines during October, 1902: Indiana Rolling Mill Co., Newcastle, Ind., a 26x48 and a 28x48-in.; Scott & Van Arsdale Lumber Co., McCloud, Cal., a 26x48-in.; Downie-Wright Mfg. Co., York, Neb., a 12x36-in.; Kirby Lumber Co., Houston, Tex., a 22x48-in.; Coleman Implement Co., Peoria, Ill., an 18x42-in.; Wyckoff, Seamans & Benedict, Ilion, N. Y., a 14 and 28x30-in.; Chicago Edison Co., 32 and 64x60-in.; Lansing, Mich., Wagon Wks., 16x36-in.; A. C. White, Saginaw, Mich., 22x42-in.; H. R. Johnstone, 16x36-in.; J. L. Lindsay, Richmond, Va., 14x36-in.; International Paper Co., New York, two 22x42-in.; National Tube Co., Pittsburg, six 22 and 42x42-in. and a 44 and 84x60-in. vertical blowing engine; Scott & Van Arsdale Lumber Co., St. Cloud, Minn., 18x42 and 22x42-in.; Minot, N. D., Milling Co., 12x36-in.; Brogon Cotton Mills, Anderson, S. C., 30 and 64x60-in.; Des Moines, Ia., Brick & Tile Co., 18x42-in.; Milwaukee, Wis., Worsted Mills, 20x42-in.; F. E. Kreatz, St. Cloud, Minn., 18x36-in.; Metropolitan Paving Brick Co., Canton, O., 22x52-in.; Booten & Lyne, Orange, Va., 12x30-in.; Euston & Co., Chicago, 18x42-in. engine and a 6x16-ft. boiler; Columbus, O., Milling Co., 14x36-in.; National Biscuit Co., Chicago, 20x36-in.; Carnegie Steel Co., Pittsburg, 48 and 78x60-in. combined horizontal and vertical; D. E. Converse Mfg. Co., Glendale, S. C., a 14x36-in.; New Jersey & Hudson River Ry. & Ferry Co., 28 and 56x48-in. Also an 8,000,000 gal. pumping engine to the city of Milwaukee; Penna. R. R. Co., two 384-H.-P. Sederholm boilers; Theresa Gold Mining Co., 16x30-in. single drum hoist; Compania Minera de Penoles, Mex., a Riedler air compressor, with 14x18-in. steam cylinder and 10½ and 18x18-in. air cylinder.

A New Drafting Machine. (Illustrated)......... 520
Removal of the Old South Tenth Street Bridge, Pittsburg, Pa.............................. 521

The Engineering Record is published every Saturday at 21 Park Row, New York. Its opinions on technical subjects are either prepared or revised by specialists.

Subscriptions are received and single copies supplied by the International News Company, Breams Building, Chancery Lane, London.

The subscription rate is $5 a year for the United States, Canada and Mexico, and $6 for other countries in the Postal Union. Remittances should be made by check, New York draft or money order in favor of The Engineering Record. No responsibility is assumed for payments made otherwise, except those for subscriptions to the International News Company.

Another Proposed Isthmian Canal Route.

The Isthmian Canal Commission, in its report made in 1901, recommended the adoption of the Panama route for a ship canal across the Isthmus. Congress at its last session authorized the President of the United States to cause to be constructed on the Panama route a ship canal of the dimensions and according to the plans recommended by the Isthmian Canal Commission, provided that the New Panama Canal Company could convey a satisfactory title to all its rights and privileges on the Isthmus, and provided the requisite concessions could be secured on satisfactory terms by treaty between the governments of the United States and of the Republic of Colombia. Should the President fail to fulfil either of the stipulated conditions, he was then authorized to enter into negotiations with the Nicaraguan government for the purpose of securing the necessary rights and concessions to construct the ship canal on the Nicaragua route. Inasmuch as treaty negotiations have not yet been satisfactorily concluded with the Colombian government, it is perhaps too soon to reject all consideration of matters pertaining to the Nicaraguan route. At the same time, any data offered in connection with such a consideration should be most carefully scrutinized.

In 1888-1889 Mr. J. Francis LeBaron, M. Am. Soc. C. E., was engaged in engineering examinations on the Maritime Canal Company's project, and the experience and information gained at that time have prompted him to present a paper before the American Society of Civil Engineers on "An Alternative Line for the Nicaragua Canal; and a Proposed New Method of Dam Construction," which appeared in the "Proceedings" of that society for October, 1902. Mr. LeBaron adopts for his purpose practically the Ochoa dam and San Carlos embankment line, but with some different features of construction of the dam of the Menocal project. He proposes, however, a radically different canal line from the dam to the sea, lying on the southerly or easterly side of the San Juan River, with its terminus at the mouth of the Colorado River, 30 miles easterly from Greytown. He recognizes the great volume of sand movement at Greytown with the resulting difficulties and costs of harbor maintenance. At the mouth of the Colorado (which is the main outlet of the San Juan River), the coast line appears to be practically stable, and the real purpose of the proposed alternative line is to reach that point and adopt it for harbor purposes, claiming much reduction in cost of canal between the San Carlos dam and the sea, as well as a far more desirable harbor location.

A careful reading of the paper does not disclose information secured by an actual survey of the proposed alternative line, nor by borings made along it. Some reconnaissances and surface observations had been made over portions of the location, but those are all. In view of the great extent of the survey and boring work done by the numerous parties of the Nicaragua and Isthmian Canal Commissions on both their trial and final lines, it would seem that correspondingly thorough data would be required to determine the merits of any alternative location. The author of the paper states at one point that information which one would naturally suppose to be an important part of the necessary knowledge was obtained "from the high pilot house of a steamer on the San Juan River." When it is remembered that the information gained in that way bears upon the depth of cutting required for the canal and the character of the material to be excavated, it can readily be realized that conclusions based upon such data should be drawn cautiously or rather, not at all.

The conditions at Greytown are certainly most unencouraging for a harbor and the search for some other harbor site is a necessity in the complete consideration of the Nicaragua route; but the alternative line proposed appears to involve very serious difficulties of its own. The Isthmian Canal Commission pointed out a grave obstacle to any location on the right bank, or southerly side, of the San Juan River, viz.: the crossings of the San Carlos and Serapiqui rivers. The author avoids the former by utilizing the old Ochoa dam site and dangerously underestimates the difficulties of the latter. He names eleven crossings of streams made by the Isthmian Canal Commission's lines on the left, or northerly, bank of the San Juan River and compares with them seven crossings, including the San Carlos and Serapiqui rivers, on the right, or southerly side, thus showing four less on the latter. He fails, however, to observe that the total volume of discharge of the eleven streams is so much smaller than that of the Serapiqui alone as to be practically insignificant in comparison with it. According to the report of the Isthmian Canal Commission, the flood discharge of the Serapiqui is considerably larger than 26,000 cubic feet per second. Coupling the difficulty of such a crossing by a ship canal with the fact that essentially all exact data on which estimates and comparisons of features must be based are lacking, it is apparent that the proposed alternative has not yet reached a stage of very clear definition as to its value. Nothing short of a complete survey of an entire line with borings to establish positively the character of the materials to be dealt with will determine whether a portion of the proposed canal route is worthy of serious consideration. Anything less than that is too uncertain and too speculative to be considered in comparison with the more reliable data obtained on other locations.

Another grave objection, indeed fatal objection, to the proposed alternative line is the stone-fill dam at Ochoa. Such a structure has been sufficiently discussed in other engineering publications to make it inadvisable to prolong that discussion here. Whether that type of dam properly designed may not legitimately be adopted for some locations is doubtless an open question, but it certainly is not a suitable type of structure for the San Juan River at Ochoa, nor is Ochoa the proper location for a dam having for its purpose the extension of the lake level along the river. It would be exceedingly injudicious to attempt at all to hold the flood waters of the San Carlos with all the sediment carried by them; they should have free passage down the San Juan. The virtue of the chain netting proposed is questionable, even if it would not quickly rust away in the waters of a tropical river. It still appears not unlikely that the investigations of the Isthmian Canal Commission have settled all the main features of the Nicaragua route so completely as to leave little need for consideration of other than secondary or detail studies.

New York Rapid Transit Railroad.

Residents in New York and the strangers in their midst as well have had no need to be told during the last year that the Rapid Transit Railroad would soon be an accomplished fact. A long period of legal controversy has been succeeded by a short period of construction on a scale which has been attempted within the limits of no other city. In a hazy way the history of the work and the plans for the road have been known to the public, yet it is a noteworthy fact that the Board of Rapid Transit Railroad Commissioners never made a comprehensive report until this year, although the commission has existed continuously in one form or another for eleven years. The Board is not required to make periodical reports and the long delay in the publication of any such documents is ascribed officially to the lack of tangible and physical results in which the public would be interested. This absence of any legal requirement making it necessary to print records of its work, and the advantage of this fact which the Board took, may explain the former feeling of many taxpayers that the Commissioners were altogether too independent and secretive. The citizens acquainted with large affairs recognized, however, the shrewdness and public spirit of the members of the Board, and appreciated the necessity of silence in negotiations affecting closely some of the strongest corporations in the city. These years of investigation, legislation and conference with existing railway corporations were really the crucial period of the undertaking, and the completeness with which the Commissioners' acts have at last been published shows their desire to take the public into their confidence fully as soon as the conditions warrant. The record is one of patience, tact and shrewdness which merits a conspicuous place in the city's annals.

While the Board had full power to adopt whatever type of road it judged would afford the greatest advantage, nevertheless the public had to be convinced of the desirability of underground traction because it would sooner or later have to vote to accept or reject the entire project. How well that missionary work was done is shown by the fact that the plans were approved by a vote of 132,647 to 42,916. It was also necessary to secure from the Legislature privileges of an entirely novel sort. "The great object aimed at," Mr. Abram S. Hewitt has said, "was to secure the early completion of the work, its continued ownership by the city, and its reversion at the end of fifty years to the city, free and clear of all incumbrances of every kind and nature whatever." To this end the city's credit had to be extended in a novel manner, already described in The Engineering Record, and the permission to make this use of municipal funds, granted by the Legislature in 1894, is the keynote to the great work now taking place on Manhattan Island. Without it all the skill of the engineer and the diligence of the contractor would be of no avail.

The engineering problems involved in the construction of the road have been described in numerous articles in this journal. The general design was adopted after a careful investigation of all systems of urban railways in the United States and abroad. The question of routes was settled in no small degree by the courts in the course of protracted litigation over other matters. Plans had to be made for extensive modifications of the water and sewerage systems of the city, the change of electric conduits and gas pipes, and the maintenance of conduit electric railways with heavy traffic. Under the most favorable conditions the engineering work would be extremely complicated, but in New York records of underground construction are scanty and confusing. It is impossible to foretell with certainty what obstacles may be encountered in excavating a large trench in any of the leading streets of the city. Consequently the celerity with which construction has progressed and the absence of friction between the engineering department and the contractor make it interesting to notice their respective organizations. This is particularly true when the unsatisfactory experience on the Chicago Drainage Canal is considered.

The staff of Mr. William Barclay Parsons, chief engineer of the Board, is headed by a deputy chief engineer, Mr. George S. Rice. For convenience in superintending the construction, the work was separated into five divisions, each under a division engineer. There is also a general inspector of designs in charge of the preparation of all detail designs and a general inspector of materials. Each division and also the Bureau of Inspection has had an office separate from that at headquarters, with an appropriate force of assistant engineers and inspectors. Of the 118 engineers on the force 100 were graduates of technical schools, Columbia having 27 representatives, much the largest number contributed by any one institution. Even among the 75 rodmen and axemen, 44 out of 75 were graduates.

The contractor's methods are of special interest because this undertaking is the largest municipal contract awarded to a single person, and its progress has been notably rapid when the difficulties of the work are considered. The executive staff embraces a chief engineer, general manager, electrical director, mechanical engineer and car designer, all eminent specialists. The railway was divided into fifteen sections, their points of beginning and ending being fixed by local conditions requiring variations in the construction; and the reconstruction of the most important sewers which had to be changed as a result of the railway was also sublet independently of the sections to which they were related. Some idea of the magnitude of the undertaking may be gathered from the following table of some of the estimated quantities. In connection with these quantities it is interesting to note that although the contractor was given the option of making the working drawings himself, subject to the approval of the Board, or permitting them to be worked out under Mr. Parson's direction, the latter course was adopted, even to the design of the station details. Drawings when thus completed have been forwarded to the contractor, who, in turn, has sent them to the sub-contractor for steel. The latter then prepared the requisite shop drawings, sending them to the contractor, who forwarded them to Mr. Parsons for examination and approval. In this way every drawing has had a double check.

Some of the Quantities on the New York Rapid Transit Railway.

Length, feet	109,570
Underground track, feet	245,514
Elevated track, feet	59,766
Earth excavation, cubic yards	1,700,228
Rock excavation, cubic yards	921,182
Rock tunneling, cubic yards	368,606
Steel work, net tons	65,044
Concrete, cubic yards	489,122
Waterproofing, square yards	775,795

The inspection of materials for this undertaking has demonstrated forcibly how uniform the grade of steel and cement can be maintained when the manufacturer so desires. Out of 1,269 different heats of steel tested in 1900, only 17 were rejected, and out of 3,033 heats tested in 1901 but 12 failed to pass. In the shops, moreover, the manufacture of the steel approached closely to the theoretical limits. The Board's specifications prohibited the weight of finished material from falling below the estimated weights, as computed from the drawings, by more than 2½ per cent., and the contractor, in his arrangement with the American Bridge Company, the sub-contractor for shop work, imposed a similar restriction as to the excess of weight. Up to the present year, the variation of the shipping weights from the estimated weights is only 0.03 of one per cent., this amount being a deficiency.

The record in the matter of cement has been equally interesting. The entire contract for both natural and Portland cement was placed with a single manufacturer, the American Cement Company. As soon as the cement was made it was placed in bins holding about 1,400 barrels each, whence the samples were taken. The material was kept stored in this way until after the completion of 28-day tests, unless rejected sooner. After acceptance it was placed in bags closed with lead seals, and thus shipped. During 1900 42,000 barrels of Portland and 5,000 barrels of natural cement were shipped, and during 1901 the amounts were 148,420 and 10,920 barrels respectively. The results of the briquette tests are given in the accompanying table:

Briquette Tests of Cement.

	1900.	1901.
Portland cement, neat—		
Broken	1,827	15,606
Passed	1,733	15,560
Failed	94	46
Portland cement, sand—		
Broken	726	10,671
Passed	698	10,654
Failed	28	17
Natural cement, neat—		
Broken	411	750
Passed	363	750
Failed	48	...
Natural cement, sand—		
Broken	138	882
Passed	134	882
Failed	4	...

The Board had a laboratory at the cement works, equipped with two testing machines, boiling and steaming apparatus and all other appliances necessary to determine the character of the cement offered for use. In addition to the regular tests to determine properties mentioned in the specifications, various investigations were conducted to ascertain the effect of modifications in the process of manufacture on the quality of the product. In these investigations the manufacturer co-operated heartily and the improvement in the product in 1901 over that in 1900 is doubtless due in a considerable measure to these researches. "The special quality of cement obtained was largely the result," Mr. Parsons states, "of a ruling requiring a specific ratio of increase in tensile strength from 7 to 28 days, and, furthermore, that cement showing as high as 750 pounds at the earlier stage should be generally refused as unlikely to give good practical results in long-time tests."

The Annual Report season is approaching, and so we wish to remind the readers of The Engineering Record that municipal, State and other reports containing items of interest to engineers will be gladly received. Please send your reports promptly.

The Hibernia Building, New Orleans.—II. Superstructure.

The interesting foundations for the Hibernia building, for which Messrs. D. H. Burnham & Company, of Chicago, are architects, and Mr. J. G. Glaver, structural engineer, were described in a recent issue of The Engineering Record. In this article a description of the steel cage superstructure will be given. The building is adjacent to the St. Charles hotel, at Carondelet and Gravier streets, is 82x128 feet and has a basement, twelve stories and an attic.

The angles at the corners of the lot vary from about 79½ to 97 degrees, and on the St. Charles side there is a 29x40-foot open court with its angles varying slightly from right angles. These features prevent the arrangement of all the columns in the same straight lines, and eleven of them are located in two diverging longitudinal rows from about 31 to 46 feet apart between end columns. The intersections of these rows with the building lines are not on the centers of wall columns, and for this reason many of the panels of floorbeams and girders are not rectangular. In the ends of the building the wall columns are closer together than the interior columns, and near the elevator shaft additional columns are interpolated to reduce the long spans between columns at the intersections of the regular rows. These conditions make the framing simple but special, and necessitate the use of unusually heavy girders and floorbeams and some bent plate connections for the long spans and oblique panels.

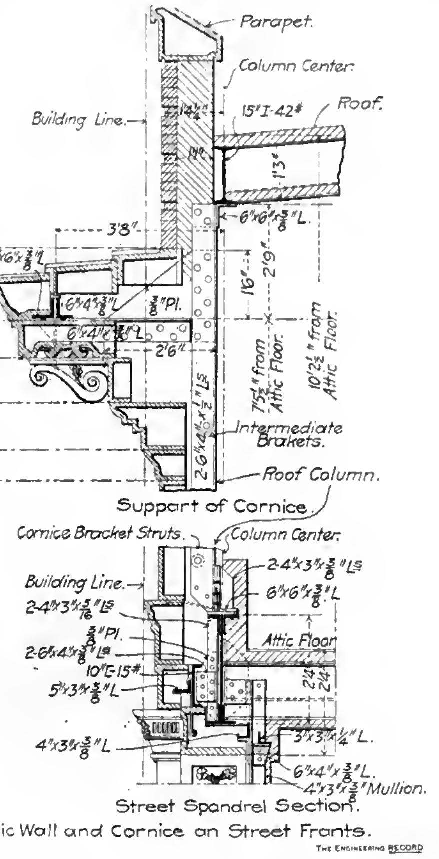
In the typical floors, from the 4th to the 10th stories inclusive, there are in the center of the building two transverse girders, 34 and 37 feet long, which are respectively made with pairs of 24-inch, 100-pound and 24-inch 80-pound I-beams. Adjacent to one of them is a 31-foot plate girder with a 15x7/16-inch web, four 6x6x¾-inch flange angles and two 13x⅝-inch flange cover plates. At the opposite end of the row, in front of the elevator shaft, there is a 40-foot plate girder 28 inches deep; beyond it where the span is still greater intermediate columns are introduced between the longitudinal rows and the girders are reduced to single and double 15-inch I-beams which are used in all other cases in the remaining floor panels. The floorbeams which they support are 12 and 15-inch I-beams, spaced from 5 to 7½ feet apart.

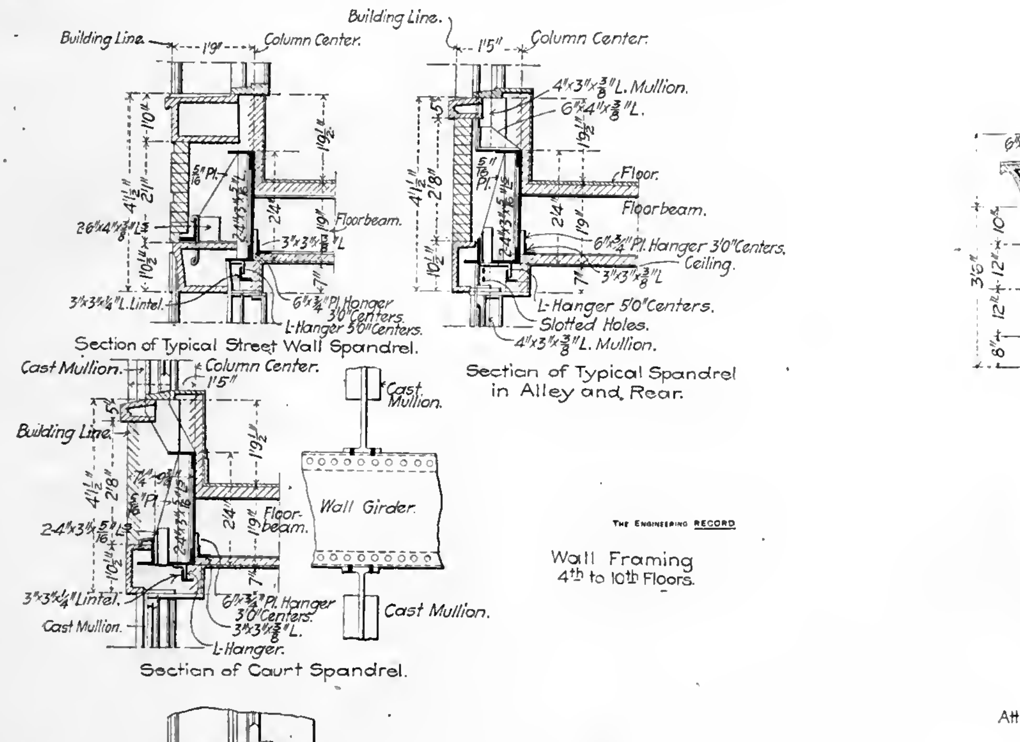
The wall girders carry both the wall masonry and the ends of the floorbeams and have uniformly 28-inch webs in the planes of the centers of the columns, and two 6x4-inch flange angles each, except in one court wall girder which has two 5x3½-inch flange angles. In the party wall between the Hibernia building and the St. Charles hotel the wall girders have four 6x4-inch flange angles, are in the center line of the wall and carry the ends of the beams in the hotel floors. Elsewhere the wall girders are wholly inside the masonry lines, are enclosed by plastering furred out around them, and have, on their exterior faces, solid plate brackets opposite the ends of the floorbeams, which carry a 6x4x7/16th-inch short angle continuous around the exterior of the building to support the terra cotta courses between the windows in successive stories. Where necessary, 3x3-inch horizontal angles are suspended from the wall girders for window lintels and to receive the edges of the floor arches.

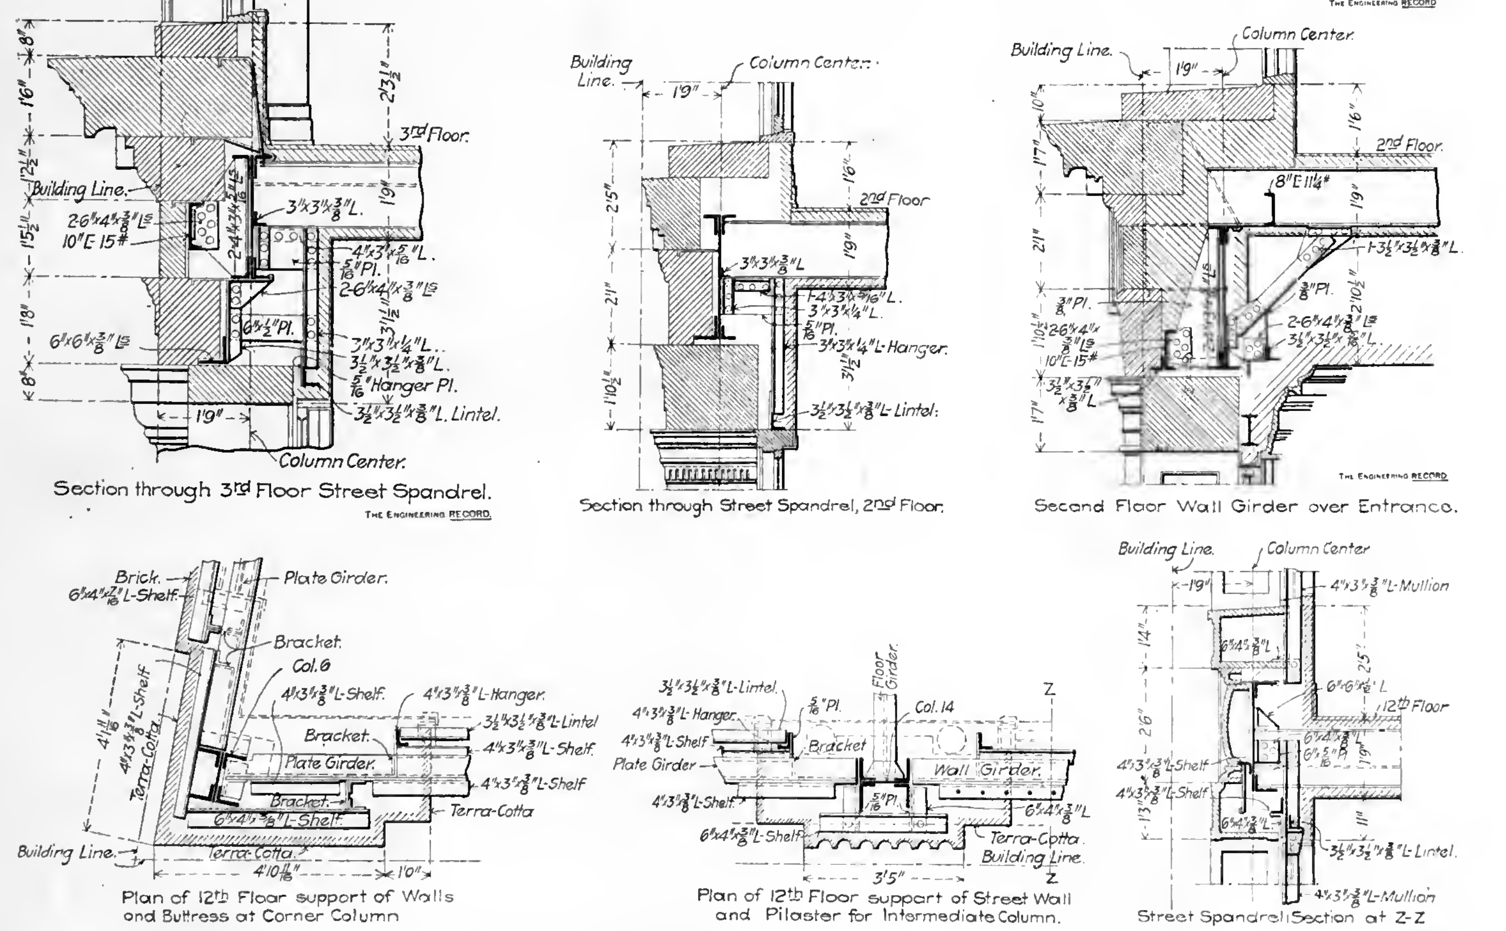
In the alley and rear walls the mullions are single 4x3-inch vertical angles offset nearly a foot from the girder webs. Their feet are riveted to angle brackets projecting across the top flanges of the wall girders, and their upper ends have slotted holes for bolts in similar brackets riveted across the bottom flanges, as shown in the detail cross section of girder and wall. In the light court the mullions are vertical cast iron T-bars with their tops and bottoms bent at an oblique angle so that they can be flange bolted directly to the wall girders. There is a triangular space 40 feet long and nearly 4 feet in maximum width between the elevator girder and the elevator shafts. The ceiling here is dropped about 12 inches below the general height, to enclose the bottom of the girder, and is plastered on the under sides of flat tile arches carried on the lower flange of the 28-inch plate girder and on parallel 6-inch I-beams suspended from other 6-inch I-beams 12 inches in the clear above them, framed into the regular floorbeams.

The arrangement and most of the details in the other floors correspond closely to those in the typical floors, the principal variations being made in the spandrel supports to provide for the architectural treatment of the wall masonry. In the second floor the wall girders in the street fronts are 32 inches deep and their 6x4-inch shelf angles are omitted. Their top flanges are made with two 5x3½-inch angles and the bottom flanges with one 6x6 and one 3½x3½-inch angle, the latter serving for a direct support of one course of solid face masonry. Over the entrance on Carondelet Street, the wall girder is 38 inches deep with four 5x3½-inch flange angles, and partly supports the heavy masonry on a channel and angle bracketed out from its face. The upper courses are anchored back to its top flange and web, which is stiffened to receive them, by knee braces to the floorbeams, as shown in the cross section.

Next to the St. Charles party wall there is a floorbeam about 4½ feet from the wall girder and the space between it in the wall is utilized for a pipe chamber between the floor and ceiling. The pipes are carried by transverse 3x3-inch T-bars resting on the lower flange of the floorbeam and on a 5x3½-inch angle bracketed out from the wall girder web, so as to be clear of the party wall. At the third floor there is a projecting course of stones nearly 4 feet wide which is entirely supported from and an-



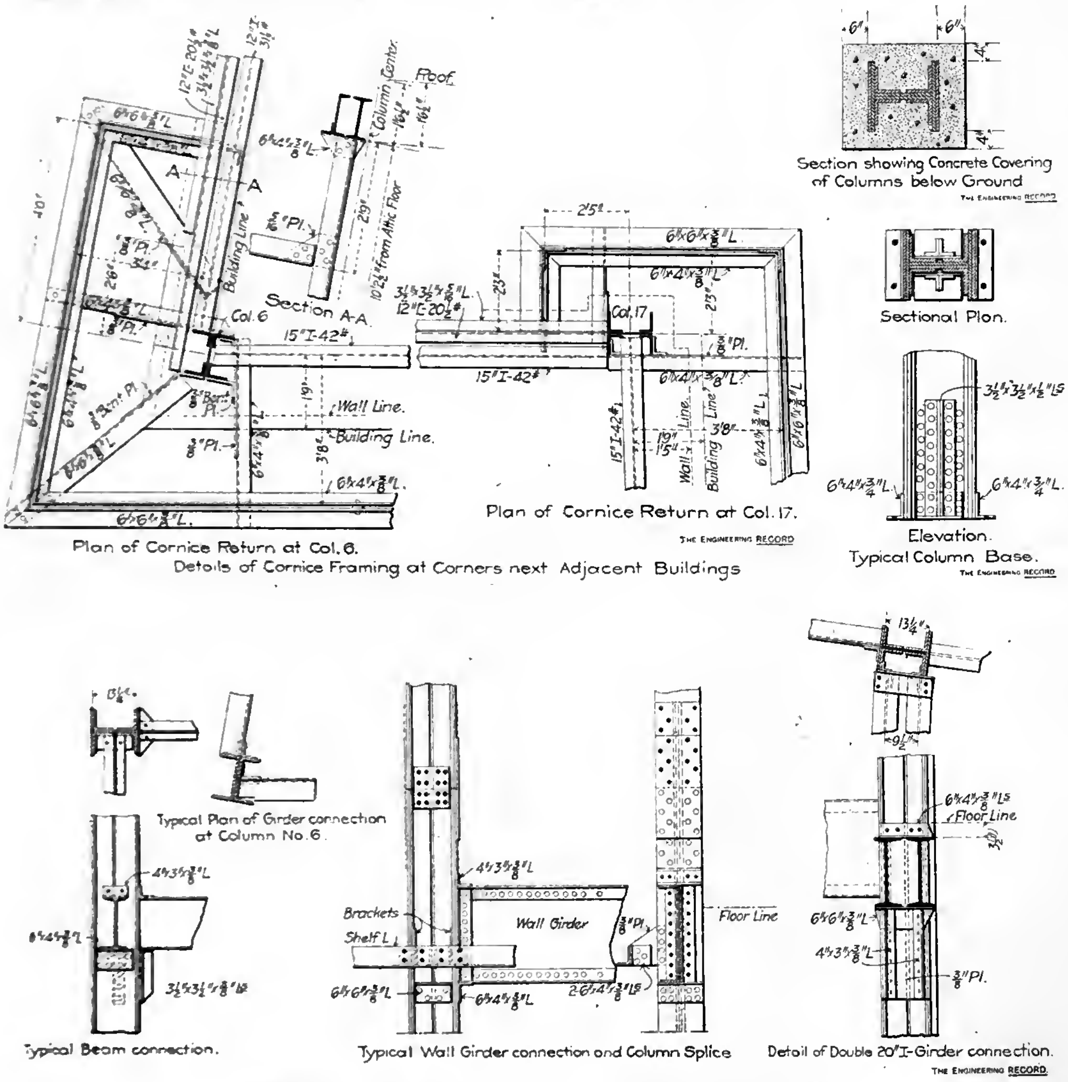




DETAILS OF THE SUPERSTRUCTURE OF THE HIBERNIA BUILDING, NEW ORLEANS.

chored to the wall girders as shown in the section of the street front spandrels. The heaviest courses are carried on a 10-inch channel bracketed out about 14 inches from the girder web, and the bottom courses and the window lintels are carried from a shelf angle which with the lintel angles is riveted to vertical frames suspended at intervals from the wall girders and the floorbeams.

At the 12th floor the wall columns are enclosed in masonry which projects from the face of the wall to form buttresses or pilasters. These are carried on shelf angles bracketed out from the wall girders and columns as shown in the horizontal sections through columns 6 and 14. At this floor the mullions and shelf angles on the Carondelet Street front are inside the wall girders and are suspended from their webs, and the terra cotta belt courses are carried on the lower flange angle which is reversed and about 4 inches above the lower edge that for the other floors in that there are no wall girders and that, as the excavation extends over only a part of the area of the lot, the floor rests on the earth beyond the basement walls and no part of it is carried by the wall columns. The outer ends of the floorbeams rest on cast iron bearing plates on top of the retaining walls and have pin anchors. Pipe trenches 4 feet wide, with concrete side walls, are carried from the retaining wall to the feet of the wall columns and are covered with 3x3-inch T-bars 18 inches apart resting on the side walls and supporting book tiles and concrete. The pavement is laid on the surface of the ground and its outer concrete edge is confined by a 6x4-inch curb angle with the horizontal lower flange turned inwards. The curb is anchored by transverse horizontal angles 2 feet long, riveted to it 5 feet apart, which are buried in the earth and have short transverse angles riveted across their inner ends.



DETAILS OF SUPERSTRUCTURE OF THE HIBERNIA BUILDING.

of the girder web. At the attic floor the terra cotta courses are carried partly on a 10-inch channel and 5x3½-inch angle bracketed out from the face of the wall girder, and partly from a 4x3-inch shelf angle suspended from brackets on the inside of the girder webs.

In the street fronts the wall girders carry on their top flanges vertical posts, about 6 feet apart, and 7 feet high, which are riveted at their upper ends to the horizontal 15-inch I-beams connecting the tops of the wall columns. These posts have T-shaped cross sections made with two 6x4-inch angles and have riveted between them at the top the solid web plates of brackets for projecting horizontal beams made of pairs of 6x4-inch angles 4 feet long carrying at their extremities two horizontal angles to support the overhanging cornice.

The first floor framing is very different from

At the street corners the cornice shelf angles project nearly 7 feet from the centers of the columns, on the diagonal line, and are mitered together and supported by special brackets riveted directly to the column flanges with oblique bent plates as shown in the plan at column 6.

The column details are very simple. All have I-shaped cross sections made with a web plate and four angles, and some of them have cover plates on the flange angles. At the foot of the lowest section of each column the web is reinforced by vertical angles and there are horizontal flange angles on every side to connect with the base plate seated on the planed top of a cast iron pedestal with extended base and longitudinal, transverse and diagonal webs. The column splices are made with web and flange cover plates, field-riveted to both sections. All plate girder connections have top and bottom shelf angles and vertical web connection angles. I-beam connections are made with top and bottom shelf angles, the latter reinforced by vertical angles when necessary.

The steel shell of the smokestack is 216½ feet high and is ⅜-inch thick in the bottom third of its height, 5 1/6 inch in the middle third and ¼ inch at the top. It is stiffened by inside horizontal rings of 2x1⅝-inch angles 3 feet apart vertically, and is made in 6-foot courses, shop-riveted together in sets of three with 4x5/16-inch outside splice plates. The 18-foot sections are field-riveted together with 2x3-inch flange angles. The smokestack passes through openings framed with longitudinal and transverse I-beams in every floor of the building, and at every third story each side of the shell is anchored by a projecting bracket with a vertical slot which engages a bolt in a lug riveted to the beam web and allows vertical adjustment for expansion and contraction.

The Sulphurous Anhydride Waste-Heat Engine.

Abstract of a paper read by Prof. Edward F. Miller, of the Massachusetts Institute of Technology, at the meeting of the New England Water-Works Association, November 12. The complete paper will be published in the forthcoming number of the "Journal" of the New England Water-Works Association.

For a few months back experiments have been made in Germany upon a new type of steam engine in which an unusually high efficiency is secured by increasing the range of temperature through which it works by reducing the temperature of exhaust far below what is current practice. The engine was described in the paper which, through Professor Miller's courtesy, we are enabled to abstract.

In an ordinary steam engine about sixty per cent. of the heat of the coal goes to waste, and the subject of the paper is how some of the heat that is lost can be recovered. The efficiency of any heat engine is evidently the ratio of the heat transformed into work to the heat received, or the heat supplied minus the heat exhausted divided by the heat supplied is the efficiency in per cent. It has been shown by theoretical discussion that for what is called the perfect engine, the efficiency is proportional to the ratio of the temperature worked through to the absolute temperature of the source of supply. As an illustration, take the case of the steam engine using steam at 165 pounds absolute pressure and exhausting at 26 inches vacuum, and see what would be the efficiency of the theoretically perfect engine. Such an engine is supposed to be one which has no losses, no cylinder condensation, no radiation, and the walls of the cylinder are supposed to absorb no heat. Such an engine is called the theoretically perfect or Carnot engine. Its efficiency would be the temperature of supply minus the temperature of exhaust divided by the absolute temperature of supply. Reducing the temperatures of the steam at the two pressures given to absolute zero, we get as the efficiency of the perfect steam engine 29 per cent. The actual engine, on account of its cylinder condensation and radiation, realizes only 80 per cent. of this and has a thermal efficiency of 23 per cent.

Attempts have been made recently to increase the efficiency by raising the temperature of the incoming steam. In modern plants in Germany it is now the custom to superheat the steam 300 degrees F. and that raises the efficiency. An engine working with the same pressures as those mentioned but with steam superheated 300 degrees F., gives us 48 per cent. as the efficiency for the perfect engine. Taking 80 per cent. of that we have about 38 per cent. as the efficiency of the actual engine, but, of course, if you superheat the steam it means that you must have an extra furnace or some superheating device, and that means that the cost of a pound of superheated steam is more than the cost of a pound of saturated steam.

It is only recently that attempts have been made to increase the efficiency by lowering the temperature of the exhaust. Evidently you can raise the efficiency by raising either the temperature of the source of supply or lowering the temperature of the exhaust. If you will consider the expression for efficiency for a moment you will see that for an engine to attain an efficiency of 100 per cent. the engine must transform all the heat it receives into work. It must exhaust no heat. It must exhaust at the absolute zero of temperature, or 460.7 degrees below zero Fahrenheit. One can see that the actual steam engine must necessarily have a limit to its efficiency. The best vacuum ordinarily maintained is about 26 inches. That means the temperature of the steam leaving is 126.3 degrees F. Cooling water for the condenser entering, say, at 70 degrees F. will leave the condenser somewhere in the vicinity of 130 degrees F. If you maintain a vacuum of 26 inches of course your cooling water will leave at a temperature much lower than 126.

Instead of using cooling water in the condenser the new engine uses sulphurous anhydride. Sulphurous anhydride at the ordinary temperature is a gas, colorless like air, has a peculiar odor of sulphur and can be easily liquefied at the ordinary temperature by applying a pressure of about twenty-five pounds. It is called SO_2 in chemistry, consisting one atom of sulphur and two of oxygen in a molecule. In the sulphurous anhydride engine the SO_2 is used in the place of the cooling water in a surface condenser. The sulphurous anhydride is vaporized and the SO_2 is used in a separate cylinder. This cylinder gives power which is utilized, and then the SO_2 from this separate cylinder passes to another condenser where it is condensed by cooling water, then the liquid SO_2 is again pumped back into the vaporizer or condenser, thus the SO_2 is used over and over again.

Figure 1 shows the arrangement of a triple expansion engine. The condenser in this case has to be made specially for the liquid sulphurous anhydride which passes in as indicated by the arrow. The steam is condensed and a vacuum is maintained on the low pressure cylinder by means of an ordinary air pump. The heat given up by the steam in condensing serves to vaporize the sulphurous anhydride, and the pressure of something like 175 pounds of the sulphurous anhydride vapor is maintained in this surface condenser. That vapor passes to the cylinder at the right where it is used, and from the cylinder at the right it exhausts to the condenser at the left, which is nothing but a surface condenser. After being condensed here under a pressure of forty pounds the liquid is pumped by a small pump back into the vaporizer, thus making a complete cycle. In Figure 2, the pressure curves of the SO_2 and steam are given. At 180 degrees F. the pressure of the steam is only 7.5 pounds, whereas the pressure of sulphurous anhydride is something like 270 pounds. At 100 degrees F. the pressure of sulphurous anhydride is something like 80 pounds, and its total heat is very much lower than that of steam. On the same cut, the total heat of a pound of steam ranges in the neighborhood of 1,100 and of sulphurous anhydride 190. This, of course, will make it evident that it is possible to vaporize sulphurous anhydride and get excessive pressures with it, the fact being that the total heat of sulphurous anhydride is low and its pressure rises rapidly with rising temperature.

Reproductions of indicator cards taken from the engine are given in Figure 3. The sulphurous anhydride card is shown at the bottom. The initial pressure in the cylinder was 160 pounds, the back pressure approximately 135 pounds. The size of the sulphurous anhydride

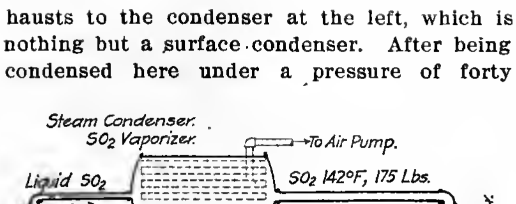

FIGURE 1.

cylinder was about the same as that of the high pressure cylinder.

On the combined diagram, Figure 4, the indicator cards from the sulphurous anhydride engine are plotted to the same scale as that of the steam cards. The shaded area is the low pressure card. Its length represents the volume of the cylinder and the height the actual

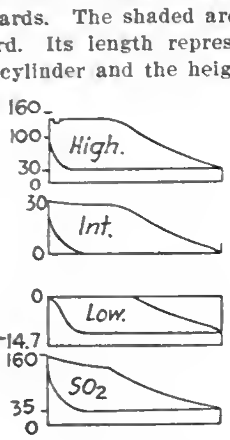

FIGURE 3.

pressure in it. The card above is the intermediate and the one above that the high pressure, each showing the range of temperature and pressure in a cylinder. Drawn to the same scale at the right is the sulphurous anhydride card shown on the diagram in Figure 3 and reduced to the same scale of volumes and scale of pressures. To make the comparison still more marked the card of the sulphurous anhydride cylinder is reduced to the same scale as the low pressure card.

The cards shown are taken from test number 8 given in the table. The table gives the date and results of a series of tests made by Professor E. Josse, of the Kgl. Tech. Hochschule of Berlin, Germany. The engine which he designed was about 175 horse power and the steam supplied to the engine was superheated some 200 degrees F. to 300 degrees F. in tests. The output in horse power obtained by the use of the SO_2 cylinder is between 30 and 40 of the total output of the steam engine. Theoretically this can be so, as will be seen by referring to the chart of efficiency. With the ordinary steam engine the range of temperature is from 365.9 degrees F. down to 126.3 degrees F. In the waste heat engine the temperature of the exhaust of the combined engine is reduced to 71 degrees F., which is the temperature of the SO_2 leaving the last cylinder. Suppose we substitute in the formula for efficiency. Instead of having 587 degrees F. as abso-

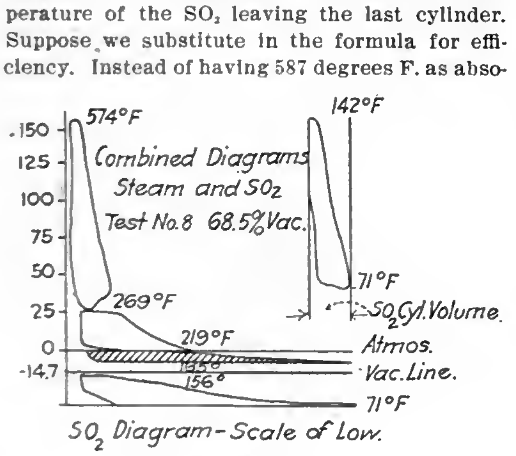

FIGURE 4.

lute temperature of the exhaust we have now 530.7 degrees F., giving us for the steam engine using saturated steam an efficiency of 36 per cent. as against 29 per cent. With the SO_2 cylinder attached to the steam engine cited in the second case where the steam was superheated 300 degrees, we obtain 53 per cent. efficiency against 48 per cent. The actual engine would probably realize 80 per cent. of these values.

The device for utilizing the waste heat can be attached to any engine which exists. The only thing needed is a safe, strong surface condenser to stand the pressure which you realize in the vaporizer acting as the condenser where the exhaust steam is condensed.

One might say that when combined with water SO_2 makes sulphurous acid, but there is no danger from any acid formed. As to the leakage and formation of H_2SO_3, the pressure of the SO_2 is always greater than the pressure against it, hence the tendency will be for the SO_2 to leak outwards, and should it leak outwards in the vaporizer it would immediately pass into the condensed steam which is constantly changing, so when the SO_2 combined with water it would pass off to the pump and be changing all the time. If it leaks into the other condenser where the pressure is 40 pounds, it would go into the cooling water, which is changing all the time.

Besides its application to the steam engine it can be applied in many other ways, as, for example, in the recovering of some of the waste heat of the exhaust of gas engines and in saving the heat of the flue gases leaving a battery of boilers. There is no reason why the draft cannot be maintained artificially and the heat going out from the exhaust be absorbed by an SO_2 vaporizer. The probable field for this engine and its most direct way into the market will be through its application to the gas engine. The ordinary gas engine gives a higher thermal efficiency than the steam engine, and the efficiency of the gas engine does not depend to any great extent on the load, as in the case of the steam engine. You often see the exhaust pipe of a gas engine of a dull cherry red color, which means a large loss of heat.

An SO_2 engine with vaporizer is now being applied to a gas engine in Germany. They intend to recover as much as possible of the waste heat of the gas engine by passing it through the SO_2 vaporizer. The steam engine of the class described has hardly passed the experimental stage. There have been three built which have been in use more than a year. There has been one running constantly day and night for about a year in an electric light station in Berlin furnishing power. The other engines have been built mostly for experimental work, and the earlier one was simply an old steam engine altered over to make it apply to this case.

The only difficulty so far has been in the method of packing the piston rod of the sulphurous anhydride cylinder. The difficulty was not a great one, but it was uncomfortable to work in the engine room if there was a leak of SO_2, and the stuffing boxes had to be absolutely tight in order to make it pleasant to visit that particular engine room. The difficulty was with the stuffing boxes, and the trouble has been overcome by making the stuffing box in two parts.

[A description of Prof. Josse's experimental engine and a brief account of the work done since 1892, the date when the subject was brought into prominence by the inventors Behrend & Zimmerman, was given in The Engineering Record of May 5, 1900.]

The American Institute of Architects will hold its thirty-sixth annual convention in Washington, D. C., December 11, 12 and 13. Papers on the "Improvement of Washington" will be presented by Messrs. Daniel H. Burnham, Frederic Law Olmsted, Jr., and Charles Moore, and Captain John Stephens Sewell, Engineer Corps, will read a paper on "The Relations of the Architect and the Engineer." The development of municipal improvement will be discussed by Messrs. W. B. de las Casas, Albert Kelsey, Owen Fleming and E. L. Masqueray.

The New York Tower Foundation for the Manhattan Bridge.

Bridge No. 3 across the East River will reach from the Bowery and Canal Street, Manhattan Borough, to Gold and Willoughby Streets, Borough of Brooklyn. It will be 9,330 feet long and 120 feet wide, and will have a main suspended span 1,400 feet long in the clear. Each tower for this span will have eight steel columns seated on a single masonry pier 23 feet above mean high water. The footings for these piers will be very large, wooden pneumatic caissons carried down beyond danger of settlement or scour. The Brooklyn pier and caisson, which is now nearly completed, were described and illustrated in The Engineering Record of March 2, 1901. Specifications have just been issued for the corresponding pier on the New York side, and notice of an invitation for bids for its construction appears in another column of this issue.

The 78x144-foot caisson will be 44½ feet in height and will correspond almost exactly to the Brooklyn caisson. According to the drawings and specifications, the masonry above the caisson is about four feet lower than that of the Brooklyn pier and differs from it chiefly in having only one well instead of three. It is built of 12x12-inch timber and 3x12-inch planks, with the walls of double, solid courses of timber and two courses of outside sheathing planks. The working chamber has a roof with two solid, crossed courses of timber and three of planks, and is divided into rectangular spaces by two longitudinal bulkheads and eight transverse struts. Above the roof there are transverse and longitudinal struts about 6 feet apart in alternate courses up to a height of 27½ feet above the cutting edge, and in every fourth course up to the top. These struts are braced together by diagonal timbers in longitudinal and transverse vertical planes, and all the interstices are filled solid with concrete to the top of the caisson, about 34 feet below mean high water.

Above that point there is a removable cofferdam, 44 feet high, constructed similarly to the caisson walls in three detachable vertical sections and having longitudinal and transverse struts 12 feet apart in horizontal planes about 6 feet apart. These struts are X-braced in vertical planes by planks which are removed when the masonry is built. The cutting edge and vertical corners are shod with steel angle plates, and the seams are calked with two threads of cotton, followed with four threads of oakum and served with hot pitch. The concrete is made with Portland cement and is machine mixed. The nine preliminary diamond drill borings indicate water of a maximum depth of from 25 to 46 feet, then silt, sand and gravel to a bed of rock or boulders at a depth varying from 100 to 129 feet below mean high tide. It is expected that the caisson will be sunk to a depth of about 79 feet and seated on fine sand and gravel. It is required that the work shall be completed in 300 consecutive working days, and that the bids shall be for a total price for completed work down to —79.15 feet, and for additional prices per cubic yard for work between horizontal planes at —79.15, —83, —87, —91, —95, —99 and —103 feet below mean high water.

The caisson is to be completed, before launching, to a height of 27½ feet, and will then contain 95,450 cubic feet of timber and 148 tons of iron, will weigh about 2,534 tons and will draw, without false bottom, about 13 feet. While floating it will be completed to a height of 44 feet 9½ inches and will then contain 128,100 cubic feet of timber, 163 tons of iron, will weigh 3,888 tons and will draw 15 feet. The bottom will be dredged from about 33 to 40 feet and to land the caisson on it about 5,300 cubic yards of concrete will be deposited in the caisson. To sink the caisson to —79.15 it will require to be filled with concrete up to the footing course and to be loaded with about 761 cubic feet of ashlar stone masonry besides. The approximate estimated total quantities are as follows: Dredging, 3,530 yards; excavation in caisson, 16,300 yards; timber in caisson, 132,000 cubic feet; iron in caisson, exclusive of pipes and shafts, 163 tons; concrete above roof, 12,500 yards; concrete below roof, 2,511 yards; masonry in pier, limestone 13,740 yards, granite 2,690 yards; timber in cofferdam, 45,522 cubic feet; iron in cofferdam, 41.2 tons.

The specifications contain some special provisions, among which it is required that the contractor must keep a fire extinguishing apparatus in proximity to the caisson at all stages of the work. The air shafts for men shall not be less than 4½ feet inside diameter, and must be equipped with elevators, and every safeguard must be taken to protect the men from the injurious effects of working under pressure. Electric lights and a telephone must be provided in the working chamber. Special care must be taken in concreting in the working chamber under the cutting edge, under the bulkheads and under cross timbers where there shall be in all cases a thickness of 6 inches of concrete for the full width. Pneumatic rammers must be used for the concrete in sealing the working chamber and in difficult places, and where ramming is impracticable the spaces must be grouted under pressure.

The work is being executed under direction of Mr. Gustav Lindenthal, Commissioner of the Department of Bridges, and Mr. H. A. LaChicotte, engineer in charge.

A Break in a Cast-Iron Pipe in the Thirlmere aqueduct supplying water to Manchester, England, emphasizes once again the importance of attention to a detail of pipe laying with which all water-works men should be familiar, especially inspectors and foremen, to whom it usually falls to see that the conditions of the pipe as placed in the trench are right. The following account of the accident is taken from "Engineering:"

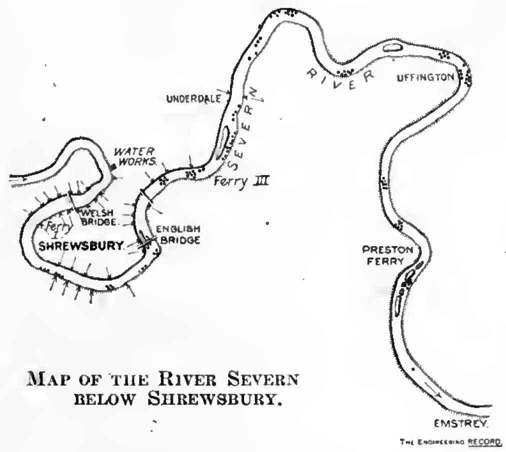
The week before last, the whole side of a pipe in the Thirlmere aqueduct burst out in one piece under the pressure of the water. The cause of the accident is remarkable. A second line of pipe is being laid. The pipe which gave way on the old line was just one length ahead of the last length laid in the new line, and the excavation had been made to receive the new pipe opposite to it. This excavation was about 10 feet deep, and was properly timbered. The men had ceased work a quarter of an hour before the burst occurred. When the outrush of water had been checked by the automatic valves on the line of pipe, it was found that the whole weight of the water and of the pipe, which was laid on the slope of a hill, was unsupported, except by a pinnacle of rock which jutted up under its center. The rest of the bed must have been soft ground. A photograph, which shows this rock and the fractured pipe, was taken just after the excavation above the pipe had been made for its removal, but before the ground below had been disturbed after the rush of water. There was a small transverse crack visible just above the point of contact between the pipe and rock. The diameter of the pipe was 40 inches; length, 12 feet; and the thickness of the metal, which was good cast-iron, was 1⅜ inches. The head of water in the pipe was 270 feet. The joints were bell and spigot.

Pollution and Self Purification of the River Severn at Shrewsbury.

A Review by George C. Whipple.

The second report of the Royal Commission on Sewage Disposal, recently issued, contained an interesting study of the pollution and self purification of the River Severn at Shrewsbury, by Prof. Boyce and Drs. MacConkey, Grünbaum and Hill. Shrewsbury is a town of about 29,000 inhabitants, located on a bend in the River Severn at a point where the minimum flow is about 85,000,000 gallons per day and the maximum flow something above 1,000,000,000 gallons. From this stream the town takes its water supply without filtration (the water is not used for drinking, however), and into this stream all its sewage is discharged without treatment. The dry sewage flow is said to be about 844,000 gallons per day, equal to about 1 per cent. of the volume of the stream. The upper reaches of the River Severn are comparatively unpolluted. One of its most important tributaries is the River Vyrnwy, which is one of the main sources of the water supply of Liverpool. This part of the watershed is scrupulously protected from contamination.

The water supply of Shrewsbury is drawn from a point in the stream just above the town, and above the intake the only important source of pollution is the sewage from the County Asylum, which enters the river two miles above. As the river winds through the town it receives from both banks the discharges of 36 small sewers, which enter at the points indicated on the accompanying map. In addition to this it receives deposits of garbage, refuse of all kinds, ashes, and the wastes from several manufacturing establishments. Below Underdale the amount of pollution is small, and except for occasional "land drains" there is but little pollution down to Ironbridge, the next town on the river below Shrewsbury, a distance of 23.5 miles. The water in the "soil drains" was, with one exception, perfectly clear, and out of 17 drains which were tested for the presence of B. Coli, 70 per cent. of them gave negative results, while the numbers of bacteria varied between 100 and 3,000 per cubic centimeter. Of 17 tributary brooks which were examined all were found to contain B. Coli in small numbers. The object of the investigations was to ascertain the character of the water at various points between the County Asylum and Ironbridge, and the effect of the sewage upon the bottom and shores of the stream. Two lines of work were carried on: first, that of the analysis of water at various places, and second, that of a study of the stream deposits. In both of these prominence was given to bacteriological rather than to chemical data.



MAP OF THE RIVER SEVERN BELOW SHREWSBURY.

Water Analyses: The water in the River Severn above the County Asylum was said to show but slight traces of pollution, but at the point from which the water supply of the town was drawn the evidences of pollution were quite marked, as may be seen from the following range of analyses:

Analysis of Water of the River Severn at the Intake of the Shrewsbury Water Works. Range from November 18, 1899, to March 27, 1901.

	—Parts per Million.—		
Total solids	112.8	to	162.4
Chlorine	9.7	"	20.0
Oxygen consumed in 4 hours	1.2	"	3.4
Nitrogen as albuminoid ammonia	.071	"	.125
Nitrogen as free ammonia	.028	"	.102
Nitrogen as nitrates	.30	"	.40
Number of bacteria per cubic centimeter	430	to	64,500
Number of B. Coli per cubic centimeter	1	"	111
Per cent. of samples which contained B. Enteritidis sporogenes	27		

Color, dark brown.

The number of bacteria varied, according to the stage of the river, from 430 to 64,000 per cubic centimeter, while every sample was found to contain B. Coli in numbers which ranged from 1 to 111 per cubic centimeter. The turbidity of the river water varied according to the rainfall but the method used for measuring the turbidity was an arbitrary one, based on the use of the centrifugal machine, and there appears to be no way by which their results can be transferred into terms with which American analysts are familiar. The water when clear is said to have a dark brown color, due to peaty matter in solution.

Samples collected from the stream as it flows through the town show the effect of pollution in the increased turbidity, the amount of organic matter, the total number of bacteria and the number of B. Coli per cubic centimeter. Below the town the water improves in character until at Cressage, 18 miles down stream, the total number of bacteria is lower than at the County Asylum. The numbers of B. Coli, however, do not decrease so rapidly, as will be seen from the figures in the following table. This may be due to the effect of the small feeders which, as above stated, were not entirely free of B. Coli.

Average Analyses of the Water in the River Severn at Various Points between Asylum and Ironbridge. November 18, 1899, to March 27, 1901.

Miles.	Locality.	Parts per Million. Albuminoid ammonia.	Free ammonia.	Nitrates.	Number of bacteria per c.c.	Number of B. Coli per c.c.	Per cent. of samples which contained B. enteritidis sporogenes.	*Turbidity.
0.0	Asylum	.090	.009	.42	7,000	13	0.0	5.5
2.0	Water works	.113	.056	.43	13,000	46	27.0	..
2.6	Ferry I.	...	...	..	20,000	177	51.2	..
3.6	English Bridge	...	...	..	23,000	321	85.7	..
4.5	Ferry III.	.197	.073	.42	19,000	600	41.7	8
6.75	Uffington	.153	.062	.57	17,000	142	33.3	7
11.0	Atcham	.135	.048	.51	13,000	48	38.9	6.9
18.0	Cressage	.147	.044	.43	5,000	36	31.6	6.8

*Parts of suspended matter in 600 cubic centimeters water.

The authors place great stress on the test for B. Coli as an indication of the sanitary condition of the water, but from the description of the methods which they employed, it is questionable whether they have not included under the term B. Coli certain related forms which are not of intestinal origin. In fact they admit this, and give a list of bacteria which they consider as belonging to the general group of B. Coli. Their contention that all these organisms are in a measure indicative of contamination seems to be sound, judging from their experiments and from the work of other investigators in the same line. Their tests for the presence of B. enteritidis sporogenes, for example, follow along in parallel series with the tests of B. Coli, as shown by the table.

The authors attribute the improvement in the quality of the water below the town to dilution, sedimentation, the straining action of aquatic plants, and the influence of some of the lower forms of microscopic life. In order to compare the purification which takes place in the River Severn with that of other rivers, they give a table of the results of certain German investigators, and show that there is a general correspondence between them. Thus, experiments made in 1890 by the Imperial Board of Health of Berlin gave the following number of bacteria in the water above and below the city:

Locality.	Number of Bacteria per c.c.
Above Berlin	8,900
Just below Berlin	24,400
2.8 miles below Berlin	34,300
6.7 miles below Berlin	170,000
8.7 miles below Berlin	131,000
10.3 miles below Berlin	17,500
43.5 miles below Berlin	9,200

This river, which has a normal flow of about 25,000,000 gallons per day, is said to receive 1/30 of its volume of sewage.

Stream Deposits.—The River Severn at Shrewsbury has an average width of about 200 feet, and is comparatively shallow above and below the town. Its bottom is gravelly and rocky, but between the water-works and Ferry III. it is filled with irregular deposits of mud. The banks of the stream are for the most part muddy and lined with willow trees. During the summer season there is an extensive growth of weeds, such as the water Ranunculus, Potamogeton and Myriophynlum, which in places extend from shore to shore across the stream. These water weeds exert a marked influence on the deposition of suspended matter in the stream.

In order to determine at what points in the stream the more solid portions of the polluting material tend to settle, the experiment was made of putting into the stream at Ferry I. a large number of colored corks. After 15 hours the river was examined and the position of the corks noted. They were found in the positions shown on the map. It was observed that for the most part they had lodged over heavy deposits of mud, and it was noted that the color of the mud in these places was blacker than elsewhere in the stream, and was more offensive in character. Samples of mud were collected for analysis at various points between the County Asylum and Ironbridge, and were found to contain the following numbers of B. Coli:

Locality.	Number of B. Coli per gram.		
Above County Asylum	8	to	70
Between County Asylum and the Water Works	30	"	1,600
Between Water Works and English Bridge	49,000	"	52,000
Opposite Brewery sewer above English Bridge	300,000	"	1,200,000
Between English Bridge and Ferry III	2,240	"	43,200
Between Ferry III. and Uffington	1,580	"	17,500
Between Uffington and Cressage	33	"	2,490
Between Cressage and Ironbridge	33	"	165

On the map, the sewer outlets are shown by the arrows; and the positions, on May 17, 1900, of the corks thrown in at Ferry I. on the preceding day are indicated by dots in the river.

These results show that the mud of the stream was seriously contaminated all the way from Shrewsbury to Ironbridge, and indicate how at times of flood these deposits may become secondary sources of pollution. In some cases it was found that decomposition was taking place under anaerobic conditions, and the authors pointed out how the gaseous products might create nuisances along the stream. The authors claim that they have found no evidences of the multiplication of B. Coli in the water of the river.

The article is illustrated with 4 maps, 5 diagrams and several excellent photographs of micro-organisms, besides 20 tables which give in detail the results of analyses.

Experimental Laboratory of the North German Lloyd.

In a recent issue of the "Austrian Weekly of Public Works" Herr A. Schromm gives a description of the experimental station of the North German Lloyd, at Bremerhaven, which is of considerable interest. A condensed translation of this paper is given below:

The object of such an experimental laboratory for shipbuilding is to furnish data based on the resistance encountered by the model of a ship, if moved through a water tank with a certain velocity. These data are to be used to determine the resistance of ships of forms similar to those experimented upon. The experiments made in this direction by the well known English naval engineer, Mr. Froude, have been fundamental in this direction. Mr. Froude was the first to base on such experiments with models a theory of ship resistance, and his theory remains the best in the field, giving results nearest to the actual facts.

According to the character of the ship to be built its displacement is computed and its water-lines are laid out. From this plan the model of the ship is made, in this laboratory, by means of an ingenious machine which cuts the model out of paraffine. These paraffine models are generally 13 to 16 feet long and are perfectly similar to the geometric shape of the intended ship. The model is drawn through a tank filled with water and its resistance to motion is measured by a dynamometer, which records automatically the time and the space traversed. The extreme difficulty of designing an absolutely correct ship is seen at once from the consideration that, for a given displacement, an indefinite number of dimensions are possible in length, width and draft. Of course conditions set by harbors or rivers, canals or docks, limit the variations to a considerable extent, nevertheless, numerous forms of ships are still left which all satisfy a given displacement. A model tank therefore furnishes sure means for determining which forms will best satisfy the required conditions. Before the introduction of this experimental method, the design of the form of boats consisted merely in copying previous successful boats. For centuries this was the only procedure, and the ship-builder kept the secret of a successful ship hidden from the rest of the world.

The tank of the Lloyd's laboratory is some 540 feet long and 20 feet wide, and has a depth of 10.5 feet. Along the sides a substantial track is laid on which the traction platform, 20.5 by 31 feet, is moved by electric motors. The motive power is so controlled that it can furnish 430 different but uniform velocities varying from 1.5 to 15.5 feet per second. The corresponding velocity of the model is computed according to the principle of the "mechanical similarity," announced by Newton. Froude was the first to apply this Newtonian principle to the computation of the velocities of his models. The principle of the "mechanical similarity" is: If two ships exactly similar geometrically move in water with corresponding velocities, the wave and vortex resistances of these bodies are to each other as the third power of their linear dimensions or as their displacements.

The required corresponding velocity having been determined the model is tested for a range of velocities both sides of the computed value. The different velocities of traction and their corresponding resistances are then plotted as abscisses and ordinates respectively and the curve of resistance is thus obtained. The total resistance, W, encountered by a body moving in water may be divided into two parts, a resistance due to friction, W_1, and a resistance due to wave and vortex motion, W_2. The first is caused by the friction of the wetted surface of the floating body on the water, the second by the formation of waves in front of the body and the wave and vortex formation in its back. According to Froude's formula the friction resistance is determined empirically. It is a direct function of the area and character of the wetted surface, of the density of the water and of the velocity at which the model is moved through the water. If the co-efficients of friction for the different kinds of surface of the model and of the ship are known, the frictional resistances can be computed without further difficulty. If the total resistance of the model has been determined by experiment, the wave and vortex resistance, which cannot be computed, is found by the subtraction of the frictional from the total resistance.

The wave and vortex resistance of the model once having been determined by experiments it needs only to be multiplied by a^3, that is by the third power of the ratio of the scale of the ship to the model in order to find the corresponding resistance of the ship. Adding to the latter resistance the frictional resistance, the total resistance of the ship is given by:

$$W = W_2 a^3 + W_1$$

The paraffine used for making the models has a specific gravity of 0.87 and a melting point of 58° to 63° C. The moulding box is some 20 feet long, 3.3 feet wide and 3 feet deep. The model consists of a hollow casting about 1½ to 1¾ inches thick. It is cut to the required shape and dimensions by a rotary model cutting machine which is ingeniously arranged to follow the lines on the drawing.

Gas Power Development.

Some interesting installations of gas generators in connection with gas engine central stations for producing electricity for light and power are under course of construction by Westinghouse, Church, Kerr & Company, engineers, New York City. At the Winchester Repeating Arms Company, in New Haven, a power house has been designed to accommodate a new gas engine equipment and the entire power for manufacturing and lighting purposes will be supplied from it. Three Westinghouse gas engines aggregating 500 horse-power drive direct-current generators, two additional units to be employed as auxiliaries and Loomis Pettibone gas generators comprise this plant.

The gas making plant of the Consolidated Industries Company, at Batavia, N. Y., will be arranged to produce metallurgical coke and fuel gas, the latter to operate gas engines driving alternating-current generators. At Rockland, N. Y., there will be an installation consisting of an independent gas manufacturing plant employing the Loomis Pettibone process, and a power plant containing Westinghouse direct-connected gas engine generator units. The producer plant will supply water gas to the Ramapo Iron Works and the Ramapo Foundry Company for heating and metallurgical purposes, and electric power to other industrial plants in the vicinity, including the Standard Brake Shoe Company, located about 4 miles distant from Hillburn. The plant will also supply current for lighting throughout the Ramapo Valley district, some 14 miles in extent. The gas engines installed are also of the new Westinghouse horizontal double-acting type of 350 horse-power, each equipment aggregating 1,200 brake horse-power or 1,400 brake horse-power maximum. The engines are direct connected to Westinghouse polyphase generators and constructed to operate in parallel. A 128 horse-power vertical gas engine unit will also be employed for carrying light loads, and assisting at peak loads.

The Artesian Water Supply of Memphis, Tenn.

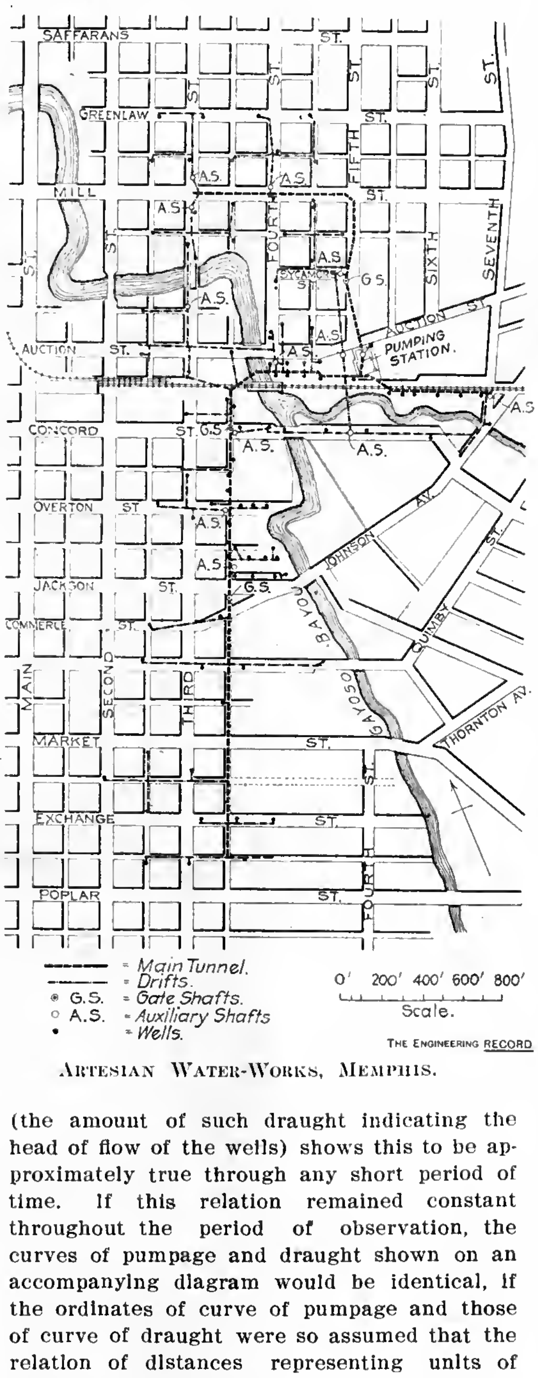
The present supply for the Memphis waterworks system is derived from a stratum of water-bearing sand underlying the Mississippi valley in that neighborhood, about 350 feet below the surface. The water is obtained by means of wells 6, 8, and 10 inches in diameter sunk through the upper stratum of impervious clay and extending well into the sand. Brass strainers about 50 feet long are attached to the bottoms of the well casings, to collect the water and prevent the influx of sand. The older wells generally had single casings of 6 or 8-inch wrought iron pipe, while the later casings are of heavier, 10-inch steel pipe, with specially protected threads, and an outer, or protective, casing of 13-inch steel pipe.

The water is found to be under pressure not quite sufficient to cause it to flow from the tops of the wells at the surface of the ground, although it has been stated that originally it rose 6 or 7 feet above the surface. On this account a tunnel with drifts connecting with the individual wells was constructed at a depth of 70 or 75 feet below the surface. Through these drifts and the tunnel the water is led to a suction chamber, from which it is lifted by the pumps and then forced through the distributing mains to the various parts of the city. In the different shafts, shown on the plan of the supply system, are gates operated from the surface, by means of which a section of the supply system can be shut off from the remainder, its wells balled off (i.e., shut off from the tunnel) from the surface, the water pumped out from the pump chamber in the shaft, and the section made accessible for inspection or repairs. An extended description of these works soon after their construction was given in The Engineering Record of September 12, December 5 and 19, 1891, January 2 and February 13 and 20, 1892.

The city of Memphis is growing rapidly, and it is estimated that in a short time there will be a demand for 20,000,000 to 30,000,000 gallons per day made on its water supply. It has also been estimated that the economical limit of supply from the present system of wells, taken at 25,000,000 gallons per day, will be reached in five years, at the outside. It is therefore evident that a very considerable increase in the supply will be necessary within a few years, and the question arose as to whether the system of artesian wells could be profitably extended so as to practically double the supply, or whether it would be better to take the additional supply from the Mississippi River. Three consulting engineers, Messrs. Arthur Hider, J. A. Omberg, Jr., and A. T. Bell, were engaged by the city to investigate this matter, and report, among other things, on the condition and value of the present plant, which is owned by the Artesian Water Company, of Memphis. Some valuable information in regard to the action of artesian wells was obtained by this commission in the course of their investigations, which is presented in a special report. This report, together with one on the financial condition of the Artesian Water Company by Messrs. Haskins & Sells, public accountants, of New York, was presented to the city council of Memphis recently and, somewhat condensed and rearranged, form the major part of this article.

There is a definite limit to the rate at which water can be obtained from any well or system of wells. The quantity which will flow from any one well will depend on three factors, the pressure at which it discharges, the size of the pipe, and the freedom with which the water enters the well at the strainer. In the case of a number of wells, the aggregate discharge is governed by the same conditions. Observations of the total discharge from the Memphis wells under very different conditions extending over the period of four years considered by the commission, show plainly the effect of varying any of the three factors just named.

Experimentation on individual wells has shown that the quantity of water discharged from a given well varies directly with the head of flow; that is, if a well flowing under a given head yield a given quantity of water per second, at twice the given head the quantity of flow will be approximately doubled. If this be true for each individual well, the total yield from a system of a fixed number of wells should bear a fixed relation to the draught or head of discharge. A comparison of the rate of pumping and the corresponding draught or lowering of the level in the suction chamber



ARTESIAN WATER-WORKS, MEMPHIS.

(the amount of such draught indicating the head of flow of the wells) shows this to be approximately true through any short period of time. If this relation remained constant throughout the period of observation, the curves of pumpage and draught shown on an accompanying diagram would be identical, if the ordinates of curve of pumpage and those of curve of draught were so assumed that the relation of distances representing units of pumpage and units of draught were the same as the constant relation between pumpage and draught. For example, if it were found that for every 4 feet of draught there were about 1,000,000 gallons of water per day discharged, then the spaces on pumpage curve representing 1,000,000 gallons should be equal to those on draught curve representing 4 feet of draught.

This relation of 4 feet of draught per million gallons per day was found to be close to the true relation between pumpage and draught, and the curves on the diagram were plotted on that basis. A glance at the diagram, however, shows that the curve of draught, while showing variations corresponding to change in pumpage, is far from being identical with it. This variation in the relation between the flow and head is evidently due to the other two conditions determining flow, viz., size of wells and the freedom with which the water enters the strainer. By size of wells is meant the aggregate sectional area, or the number of wells. The number of wells in use since 1897 has been nearly constant, so that the amount of discrepancies between the two curves represents approximately the comparative freedom with which water entered the strainers. In the other part of the same diagram the amount of variation in the relation between flow and head is shown and the curve represents the relative condition of the supply at various times. With a given condition of supply represented by a point on the curve, it is easy to determine approximately the maximum probable yield from the system of wells in use at that time, at suction limit or maximum draught.

In October, 1898, the condition of the supply system was at its worst, showing that at that time, with that system of wells, the maximum rate of yield possible was only about 10,200,000 gallons per day, a rate which would be totally inadequate to supply the present demand. This condition was due to the abandonment of an old battery of wells shortly before. The very marked improvement in the next six months showing the ultimate rate of yield at suction limit to have increased to about 19,000,000 gallons per day, was due to turning on thirteen new wells. The same marked improvement is shown where nineteen new wells were turned on in January, 1901, though the improvement due to the nineteen new wells is not proportionately greater than that due to the thirteen wells, because of the greater average quantity pumped reducing the general head of flow from the system.

In this connection it will be noted from the diagram that the increase in the rate of yield due to increasing the number of wells is not entirely permanent, but gradually falls away, and in the course of a year or two, almost disappears. This is due to the deterioration in the condition of the individual wells. Tests of the flow from the individual wells show that the discharge is always much greater shortly after first being turned on than after it has been in use for a time. This rapid reduction of the average flow is to be expected, is unavoidable, and does not in any way represent a depreciation of the well. It is due to the voids in the average coarse sand around the strainer becoming more or less filled by finer sand from the surrounding area, which is carried by the water flowing toward the well.

An average condition of a supply of about 50 wells for the past four years shows a rate of yield of about 14,900,000 gallons per day at suction limit. By cleaning strainers and sinking more wells this maximum may be brought up greatly. The curve of condition shows that on July 1, 1902, this limit of supply was about 17,500,000 gallons, and had been raised to that amount since April, when it was about 16,500,000 by flushing strainers. On July 18, six new wells were connected and increased the total flow to about 19,000,000 gallons per day, from which it may recede during the next four months to about 17,500,000 gallons per day. The ultimate rate of yield referred to does not mean the ultimate rate obtainable from the artesian sands at that point, but the maximum rate of yield from the systems of wells, under existing conditions, already in use at the time of observation. By the condition of the wells generally, is meant the condition of the material immediately around the strainer. If there is a small stratum of clay in proximity to the strainer, the slots quickly become clogged and the well flow is diminished accordingly. If there are indications of clay in proximity to the strainer, shown by whitish or milky water, it would probably be better to abandon the well and draw the casing for utilization elsewhere.

When a well made in good sand shows considerable decrease in flow, flushing is resorted to, to improve its condition. In doing this a stream of water under considerable pressure is forced from the inside of the strainer through the slots and into the sand. An ingenious tool has been devised for this purpose, which confines the water to a small section of the strainer, insuring a much more thorough cleansing than is possible by merely forcing a stream of water down the well and allowing it to dissipate through the parts of the strainer offering the least resistance. A diagram in the report of the commission (not reproduced) gives some of the results of flushing with this tool. An average of four wells shows a falling off in flow of about 32 per cent. during nine months, after which flushing was begun and increased the flow about 70 per cent., or about 13 per cent. above the original condition at the beginning of the record. The average of two other wells which were not flushed showed a very regular decrease in flow from 230,000 to 120,000 gallons in seven months.

The flushing tool mentioned has been in use only since April, 1902, hence no extended period of observation is available, but the results thus far seem to show that the present supply system can be increased about 20 per cent. by its use. The effect of this flushing seems to disappear in about three to five months. The expense of each flushing is at present about $70, making a maintenance charge of about $23 per month per well, on a basis of flushing four times a year in order to maintain 19,000,000 or 20,000,000-gallon supply. In order to obtain and maintain a supply greater than this, or to obtain an absolutely reliable supply of this size, it will be necessary to materially increase the number of wells.

If each additional well sunk increased the supply in proportion to the number of wells, there would be no limit to the supply obtainable by adding to the number of the wells; but such is not the case. Each new well sunk diminishes the flow from the existing wells, and provides an additional quantity of water equal only to the difference between its own flow and the diminution of the aggregate flow of the other wells, caused by reducing the head. As the number of wells in a given area increases, the difference between these two quantities becomes smaller and smaller until a point is reached where the revenue from the increased amount of water would not justify the interest and maintenance charges on the well and additional underground construction.

In this connection it is interesting to note what occurred when engineering operations were first begun on the system with a temporary plant in May, 1888. At that time, wells 21 to 31 inclusive were connected at the surface of the ground by a cast iron suction pipe. On May 10, a test was made as follows: First, by means of gates all the wells were disconnected from the pipe but one. Before starting the pump, the water rose in the well pipe some 6 or 7 feet above the surface of the ground. The pump, which was depressed several feet below the surface of the ground, was then started and the water in the well was lowered about 30 feet, or as low as the pump could draw it and surely fill the pump chambers. The quantity pumped was at the rate of a little over 1,000,000 gallons per day. One after another of the wells were added, until eight wells were in operation, the water in them being lowered as before about 30 feet below the flow line. The result was a total yield at the rate of 2,500,000 gallons per day from the eight wells.

The present area over which wells are distributed is about one quarter of a square mile. The absolute maximum amount possible from that area would be obtained when the whole area was converted into one vast well of one

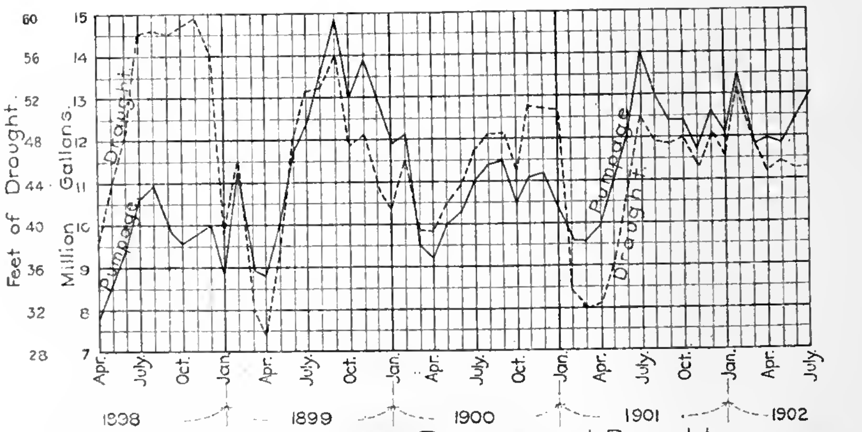
Variation in Condition of Supply and Ultimate Yield of Supply at Suction Limit.



Relation between Pumpage and Draught.

DIAGRAMS SHOWING CONDITION OF SUPPLY.

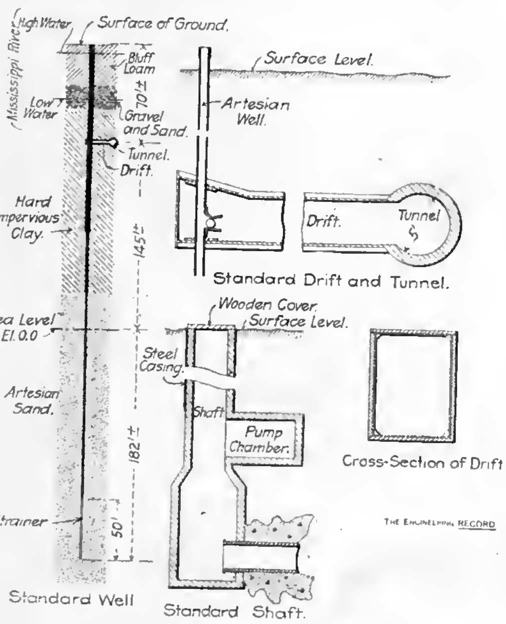
quarter of a square mile sectional area. The quantity of water which could be obtained from such a well can be determined if it be assumed that the quantity of discharge will vary directly as the draught, an assumption known to be erring on the safe side through the commission's range of observation. Data for this estimate were obtained from an observation of the depth of draught in wells bailed off (i.e., tunnel connection closed and water allowed to reach its static level), in close proximity to the area of supply, at various depths of draught in pump well. At a draught of 35 feet in pump well the draught in the bailed off well was 21 feet; at pump well draught of 50 feet the draught in well was about 29 feet, showing a difference of about eight feet of draught in level to 15 feet difference in draught in area of supply. The pump well draughts of 35 and 50 feet represent respectively about 8,750,000 and 15,000,000 gallons per day, or a difference of about 6,250,000 gallons per day which causes the 8-foot increase in draught of static level in areas contiguous to supply area. At maximum supply obtainable, this static level would be reduced to level of supply area, or about 60 feet. In order to do this, a supply of about 800,000 gallons per foot of decrease would have to be disposed of. This indicates an ultimate supply close to 50,000,000 gallons per day as the absolute maximum from a limited area. The economical limit of quantity from a given area, beyond which it would be impracticable to go, is probably in the neighborhood of 25,000,000 to 30,000,000 gallons per day. In providing a supply in excess of the economical limit of the present system, it is well to anticipate the demand by 20 years or more, or to provide for a total supply of 50,000,000 to 60,000,000 gallons per day. This would require an entirely independent system, in many respects a duplication of the present one.

A diagram is given showing the hydraulic surface in the neighborhood of the wells, and also the probable effect of a second similar system located about four miles away. From the diagram it is seen that at a distance of about four miles from the present station, the effect of the draught is very little more than it would be several miles further away, indicating that it might be safe to establish a new supply at this distance from the present station, both stations to yield about 15,000,000 gallons per day. The effect on the slope of the increase in the quantity pumped is plainly indicated by the diagram, which shows the difference in the hydraulic slope in 1898, when about 9,000,000 gallons per day were pumped, and in 1902, when the daily average is about 12,000,000 gallons.

The probable cost of an independent system is given as follows:

50 10-inch wells at $3,000	$150,000
10,000 feet drifts at $8	80,000
5,000 feet 5-foot tunnel at $18	90,000
Shafts, auxiliaries, gates, etc.	45,000
Pump pit, etc.	40,000
Building and stacks	55,000
Boilers, pumps, machinery, etc.	215,000
Additional main, 10,000 feet at $10	100,000
Engineering and contingencies	116,250
Total	$891,250

The chief expense of an artesian system, outside of interest and ordinary operating expenses, which are assumed in this case to be about equal for all systems, is in the maintenance and depreciation of the wells. This item in recent experience amounts to about $20 per month per well for maintenance, and, allowing $17 per month for depreciation, the total expense is about $4 per million gallons,



Details of Well and Connections.

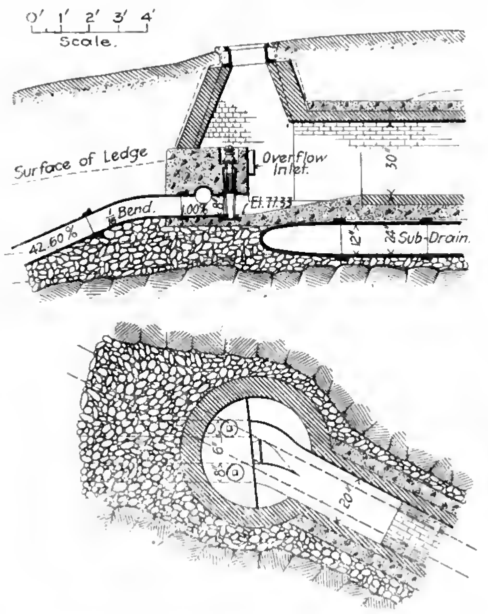
on a basis of 300,000 gallons per day per well. Comparing this with the corresponding extra expense of the slow filtration of the Mississippi River water, a conservative estimate shows a difference in cost in favor of the artesian supply of about $1 per million gallons. Disregarding this small difference in cost, in the event of the city acquiring the present plant, on account of the indicated ample supply of artesian water, its known purity and healthfulness, and the feasibility of obtaining it, the commission of engineers recommended its continued use, by enlarging the present plant and supply, and later on when the needs of the city require it, the construction of an independent station, located at least four miles from the present station.

Erratum. In the article on the Rio Grande Bridge, published November 8, corrections should be made as follows at the top of the first column on page 434. The three lines just below the formula should read: H = total horizontal thrust; S_0 = total stress in a member from horizontal unit reaction only; S_1 = total stress in a member from vertical unit reaction only.

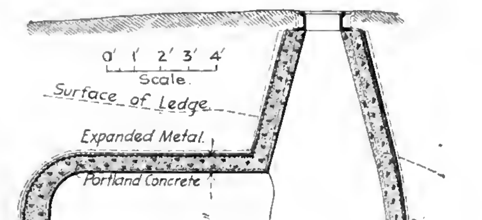
Difficult Sewer Construction at Newton, Mass.

In the extension of the main sewer through Hemlock Gorge, for the Newton Upper Falls district, many obstacles had to be overcome, the physical features of this section presenting many difficulties which made the work slow and expensive. Ledge and water were encountered throughout the whole distance of about 1,750 feet. The work was briefly described in the last annual report of the city engineer of Newton, Mr. Irving T. Farnham, from which report the following account has been prepared:

From the point in Boylston Street where the trunk sewer built in 1900 ended, the extension passes through a rock tunnel 193 feet long as a 20x30-inch egg-shaped sewer; then follows along the bed of the Charles River as a 20-inch cast-iron pipe to Echo Bridge,



Inlet End of Inverted Syphon.

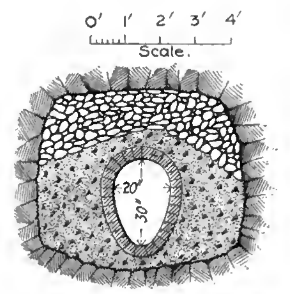


Discharge End of Inverted Syphon.

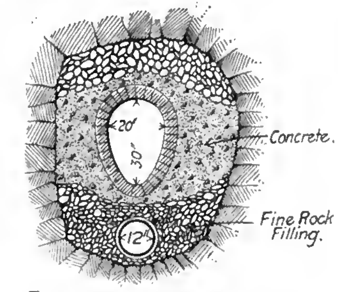
crosses the river by an inverted syphon under the bridge, consisting of two lines of iron pipe, one 6 inches and the other 8 inches in diameter, and each about 250 feet long. From the end of the inverted syphon the sewer, again 20x30-inches in size, passes through a second rock tunnel 389 feet long and follows along the bank of the river on the Needham side nearly to Elliot Street, where it turns and recrosses the river. This crossing is a gravity sewer of 16-inch iron pipe. Near this point the extension proper ends, being connected with the lateral system which provides for the drainage of nearly all the village of Newton Upper Falls.

At the upper river crossing of 16-inch pipe the grade of the sewer is well below the bed of the river, and connection was made through the ledge to the river bottom for the purpose of flushing the sewer when necessary. As far down as the second river crossing there is a 12-inch subdrain under the main sewer, which discharges into the river near the inlet end of the inverted syphon.

As the sewer is from 6 to 12 feet below the surface of the water in the river, great care had to be taken in the construction to build the sewer and manholes perfectly water-tight. This was accomplished by the use of cast-iron pipe laid with leaded joints, and by the use of concrete and steel in the construction of the manholes. In some cases the manholes, in addition to being reinforced with expanded metal near the outer surface, were lined inside with ⅜-inch boiler iron. The accompanying illustrations show the principal details of the manholes at each end of the inverted syphon. The section



Typical Section in First Tunnel.



Typical Section in Second Tunnel

through the manhole at the inlet end shows where the subdrain leaves the main sewer to discharge into the river. As the bed of the river is ledge a trench was excavated 5 or 6 feet deep, and the syphon pipes bedded in loose stone at the bottom.

In order to insure the tunnel portions of the sewer being water-tight, the brick rings were surrounded by the thick mass of concrete shown on the typical cross sections. As the city owned no air compressor or other equipment for tunnel work, it was thought best to advertise this part of the work; and specifications were drawn up for driving the tunnels and building the sewer therein. Only one bid was received, and as that was not satisfactory in amount, it was rejected and the work undertaken by the city forces. A 12x16-inch Rand air compressor rated to give 251 cubic feet of free air per minute was rented and placed on the Needham side of the river. This compressor was run continuously day and night, and supplied air to the three headings in the tunnels. The work of driving the tunnels and constructing the sewers was in charge of Mr. R. K. Porter, as inspector. There were used on the work 6,150 pounds of dynamite, and no accident of any kind occurred.

The Best Aluminum Wire Joint, out of 28 different types, is made as follows, according to Mr. W. M. Morrison, in a paper presented to the Institution of Electrical Engineers: The two ends of the wires are bent round each other, or simply butted together, they are then surrounded by a cigar-shaped mould in two halves which are clamped together and molten aluminum run in at a hole in the top. The mould is then removed.

The Vouvry Water-Power Development of 3,117-Foot Head.

At Vouvry, Switzerland, there is a water-power plant now in operation which bears the distinction of possessing the highest head of all water-power developments yet attempted, certainly on a large scale. It has a total head of 950 meters, or 3,117 feet, and plans have been completed to utilize a total of 10,000 horse-power. Although construction work has in general been carried on to realize ultimately this capacity, the present installation comprises but one-fifth of the total contemplated power. Supplementing a brief reference that was made to this plant in The Engineering Record of May 17 may be added the following interesting information gathered from an article in a recent issue of "Le Génie Civil."

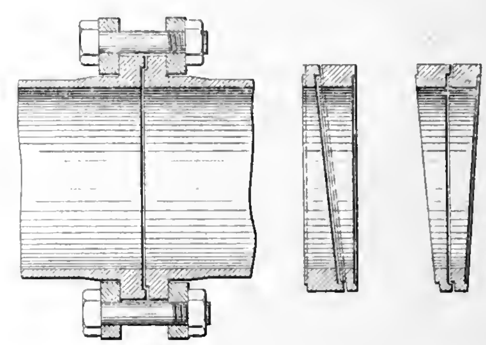
The plant receives the water from Lake Tanay and the works are located at Vouvry, on the left bank of the Rhone, a short distance above the place where that river empties into Lake Leman. The surface of Lake Tanay is at elevation 1,416 and the turbines in the power-house are at elevation 466, so that the available head attains 950 meters. The lake has a superficial area of 111 acres and its watershed, an area of 1,850 acres. According to M. Boucher, the author of the project, the total volume of water will amount to 2,900,000,000 gallons annually, or 12.3 cubic feet per second. Under a fall of 3,117 feet and allowing for turbine and other losses, the normal power of the fall would be, with a constant rate of discharge, 3,100 horse-power. This would amount in a year to 27,150,000 horse-power-hours. Lake Tânay can be regarded, however, as a natural reservoir, so that if water is drawn, say during only 1,000 hours per year, the power available during that period would be 27,150 horse-power. Similarly, if power is required during 2,000 hours, the average output figures 13,575 horse-power; if during 3,000 hours, 9,050 horse-power. The Vouvry plant has been exploited to aid a 2,500 horse-power water-power plant at Vuargny on the other side of the Rhone. Electric energy is distributed to a large number of towns in the valley of the Rhone by means of transmission lines which aggregate in length some 80 miles, supplying 63 stations with 97 transformers. In all 20,000 lamps of 10 candle-power are served and 450 horse-power in motors. The equipment of the two new plants has been selected so that the output of both can be transmitted on the one system of conductors, both plants possessing alternators of the same voltage and periodicity.

The intake at Lake Tanay will consist of a heading driven at an elevation 85 feet below the normal level of the lake into a well 100 feet deep, into which the water now enters near the top. From this well runs a tunnel of slight pitch, the entrance to which consists of five openings in a masonry wall provided with iron-covered stop-planks. Three of the openings hold short cast-iron pipes 15.75 inches in diameter, each fitted at the mouth with a sort of conical cast-iron stopper acting as a gate or valve; the fourth is a manhole 31 inches in diameter and the fifth is a by-pass pipe 4 inches in diameter for setting up a counter-pressure when it is desired to open the main pipes, that is, to lift the stoppers. When the level of the lake is at its maximum, a force of about 3 tons would be required to lift each stopper, which is suspended by a lifting chain, were it not for the by-pass.

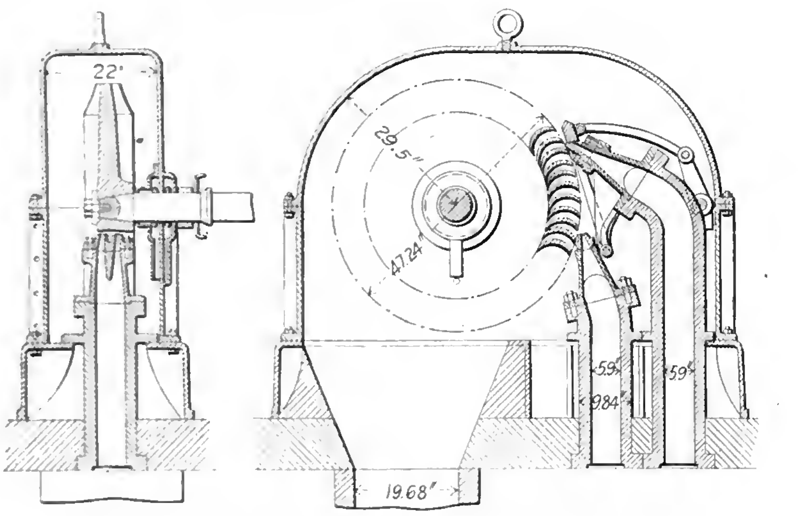
The tunnel is 984 feet long and has a cross-section of 32.3 square feet. About 100 feet from its lower end an overflow tunnel runs from it at a right angle. A little above the point of intersection of these tunnels, the intake tunnel appears to be closed off, except for three 15.75-inch openings, two fitted with float valves and the third with an emptying valve. A little below the intersection there is a small dam forming a basin of water. When the turbines are operating, there is a call for water, the water level lowers, the floats of the valves drop and the corresponding openings discharge. When the works shut down there is no demand for water from them, the floats rise and the flow of water ceases. To lower the level of the lake, in order to prevent passing the maximum level, the counterweights of the float valves are loaded and if this does not suffice the emptying valve is opened and the water passes through the overflow tunnel.

The lower end of the intake tunnel is of masonry and provided with an emptying valve. Here begins the pressure conduit of sheet-steel pipe 31.5 inches in diameter and 325 feet long, followed by a pressure tunnel about 1,000 feet long. From the latter the 31.5-inch steel pipe continues, with an inclination of about 5 per cent., for 3,900 feet, terminating in three branch pipes 19.7 inches in diameter. From one of these the conduit descends to the works, while the two others are closed to be used when future needs require them. At this point the head has scarcely attained 69 feet, but from there on it increases very rapidly. Here an automatic valve has been provided to close off the conduit in case of a break below, and there is an air pipe 15.75 inches in diameter and 82 feet high.

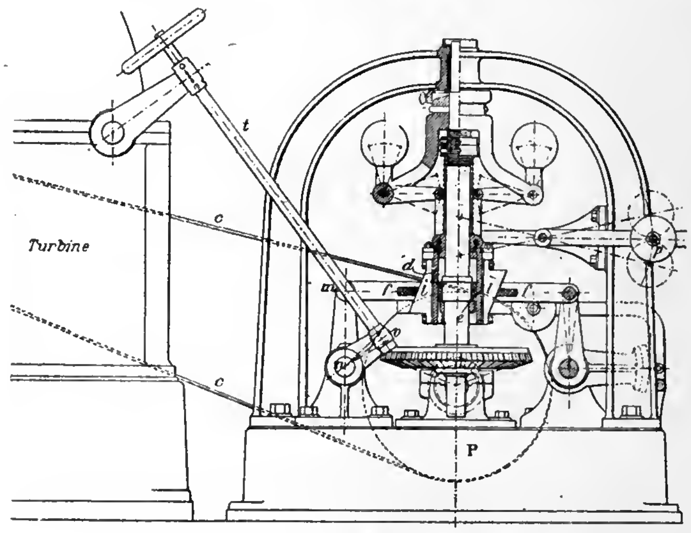
The length of the conduit on the steep slope is 6,360 feet and the corresponding difference of level 2,952 feet. For 2,083 feet the conduit has an outside diameter of 19.7 inches and a thickness varying from 0.27 to 0.45 inch. It then subdivides into two branches 13.4 inches in outside diameter and 4,260 feet long, with a thickness of 0.31 to 0.71 inch. The pipes subjected to heavy pressure are of Siemens-Martin steel, without riveting; the largest are welded by hand, the others in the rolling mill. The pipe joints are made by the use of bolts through loose rings held on each pipe section, as indicated in an accompanying illustration. Water tightness is obtained by the introduction in the joint of a ring of copper enveloping a ring of asbestos having the form of the interior half of a torus, that is, a ring of half-round cross-section, and an initial thickness of 3 millimeters, 0.12 inch, and reduced, after tightening, to a fraction of a millimeter.



Straight and Angle Pipe-Joints.



Sections of the Duvillard 500-Horse-Power Turbine.



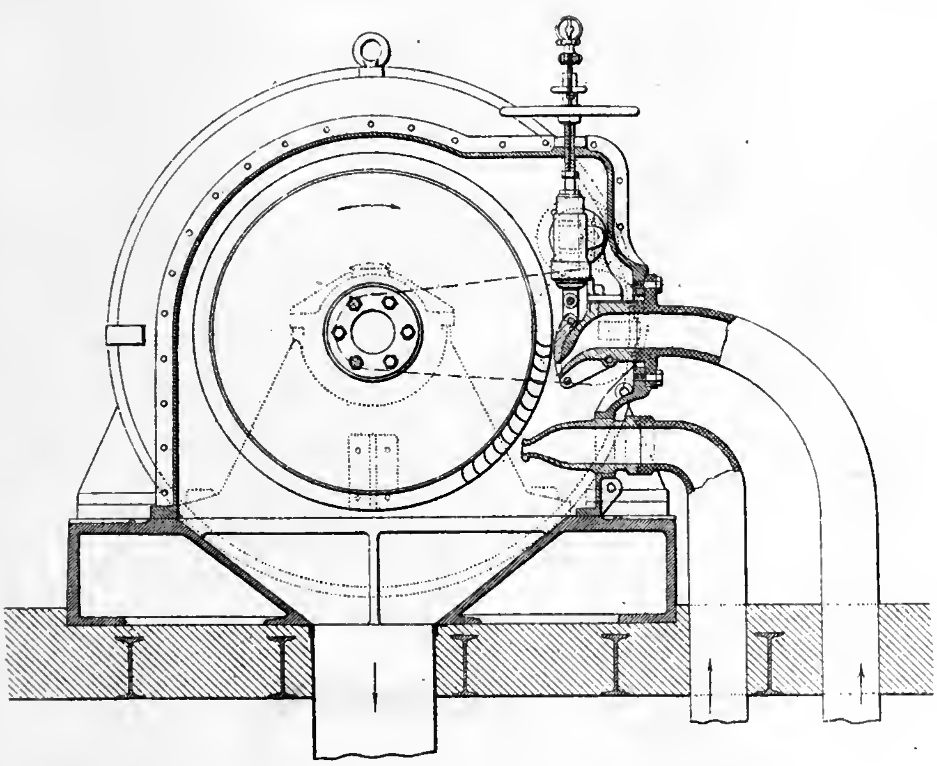
Elevation of the Michaud Governor.

The conduits are buried in a trench 5 feet deep to prevent freezing when the flow of water is interrupted. They thus follow the contour of the ground, which makes necessary a considerable number of changes of direction. The method of providing for these changes is indicated in an accompanying drawing. It is obtained by means of a pair of false joints composed of two similar pieces with slanting faces, which by turning one on the other can make the adjoining connecting pieces of pipe assume any desired angle, as much as 10 degrees. The pressure attained at the lower part of the pressure conduit system amounts to 10,667 pounds per square inch. The conduit being laid underground neither anchors nor massive piers were necessary. The different sections, or lengths, of pipe weigh from 1,760 to 2,200 pounds and are 16.4 to 32.8 feet long. They were carried to place by means of an aerial cableway, which has been left for the future installation. Each conduit has at its lower end a hand operated valve with by-pass.

The power-house is 46x216 feet, and large enough to house twenty generating units of 500 horse-power each. The roof of the building is of tile supported by iron trusses and the whole structure was designed to be fire-proof. The piping and the valves commanding the turbines are placed in the basement. In addition to a stop valve, the supply pipe to each turbine has a hydraulically operated valve controlled from the station switchboard. The piping subdivides into two branches after leaving the hydraulic valve, one branch supplying two turbines built by the Societe de Constructions mecaniques de Vevey and the other supplying two turbines made by M. Duvillard, of Lausanne.

The turbines are of the Pelton type constructed of cast-iron disks carrying cast-iron curved blades on both sides near the rim. Both turbines are shown in the drawings. Each turbine of both makes is supplied with two nozzles, one fixed and the other capable of regulation. Each of the nozzles is designed to discharge 1.85 cubic feet per second, which will furnish 500 horse-power. The turbine is put in operation by means of the regulated nozzle and when normal conditions have been reached, this nozzle is cut out and the turbine operated from the fixed nozzle alone, which, having no moving pieces, is less liable to wear. Experience has shown that this precaution was unnecessary as the wear on the turbines and nozzles proved much greater from the impurities in the water than from its high velocity. Each nozzle has two converging orifices corresponding to the two sets of blades on the two faces of the rim of the moving wheel. The pipe which supplies each turbine is 5.9 inches in diameter, has a hand valve and divides into two branches corresponding to the two nozzles. Each branch is likewise 5.9 inches in diameter, and is fitted with a hydraulic piston valve operated from the switchboard. Each turbine is mounted on the alternator shaft; it is 47¼ inches in diameter and runs at 1,000 revolutions per minute.

For regulation, the Duvillard turbines are controlled from a governor shown in one of the drawings. The apparatus is driven from the turbine by means of a belt, c, and actuates the regulated nozzle by means of a rod, t. It consists of a base carrying at its lower part a pair of bevel gears which are moved by means of the belt. The gears turn a vertical shaft carrying a small eccentric, e. The same shaft supports a fly-ball governor attached to a sleeve, d, to which is fastened a steel cam, i, this forming a parallelogram of which the oblique sides are finely toothed. The eccentric gives the sleeve a movement in a horizontal plane and this in turn communicates the movement to the cam. Around the cam is a steel frame which has a slightly greater play than the stroke of the eccentric, which is 0.118 inch, and to this frame is connected the rod t, and also a system of links, m, n and o. When the balls of the governor change their position, the sleeve and the cam are moved. This being freely balanced within the frame, f, it encounters one of the oblique sides, engages on one side or the other but only communicates to the frame, at each throw of the eccentric a displacement less than the throw. When this small movement is accomplished, the cam becomes again completely free and rises or descends without exacting any effort on the part of the fly-ball mechanism. The jets from the nozzle exercising a certain reaction upon the tongues or blades, by which the regulated nozzle is cut off, the tongues would have a tendency to open during the fraction of a turn when the frame is free from the cam. This has been remedied by a small counterweighted brake actuated by the links, m, n and o. The fly-ball portion can also be regulated and there are two counterweighted levers to arrange for a variation within chosen limits of the number of revolutions desired.



Cross-Section of the Vevey 500-Horse-Power Turbine.

The alternators produce single-phase current under a pressure of 5,500 to 6,000 volts with a frequency of 50 cycles per second. Including the acquisition of the water rights, the installation cost about $160,000, which for 2,000 horse-power, means $80 per horse-power. With the additional 2,000 horse-power now in course of installation, the cost per horse-power is about $55.

An Unusual Blasting Accident.

An unusual, if not unique, accident occurred recently near Niagara Falls. The following account of the blast and its results is taken principally from the description published in "The Iron Age":

The Ontario Power Company are excavating a power house site at the water's edge on the Canadian side, not very far below the Horseshoe Fall. The site is immediately opposite Goat Island, of the New York State reservation. The river at this point is the widest below the falls. Heavy blasts were used in order that the excavated material might be thrown into the river and thus do away with handling it. The talus, as well as a portion of the solid base of the cliff, was being broken away, and as the river is very wide, fully 2,500 feet, and the New York cliff was expected to act as a stop for any stones that might be carried across the river, no effort was made to hold the blasts down. The work was in direct charge of the Ontario Power Company.

At noon on Tuesday, October 28, a blast of unusual size was to be discharged, and word was sent to the New York State reservation officials to keep people away from the Goat Island bluff immediately following the noon hour. Such warning was given. At 12.15 o'clock the blast was discharged. It hurled a wonderful mass of rock and dirt into the air, and so terrific was the force of the blast that a tremendous shower of rock fell upon Goat Island, having been carried all the way across the river and 200 feet up in the air to the island surface. The river, usually clear and green, had its color turned to that of mud, and people who stood at Table Rock, on the Canadian side, state that the New York shore was hidden by the curtain of rock that ascended high above the cliff tops.

One 200-pound slab, 32 inches long, nearly 9 inches thick and about 14 inches wide, ascended very high in the air and whirled round and round like a wheel as it flew across the river, up over Goat Island to a point fully 500 feet back in the forest growth, making a flight of fully half a mile. In descending it cut a big limb off a tree and plunged downward, striking two reservation employes, who were walking side by side along an island path. Both died from their injuries.

At the coroner's inquest it developed that the blast contained 2,500 pounds of powder and between 200 and 300 pounds of dynamite. Both black and granulated powder were used. The general direction of the blast was at right angles with the water. In one drift and shaft combination were placed 60 kegs of powder and 100 pounds of dynamite. In a small shaft tunnel 37 kegs of powder and 50 pounds of dynamite were placed. Besides this there were two large bowlders, a box and a half of dynamite and three kegs of powder. In addition to this there were drill holes. All the charges were tamped.

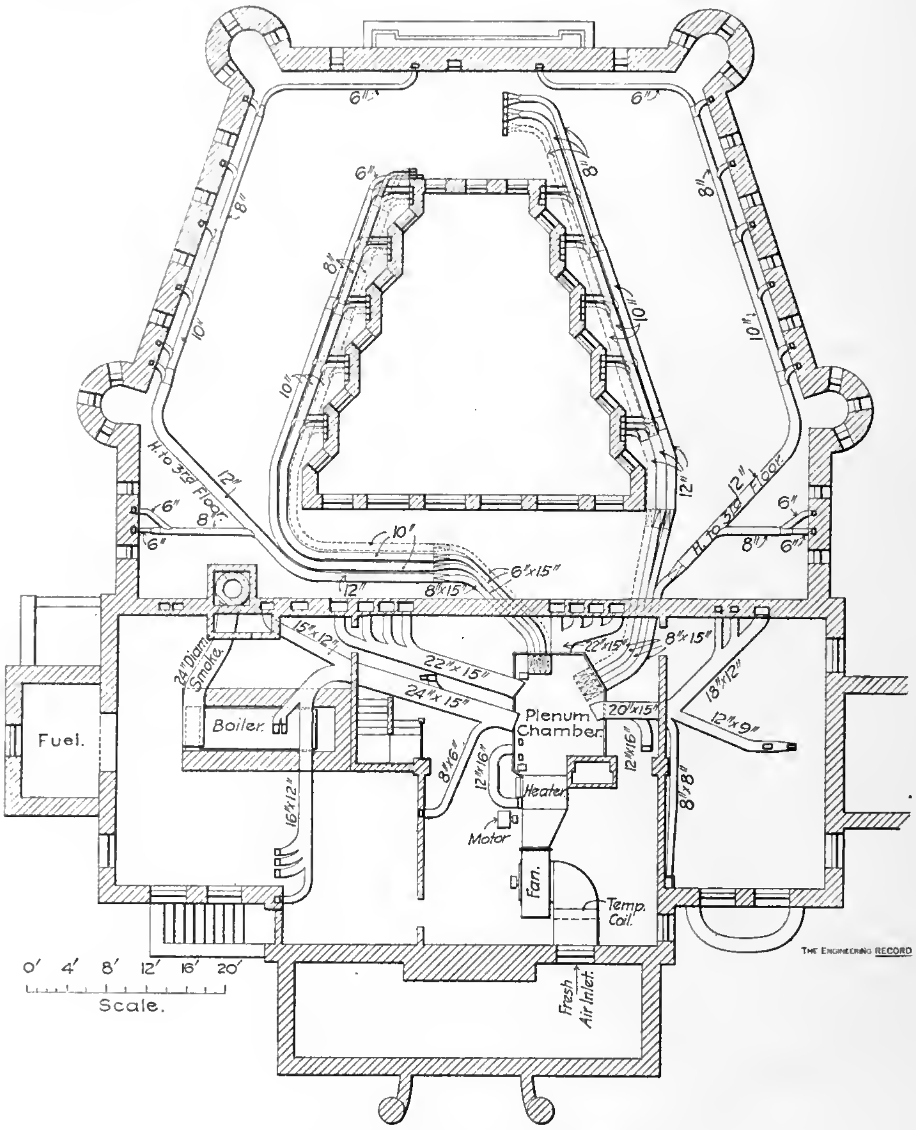
The American Society of Mechanical Engineers will hold its 46th meeting at its house in New York, Dec. 2 to 5. The following list of papers has been announced: "A Rational Solution of the Problem of Weights and Measures," by Prof. Sidney A. Reeve; "The Metric System," by F. A. Halsey; "Entropy Analysis of the Otto Cycle," by Prof. S. A. Reeve; "Apparatus for Obtaining a Continuous Record of the Position of an Engine Governor," by J. C. Riley; "Flywheel Capacity for Engine-Driven Alternators," by W. I. Slichter; "Heat Resistance the Reciprocal of Heat Conductivity," by Wm. Kent; "A Forty-four-Foot Pit Lathe," by J. M. Barnay; "Finer Screw Threads," by Chas. T. Porter; "A Surveying Instrument in the Machine Shop," by C. C. Tyler; "Gift Propositions for Paying Workmen," by Frank Richards; "Deflections of Beams by Graphics," by W. Trinks; "Rotary Pumps," by J. T. Wilkin; "Filing System for Office Use," by H. M. Lane; "Analysis of Commercial Value of Water-Power per Horse-Power per Annum," by A. F. Nagle; "Centrifugal Machines," by B. Viola; "Oil-Testing Machine and Results," by Prof. A. Kingsbury. For topical discussions the following subjects have been presented: Smoke consumption, elastic resistance, oil burners, oil separation from steam and oil-tempering of steel.

Heating and Ventilating the Akron, O., Jail.

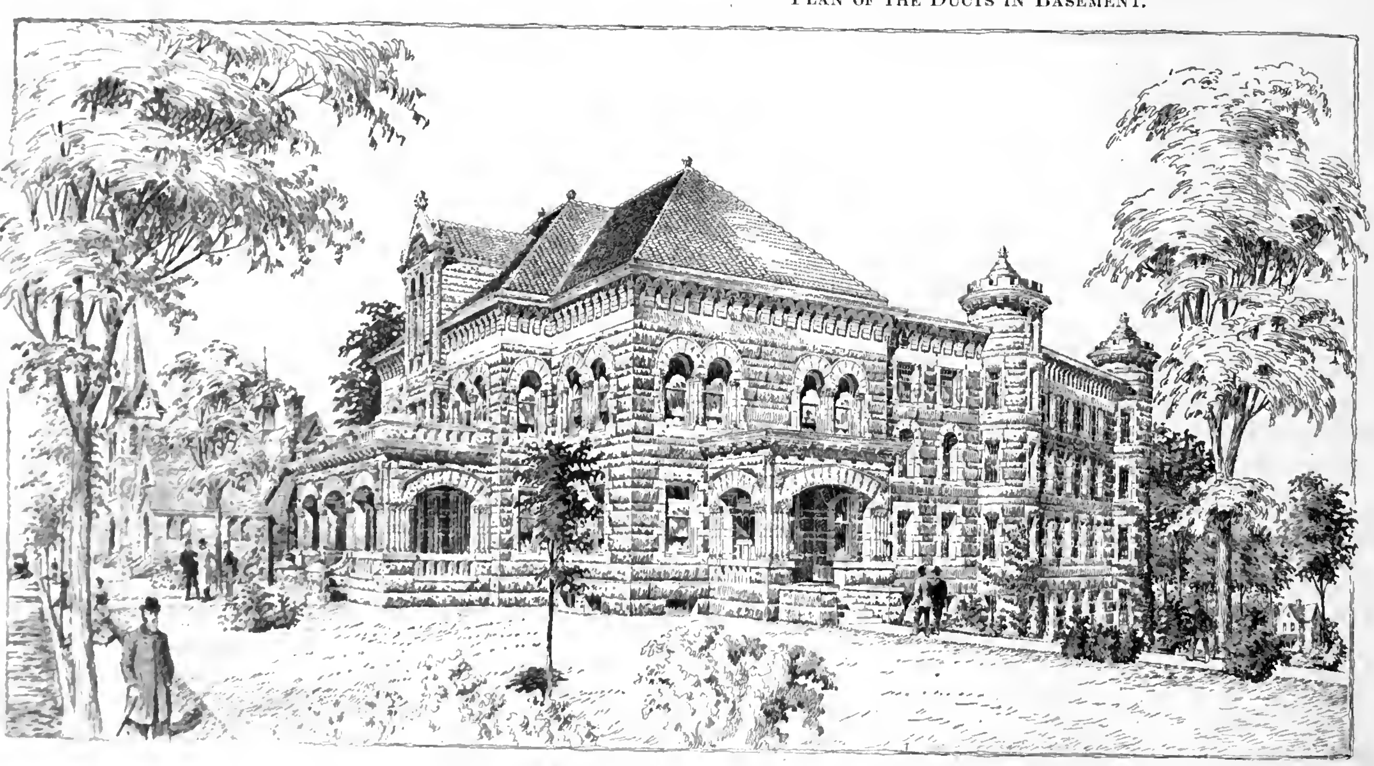
A county jail is nearing completion at Akron, which is a radical departure from the general plan of prison buildings, it being so arranged that while the inmates cannot see one another, they are plainly visible to the turnkey at all times. This allows for a separation of the prisoners, which prevents any intercourse between them. It has also been the aim in this building to produce an agreeable and attractive exterior, to disguise as much as possible the purpose of the structure. The interior is designed with special attention to making it sanitary and fireproof, and besides its commendable features as a prison has an extensive ventilating and heating system. The building is in two parts with separate entrances; the front part constitutes the sheriff's quarters and consists of two stories, a basement and attic; the rear, or prison, section is trapezoidal in plan and encloses a triangular court open to the sky. The prison contains four stories, including the basement, of which all but the upper floor are for men. The top story is the prison for boys and females, and is slightly different in construction from the plan here shown. The basement of the residence half is utilized for the ventilating and heating plant for the entire building, and a part of the second floor over the sheriff's office is fitted up as the prison hospital ward, with adjoining attendants' rooms and complete toilet conveniences.

The open triangular court in the prison portion is faced with white enameled brick so as to reflect as much light as possible to the cells and to allow of washing down the walls with a hose. There are six cells on both sides of each men's story, making in all a total of 36 cells. Each cell has a window into the court, but is inaccessible from any outside rescue, as the court can only be reached through the jail corridors. The windows are arranged in a series of receding bays and staggered in such a manner as to prevent the prisoners seeing one another, but to enable them to see and hear any one addressing them from the speaker's gallery. This makes it unnecessary to assemble them in one room, where they would be able to communicate with one another. The cell windows are to be heavily grated from the inside on a plane with the inner steel lining of the cells, while the sashes are on the court side of the wall, wholly inaccessible to the prisoners; they will have patent locks which are manipulated by the keeper from the balcony extending around the inner court. The floors of these balconies will be of glass so as not to cut off the light to the cells beneath.

There will be provided in each cell a small lavatory bowl and an extra heavy, buff-colored earthenware water-closet, which, for sanitary reasons, will have no wooden seat. All pipes, valves and fittings will be located in pairs in the triangular compartments at the corners of the two contiguous cells they supply, and may be reached by the plumbers, through a locked door, from the corridor. The fixtures will be operated by push buttons from the cells, with

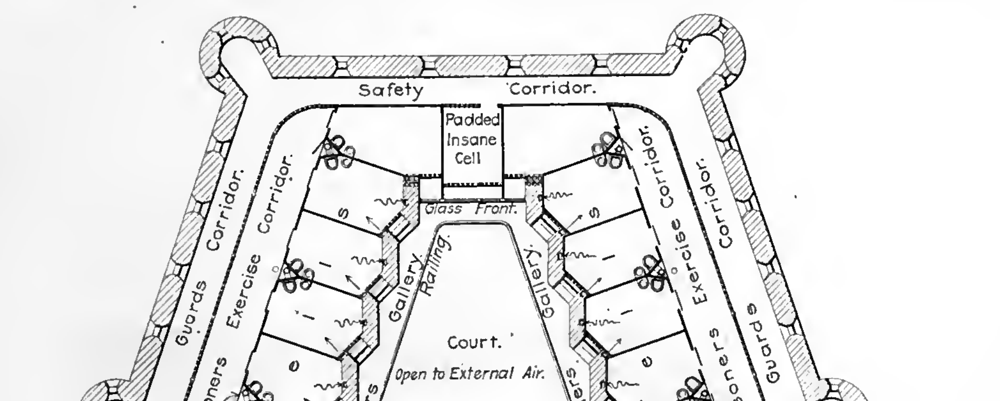


PLAN OF THE DUCTS IN BASEMENT.



THE SUMMIT COUNTY JAIL, AKRON, O.

nothing in the cells which the prisoners can mutilate or destroy, and the water will be supplied by time tanks, flushing only at the specified hours at which they are set, to prevent any malicious waste of water. An electric transmitter will be located just outside each cell window, connected with a sensitive megaphone receiver in the jailer's office, which will report any communication of prisoners through their cell windows, or any unusual noises, such as filing, sawing or other indications of attempts at escape. A similar device will be placed in the padded insane cells to detail all of the ravings or relapses of the inmates to the office. There will be one of these insane cells on each of the three men's floors located at the apex of the court. On the court side they will have glass fronts backed with iron



Plan of First Floor.

bars, allowing unobserved inspection, day or night, from the jailer's corridor.

In the main partition between the jail proper and the sheriff's apartments there will be a number of conical shaped peep-holes through which the authorities may survey all parts of the jail without being seen by the prisoners. The prisoners in any row of cells will be permitted to exercise one at a time in a caged corridor running the length of the row, from the end of which they may talk across the guard's corridor to their visitors, who are allowed to come only as near as the visitors' cage. The exercise corridor is divided off from the outer guards' corridor by an open barred grating and both will be lighted by narrow windows in the external walls, which will be too small to permit of a person crawling through, but will afford convenient port-holes to defend the jail in case of a mob attack. The source of light to the cells being from the windows on the court side, the cell doors are made of solid plate with no gratings; therefore a prisoner in the exercise corridor cannot see or talk to any other prisoner. The doors will be opened and closed by locking devices operated by levers in the guards corridor. Food will be served on trays through traps in the cell doors, and will be elevated from the kitchen to the different floors by a dumbwaiter.

A shower bath and a laundry tray for the prisoners to do their own washing will be located at the forward end of each exercise corridor, with hot and cold water mixing chambers and measuring tanks in the outer corridor so that the keepers may control and limit the use of water. Instead of the usual iron cots, hammocks of heavy duck bound with leather will be used in the jail, for economical as well as sanitary reasons, as they can be readily fumigated or burned if unfit for further use, and may be cheaply replaced. The top floor is divided into two parts, one-half being for boys and the other for women. There are four cells in each section, and they are arranged along the outer walls instead of the court walls. As these cells depend on the exterior windows for their light, the top row of windows are made wider and are protected by substantial ornamental grilles. Their great distance from the ground could, however, offer no chance of escape. To eliminate as far as possible all prison appearances, the cells for the retention of boys and women will have plastered walls and oak doors and floors.

The ventilating and heating of the entire building, including the jail and sheriff's residence, is done by a combined forced and induced hot-air system. The circulation is established by a large motor-driven blower of the Buffalo Forge Company's make, which takes its air through an inlet 14 square feet in area and containing a steam coil for slightly tempering the air in the severest weather. The blower discharges partly through a heater and partly through a by-pass into a plenum chamber. The hot and cold air are kept apart in this chamber by a diaphragm and are mixed upon entering the ducts which convey air to the various prison sections. Each row of cells on each floor has its individual main duct in the subbasement from which a riser is taken to each cell. The temperature in each of these mains is automatically regulated by two mixing dampers at the plenum chamber, which are controlled by a thermostat located in one cell of each group, and in such a manner that it cannot be tampered with. The risers to the men's cells are in the court wall, and those to the women's and boys' cells in the external wall. There are four sets of the former; one carries vitiated air from the basement cells; the next supplies the basement with fresh air and is then blocked off, and the remainder of the flue vents the first floor cells. Similarly, the next flue supplies the first floor and vents the second, and the last supplies the second floor. Each duct is carried in a chase in the wall and is but 4x8 inches in area, so that it offers the prisoners no possible means of escape. To give a uniform or any desired distribution of air to the separate cells the branch to each riser is provided with a damper to regulate the quantity passed. The vent flues of all cells and other rooms lead to the attic and are there connected to a 42-inch disk fan, which is driven by a direct-connected 3½-horse-power General Electric motor.

The accompanying basement plan shows the location of the blower, heater, etc., and the form of the main distributing ducts in the basement. The plenum chamber is divided by a diaphragm to separate the hot and cold air, and each duct is provided with two mixing dampers, one opening into each compartment. These two dampers are connected together so that opening one closes the other and vice versa, the extent and direction of the movement being determined by the thermostat. It will be seen from the plan that the residence part of the building is supplied for the most part by systems of rectangular ducts of tree form, as distinguished from those for the prison division, which, as was shown, are in the form of continuous mains, cylindrical, except near the plenum chamber, where they are rectangular, and decreasing in diameter as risers are led from them. The ducts and risers for the sheriff's department are of various sizes, according to the volume and location of the rooms they supply. They are taken from the upper or hot-air part of the plenum chamber, and the temperature is regulated with automatic thermostats, which operate on volume dampers placed in the flues running to these rooms.

The blower is a 90-inch fan with a 64x32-inch wheel and runs at 225 revolutions per minute. At this speed its capacity is 13,000 cubic feet per minute, which is sufficient to change the air in the entire building once in every ten minutes. The fan is belted to a 5-horse-power motor, built by the Akron Electrical Manufacturing Company. The tempering coil contains 180 square feet of heating surface and tempers the air to about 45 degrees. It is only used in the coldest weather. The regular heater consists of five sections of 1-inch pipe coils, giving a total of 900 square feet. Steam is supplied to the heater and tempering coils by a 48-inch horizontal tubular boiler, 12 feet long, made by the Pennsylvania Boiler Works, of Erie, Pa. The boiler is located near and delivers its gases of combustion to a cylindrical stack 2 feet in diameter.

The combined area of all the ducts opening into the plenum chamber is 16 square feet, and the velocity of the air entering them at this place is, on the average, 815 feet per minute. From this rate of discharge the velocity into the cells is reduced to about 400 feet per minute, and the quantity discharged into each cell can, on this basis, amount to 90 cubic feet in one minute. In the corridors the velocity is less, the air entering at about 250 feet per minute. The corridor registers are all in the front end and are supplied by flues in the dividing wall between the jail and dwelling. The vent flues and registers are at the other end in the exterior wall. It may be interesting to note in accordance with this calculation that of the total air supplied only 17½ per cent. goes to the residence portion. In other words, the prison receives nearly five times as much air as the sheriff's apartments.

Mr. F. O. Weary, F. A. I. A., of Akron, is the architect of the building, and the patentee of the type of prison described. The ventilating and heating apparatus was designed and supplied by the Buffalo Forge Company, of Buffalo, N. Y., and the complete equipment was installed by Kraus, Kirn & Company, of Akron.

A Large Power Distribution Scheme has been authorized by Parliament to supply power to the industrial region of the lower Clyde River in Scotland. The district extends about ten miles on each side of the river and about twenty miles up and down stream from Glasgow. The area covered is about 700 square miles, and three generating stations are to be erected. The scheme has been prompted by a group of manufacturers to obtain cheap electrical power. This part of industrial Scotland contains about 1,200 works, many of which are large iron and steel works, coal mines, shipbuilding yards and chemical works. The three generating stations are to be built at Motherwell, Yoker, and Crookston, but it will not be necessary to construct the third station immediately. It is intended to install in each of the first two stations a plant of about 4,500-kilowatts capacity. A radius of 14 miles from these stations covers practically the whole district in which the company will be allowed to distribute its power, but a large proportion of the works are located within a radius of 6 or 7 miles of the stations. When the stations are in operation, they will probably be coupled together electrically, enabling them to share the loads and average up their power factors or to supplement or aid each other in any emergency. The capacities of the respective stations will ultimately be about 10,000 kilowatts each at Motherwell and Yoker, and 5,000 at Crookston. Of the 710 square miles covered by the scheme, only 13 are at present supplied by electricity. The authorized capital of the Clyde Valley Electrical Power Company is $4,500,000, with borrowing powers of $1,500,000. The total cost for plant on the transmission lines is estimated at over $2,000,000. The electrical apparatus, which will comprise polyphase alternating-current generators and transformers for high voltage power distribution, rotary converters for the supplying of direct current, etc., has been contracted for with the British Westinghouse Electric & Mfg. Co. Messrs. Strain & Robertson are the engineers of the Clyde Valley Electrical Power Company. Mr. Robert Robertson, of that firm, has recently spent some time in the United States investigating systems and methods of power transmission.

A New Drafting Machine.

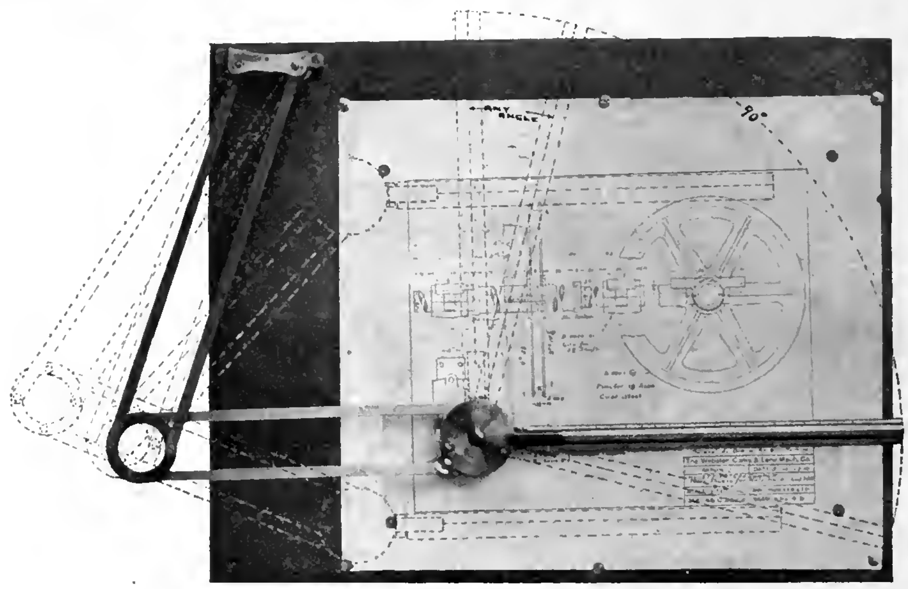
A drafting machine of considerable merit, because of its simplicity and adaptability to all kinds of drawings, has lately been put on the market by the Universal Drafting Machine Company of Cleveland, O. This new instrument is called "The Rapid Sketching Device," and is similar in construction to a larger and more expensive Universal Drafting machine manufactured by the same company. The striking advantage of the machine at first glance is that it combines the T-square, triangles, protractor and scale all in one. The manufacturers claim that a saving of half the time required by ordinary means is effected by their apparatus, since with it the draftsman can draw a line the exact required length at one operation, and may do angular work with as great facility as straight.

The apparatus consists of an ordinary drawing board, to the upper left hand corner of which is attached a mechanism for maintaining a movable scale always in positions parallel with its first setting. This is accomplished by two pivoted parallelograms, which in their action may be compared with the arm, elbow and hand of a man with his shoulder at the corner of the board, and possessing the ability scale will, as a consequence, lie flat on the paper, but may be raised slightly in moving from place to place, to avoid the rubbing of fresh ink lines.

The feature of the machine which is of greatest importance to its perfect working order is the tightness of the joints in the arms. After trying a number of kinds, the makers have finally adopted a hardened ground joint, which, on account of the slight pressure and speed with which it is used, will last indefinitely. The pin for the stops is made conical to compensate for wear. All parts are finished in nickel except the rods, which are coppered and oxidized.

The boards are regularly furnished 19x23 inches in size to accommodate sketches 18x20 inches, but by special order may be had in any size. The dealers will also supply for use with the machine, scales of any type, size or graduation.

The principal points of difference between this machine and the larger one are the use in the latter of two scales at right angles with each other instead of one, and a hinge at the corner where the mechanism is fastened allowing it to be swung entirely clear of the board. The head also has a hand wheel so that the moving and turning of the scales may be



METHOD OF USING THE RAPID SKETCHING DEVICE.

to move the scale to any part of the board, while continually pointing it in the same direction. The hand feature consists of two circular plates, between which, and on a stud through their centers, is mounted a lug carrying the scale. The lower plate is pivoted to the rods of the arm and cannot rotate. The upper plate serves as a protractor and may be revolved to any position and clamped by a set screw. It carries two stops on its lower face, which are adjustable to provide for wear or disarrangement. The scale, which may be of either the triangular or flat type, is fastened to the head by a chuck and may be readily removed, replaced or turned around so as to bring the desired edge into use. The scale moves freely between the two stops, with spring stops at 30, 45 and 60 degrees, these being the angles most frequently used. It is thus possible for the manipulator to set his scale at these positions quickly without referring to the protractor to be sure of their accuracy. In changing the setting of the protractor, all of the stops are simultaneously revolved, and the common relations of lines may be readily established on the new base. The flat horizontal placing of the rods in the arm gives rigidity where necessary, but also allows a desirable flexibility in a direction perpendicular to the plane of the paper. The done with the left hand, without touching either scale. The use of two scales saves some time and inconvenience because a horizontal or vertical line may be drawn without the swinging of the scale which is necessary in the other machine. The smaller one, however, has the advantage of compactness and portability, rendering it valuable for field work.

Brick Pavements as laid in Grand Rapids, Mich., have received particular attention in order to secure a smooth surface. City Engineer L. W. Anderson states in his last report that the sand cushion has been increased in depth and changed to a fine, soft sand. The brick, after being laid, are rolled with a hand roller, thoroughly culled, and then rolled with a 7-ton steam roller. It was feared that the heavy roller would chip the bricks, but such does not prove to be the case to any material extent. The pavement so laid, with joints well filled with Portland cement grout, gives a surface as smooth as asphalt blocks, although somewhat more noisy. The brick pavement is laid with a 5-year maintenance guaranty by the contractor. The contract prices for this brick paving on a concrete foundation for the year ending April 30, 1902, varied from $1.35 to $2.25 per square yard.

Removal of the Old South Tenth Street Bridge, Pittsburg, Pa.

By Willis Whited, Assistant Engineer, Department of Public Works.

The South Tenth Street bridge, formerly known as the Birmingham Bridge, was built in 1856 by the Birmingham Bridge Company, and crossed the Monongahela River about 1¼ miles above its confluence with the Alleghany. The bridge consisted originally of six covered Howe truss spans, about 220 feet long each, reinforced with arches. The crowns of the arches were somewhat below the top chords of the trusses and the springing lines about 10 feet below the bottoms of the trusses. The roadway was 20 feet wide, and the two overhanging sidewalks were each 5 feet wide. The banks of the river were gradually built out with slag from the numerous furnaces and with other materials, until the spaces under the two southerly spans and the north span were filled in and occupied by mills and railroad tracks. Then the south span was replaced by two 109-foot iron spans and the north span by an iron viaduct. When the south span was removed, the pier at the north end of it had been filled around so nearly to its top that it had sufficient stability to resist the thrust of the arches. The pier at the south end of the north span, however, was considerably higher, but the filling back of it was not so high, and so heavy timber braces, resting against the first pier of the viaduct, were placed against it when the north span was removed. As the river had been narrowed to but little more than one-half its original width it began to scour and the pier next south of the one which had been braced was undermined at its northwest corner so that it settled, with a movement of its top of two or three feet toward the north. This movement acting through the arches, brought a heavy pressure against the next pier, and, in spite of the bracing, forced the top of it about 18 inches toward the north. The old bracing, which had become considerably decayed, was replaced with new and heavier timber, but the pier continued to move and stones began to fall away from it. Then the bridge was ordered removed, and the contract was awarded to Mr. C. M. Driver, of Allegheny.

The method of removal was quite simple. The roof and sides were taken off first; then all those parts of the arches above the floor were removed, and afterwards the sidewalks, parts of the top and bottom lateral bracing, as much of the floor as could be spared, and the bolts at the intersections of the diagonals were taken away. The top and bottom chords, which were continuous, were cut over the piers, and the span to the south of the undermined pier was first taken down. This span was removed first because it was feared that if the span to the north of it were taken down first the undermined pier, which leaned toward the north, would fall and let down the span to the south of it, thus blocking navigation in a part of one span and the whole of another with a mass of wreckage which would take considerable time to remove. This southerly span was dropped in sections by boring a hole in each timber of each chord about one-third the way from each end of the span, placing a small dynamite cartridge in each hole, and exploding all the cartridges simultaneously. The end sections were moored to the piers with long ropes, and a steamboat which lay in readiness towed the center section immediately to the wharf, and then came for the other sections in turn.

The adjoining span south was next blasted down in the same manner. The third span to the south, being over railroad tracks, had to be taken down with false-work. The remaining span, which was next north of the undermined pier, was then blasted down in the same manner as the other river spans. The undermined pier did not fall, but while it was being taken down it cracked badly in several places. A singular thing happened when this last span was blasted down: the two end sections came down so that their top chords caught against the ends of the top chords of the center section before it fell, forming an arch springing from the ends of the old arches resting against the sides of the piers. Thus the whole span was held up in a very dangerous position. A 2-inch line was made fast about 30 feet from the end of the span and a steamboat pulled till it broke the line, but the span still held. A 3-inch cable was then made fast about 50 feet from the end of the span, and the steamboat, by two or three heavy surges on the cable, pulled the span down.

The contracts for the new bridge had already been let, for the substructure to Mr. C. M. Driver and for the superstructure to the American Bridge Company. The latter company removed the two 109-foot truss spans at the south end with false-work, using a small hand derrick. Cars were run into a siding under the bridge, and the iron was loaded directly on to them. The north approach was a plate-girder viaduct crossing the yard of the Baltimore & Ohio Railroad, and was taken down with the same hand derricks and loaded on to cars beneath. The two river piers and the damaged portion of the north shore pier were taken down with a derrick boat as far as possible and the parts of the two river piers under water were blasted and removed, partly with a dipper dredge and partly with an orange-peel dredge. The piers were built on timber grillages resting on the bottom of the river, so there were no piles to pull. The timbers in the grillages were loosened up with a dipper dredge and lifted out with an orange-peel dredge.

The bridge had always been covered in, but never painted. Aside from ordinary wear and tear, nearly all the wooden truss members and wind bracing were about as sound as when first put into the bridge. The rods might have lasted 100 years longer, so far as could be seen, with a few exceptions. Practically the only woodwork that had decayed to any extent was the portions of each bottom chord over the piers on the down-stream (west) side. Those parts were nearly all very badly decayed. Over two of the piers there was scarcely anything left of the chord for several feet. This was attributed to the fact that rain in this locality is usually accompanied by a west wind and had beaten in under the bridge, on top of the piers, causing the bottom chords and the blocking under them to rot. The only rods or bolts that were badly corroded were the vertical rods which passed through the arches and helped to support the floor. These were about 1¼ inches in diameter and passed through oak blocks under the floor. Many of them were reduced to less than ¾ inches diameter where they passed through these blocks. All the timber in the bridge, excepting these blocks, was pine, and the iron in the pine was no worse corroded than that exposed to the air.

The backing of the piers and many of the face stones were a local blue-stone, the remainder being a local sandstone. Many of the exposed bluestones had crumbled and split considerably, but the sandstone had weathered reasonably well. The mortar, however, had nearly all washed out, in fact it was difficult to determine what it was made of. It was, doubtless, composed of lime and a poor quality of natural cement mixed with river sand. In massive masonry like the piers the air has so little access to the lime that it requires many years for it to harden, and an occasional flood in the meantime will dissolve out nearly all of it, especially if the mortar is mixed too lean. A poor quality of cement is also soon washed away. The grillages on which the piers were built were of pine and apparently as sound as when first put in. The work was carried through without accident by Mr. C. M. Driver, the contractor, under the supervision of the author.

Personal and Obituary Notes.

E. E. Blackwell, chief engineer of construction work on the Texas & New Orleans Railroad, was killed near Nacogdoches, Tex., while making an inspection.

Mr. Samuel Parsons, Jr., of New York, has been engaged as landscape architect to take charge of converting 1,400 acres of land into a park for San Diego, Cal.

Prof. George C. Caldwell has resigned as head of the chemistry department of Cornell University and has been appointed professor emeritus and lecturer in chemistry.

Mr. Burton J. Ashley, civil and consulting engineer in the founding and building of Zion City, Ill., has resigned as city engineer, after eight years' service in that connection, and has returned to Chicago to resume his private practice.

Mr. Gustave Bottinger has resigned as chief engineer of the Tennessee Central Railroad and the Tennessee Construction Co., and Mr. R. E. Harwood has been appointed to fill his position with the construction company, at Nashville, Tenn.

Mr. Edwin Reynolds, president Am. Soc. M. E., has been made consulting engineer of the Allis-Chalmers Company, and he is succeeded as chief engineer by Mr. Irving H. Reynolds, M. Am. Soc. M. E., heretofore general superintendent.

Mr. W. H. Marshall has been made general manager of the Lake Shore & Michigan Southern Railway, with headquarters at Cleveland, and has been succeeded as general superintendent by Mr. H. S. Storrs, formerly assistant general superintendent.

Mr. H. B. Davis, the present principal assistant inspector of buildings of the District of Columbia, has been promoted to the position of inspector of plumbing, succeeding Mr. O. L. Ingalls, whose appointment as engineer in charge of sewers and water-works in Manila, P. I., was recently announced in this column.

Prof. William H. Burr, of Columbia University, Mr. Rudolph Hering, of New York, and John R. Freeman, of Providence, have been appointed a commission to report on the available sources for the enlargement of the water-supply of New York, throughout the boroughs, and on means for the prevention of water waste.

C. K. Dixon, superintendent of the Omaha Division of the Illinois Central Railroad, at Fort Dodge, Ia., died November 20 at Cherokee, Ia., after five months' illness. He was 56 years of age and had been division superintendent with the Illinois Central for 15 years and in the service of that company for over 30 years.

Since completing the power plant for the Montgomery Water-Power Co., near Montgomery, Ala., Mr. Ethan Philbrick has also established an office in connection with the North & South Engineering & Construction Co., Chalifoux Building, Birmingham, Ala., which conducts a practice in water-power developments, in railway, bridge and foundation work and in industrial plant design.

Another active career, distinguished by many works of importance and prominence, was brought to a sudden end by the death from heart disease of Joseph Miller Wilson, of Wilson Brothers & Co., of Philadelphia, in his office in the Drexel Building, that city, November 24. He was born in Phoenixville, Pa., in 1838, was graduated from the Rensselaer Polytechnic Institute in 1858 and began engineering as assistant engineer with the Pennsylvania in 1860, being engineer of bridges and buildings on that road from 1865 to 1886. During this period, however, he became engaged in the practice of building engineering and designed some of the principal buildings of the Centennial Exhibition, the Drexel Institute, in Philadelphia, the elevated railway station work in New York, and many hospitals and penitentiaries for which he made a special study abroad. For years he was president of the Franklin Institute and was a member of the American Society of Civil Engineers, of the American Institute of Architects, of the Institution of Civil Engineers and of other societies of both art and science.

By the death on November 22 of Friedrich Alfred Krupp the world is the loser of a man who succeeded by the assistance of well selected employes; he made the steel works of Fried. Krupp, at Essen, Germany, world famous, while himself remaining sole proprietor. Although an authority on the art of steel making and an ardent experimenter, as is shown by the award to him early in the present year of the Bessemer gold medal from the Iron & Steel Institute, he delegated the management of his widespread interests to a directorate composed of fourteen men and devoted a great amount of his time, instead, to the amelioration, in housing and education, of his workmen and their families. It is popularly supposed that the steel works have been very largely engaged in the manufacture of armor plate, guns and general war implements, but it is variously estimated that 50 to 70 per cent. of the output of the works was consumed for industrial purposes, a fact which, it is stated, Herr Krupp was always anxious to publish. He was but 50 years of age, and had entire control of the works only since 1887, when his father died.

Details of an Architectural Contest for the plans of a $250,000 church for the city of Patras, Greece, are given in "Consular Reports" No. 266, for November. The architecture is to be Byzantine, and the edifice must accommodate 5,000 persons. Three prizes are offered, $2,000, $800 and $400. Further information can be obtained from Mr. Frank W. Jackson, Consul, Patras, Greece.

An International Fire Exhibition is to be held at Earl's Court, London, from May to October, 1903. Various forms of building construction will be exhibited, as well as fire-extinguishing and life saving appliances, fire stations and their equipment, water-works and their various connections, salvage work, ambulance service and insurance. Details of the scope of this exhibition are given in "Consular Reports" No. 266, for November.

The Louisiana Purchase Exposition, at St. Louis, will be lighted from the plant of the Union Electric Light & Power Company, for which both forced and induced draft will be provided. There are to be 26 boilers of 700 horse-power each, equipped with automatic stokers. There will be four forced-draft fans with 160-inch full housings, driven by 10x10-inch direct-connected vertical engines; and two induced-draft fans with 230-inch full housings driven by 9x10-inch double-cylinder double-acting upright engines. The fan and engine equipment for this work is being built by the Buffalo Forge Company.

The Construction of the Kew Bridge, over the Thames River in England, presents several unique features, which are described at length in "The Engineer." The bridge consists of elliptical masonry arches of 131 feet span and 20 feet rise. The cofferdams used in building the piers were constructed of 14x14-inch squared piles 39 feet long. Grooves were cut into the piles 2 inches deep, into which tongues of 4x2-inch elm were fitted, making a perfectly water-tight dam, requiring no calking except where the tongues had been broken. There were five tiers of cross-bracing, 12x12-inch timber being used mostly. The main ribs of the arch centers were arched steel girders, each varying in depth from its middle to either end, and designed to carry a loading of 600 pounds per square foot.

A Hydro-Electric Power development is proposed by the Snoqualmie Falls and White River Power Company which plans to divert the waters of White River, at a point about 25 miles from Tacoma, Wash., into an 8-mile canal which will discharge into Lake Tapps. The lake will be used as a storage reservoir and settling basin, from which a short canal and tunnel will lead the water to a penstock to feed five steel pipes, only one of which will now be laid, to supply the turbines under 450 feet head. The discharge will be into the Stuck River. The power-house is designed to accommodate a 50,000 horse-power installation eventually, but at present a building sufficient for an equipment of 10,000 horse-power will be built, with a machine shop annex. This plant will be connected with the existing Snoqualmie Falls transmission system by circuits about 5 miles long. The head-works will include a concrete inlet, a submerged dam across White River, and gates for controlling the flow into the canal, which will be 25 feet wide on the bottom, with 1½ to 1 slopes under water and 1 to 1 above, and will have a capacity with 6 feet depth of water sufficient for 60,000 horse-power, theoretical, at 450 feet head.

Duties on Imports into China, as determined by the new Chinese tariff taking effect October 31, 1902, and published in the "Advance Sheets" of Consular Reports, No. 1481, dated October 29, include the following items of interest to manufacturers and users of engineering supplies:

	Duty in cents per 100 lbs.
Iron and mild steel, new—	
Mill iron and forgings for vessels, steam engines and locomotives (25 lbs. or over)	12.54
Angles, bars, rough castings, plates and sheets	6.62
Bolts and nuts, nails (except wire), pipes and tubes	5 per cent.
Pig iron	3.55
Rails	5.92
Rivets and wire	11.83
Galvanized sheet iron	13.01
Steel bars, sheets and plates	11.83
Tool and cast steel, steel wire and wire rope	35.49
Brass bars, sheets, plates and ingots	54.42
Copper bars, sheets, plates and wire	61.53
Belting	5 per cent.
Cement, per cask of 400 lbs., cents	9.46
Hard wood beams	0.95
Soft wood beams, piles and piling (including Oregon pine and California redwood, on a thickness of 1 inch), per 1,000 superficial feet, cents	72.57
Materials for railways, the free import of which was provided for by agreements antedating the peace protocol	Duty free

Note.—The above values were converted from haikwan taels per picul. The picul equals 133 1/3 pounds. The value of the haikwan tael fluctuates, but was estimated by the U. S. Mint at 63.1 cents on October 1, 1902, which value was used in the conversions.

CONTRACTING NEWS

OF SPECIAL INTEREST TO

CONTRACTORS, BUILDERS, ENGINEERS AND MANUFACTURERS

OF ENGINEERING AND BUILDING SUPPLIES.

For Proposals see pages xv, xviii and xxvii.

WATER.

New Britain, Conn.—Water Comrs. have voted to construct a reservoir on Wolcott mountain in Southington, to occupy 56 acres and cost $75,000. The capacity will be 1,500,000 gals.

New Castle, Pa.—The West Pittsburg Water Co. has been organized by New Castle and Pittsburg capital. W. K. Hugus, of New Castle, is one of the incorporators, and is attorney for the Co., which will install a water system at the new town of West Pittsburg, near New Castle.

Buffalo, N. Y.—The Water Com. has reported in favor of rejecting bids, received some time ago, for hydrants and asking for new bids.

Lancaster, Pa.—At a meeting of the Special Water Com. of the Council held Nov. 19 to consider the proposition of the American Spring Water Co. to furnish the city with water for a period of 30 years at a cost of $30,000 per year, it was decided to refer the question to a sub-committee of four, they to consult an expert engineer, to pass upon the practicability of the proposition.

Massena, N. Y.—The taxpayers will vote on the question of the village purchasing the plant of the Tupper Lake Water Co. for $56,000.

South Atlantic City, N. J.—The contract for installing $30,000 water works is reported to have been awarded to Henry A. Miller, of Wilmington, Del.

Philadelphia, Pa.—Bids are wanted Dec. 2 for supplies for the Bureau of Water, Dept. of Pub. Wks., including brass fittings, cocks and valves (made in Phila.), wrought iron pipe, iron and steel, bricks, lime, cement and Belgian blocks, fire brick and clay, cast iron water pipe and castings, American refined lead, meters Class A A, asphalt and granolithic walks, electrical supplies, etc. Wm. C. Haddock, Dir. of Dept.

Meadville, Pa.—City Engr. W. A. Doane writes that the Councils have accepted the bid of the Phoenix Iron Wks. for 2 150-H.-P. vertical Manning boilers for the new pumping station.

Hudson, N. Y.—Engr. in Charge H. K. Bishop writes that plans for water works estimated to cost $225,000 will be completed about Mar. or Apr., 1903.

Oakland, Md.—The City Council has under consideration the proposition of H. G. Frederick, of Millersburg, Pa., for the construction of a system of water works, with 25-year franchise.

New York, N. Y.—Prof. Wm. H. Burr and Rudolph Hering, of New York City, and John R. Freeman, of Providence, R. I., have been appointed a Comn. to report on the available sources for the enlargement of the water-supply of this city, throughout the boroughs, and on means for the prevention of water waste.

Allegheny, Pa.—The Council has voted a joint resolution for a special committee, of which Morris Einstein and Chas. Kirschler are members, to confer with a committee from Pittsburg Councils regarding the connection of the water mains of the two cities.

East Orange, N. J.—The Condemnation Comrs. appointed last April by Chief Justice Gummere, consisting of Amzi Dodd, J. William Clark and Eugene Vanderpool, to appraise the value of the East Orange system of the Orange Water Co., which East Orange is desirous of acquiring, has reported the value of the plant at $425,000.

Summit, N. J.—The Common Council has appointed a committee, consisting of Wm. J. Curtis, J. G. Van Cise, and others, to confer with the Essex Union Water and Light Co., and learn the price at which the Co. will sell its water and light plants to the city.

Troy, N. Y.—Bids will be received Dec. 5 by the Bd. of Contract and Supply, for furnishing F. O. B. cars Troy, 5,900 tons of 30-in. cast iron water pipe and about 114,000 lbs. special castings. Bids will also be received on same date for constructing about 7 miles of 30-in. conduit line for conveying water to the city of Troy; alternate proposals for constructing a 30-in. cast iron conduit and a 33-in. riveted steel conduit. John Phelan, Comr. of Pub. Wks.

Niagara Falls, N. Y.—In a recent communication to the Bd. of Pub. Wks., City Engr. Walter McCulloh recommends municipal ownership of the water works; he estimates that about five acres of land are necessary for a slow sand filtration plant, each acre providing filtration facilities for about 6,000,000 gals. of water, and suggests that the present city plant be used as a water plant for the development of electrical power, the power to be transmitted to a new plant on the upper river. In said report the City Engr. states that the source of supply should be the Canadian channel on the far side of Grand Island; the estimated cost of plant suggested is placed at about $500,000, outside the expense of the purchase of the plant of the Niagara Falls Water Works Co.

Atlanta, Ga.—The Senate has passed the bill authorizing Atlanta to issue $400,000 bonds, to perfect the present system of water works.

Summerville, Ga.—The Senate has passed a bill authorizing this village to issue $25,000 bonds for water works improvements.

Bristol, Va.—The city has purchased the Moore and Mumpower lands, 3 miles north of the city, thus securing 8 mountain springs that will afford a water supply of 400,000 to 600,000 gal. a day. Local press reports state that the city will begin at once the construction of catch basins near these springs, and next spring a storage reservoir will be constructed.

New York, N. Y.—The following bids were opened Nov. 20 by R. G. Monroe, Comr. of Water Supply, for furnishing and laying water mains in various streets:

Items and Quantities.	Robt. L. Christie.	Norton & Dalton.	Jno. Cornwell, Jr.	F. Thilemann, Jr.	Henry Lipps, Jr.
Straight pipe, 1,700 tons	$31.00	$31.50	$30.00	$31.50	$32.00
Branches, 65 tons	58 00	57.00	60.00	58.00	58.00

Birnamwood, Wis.—Village Clk. S. A. Sprague writes that at the recent election it was voted to construct water works at a cost of $5,000.

Odell, Ill.—Press reports state that $5,500 water bonds have been offered for sale.

Crete, Ill.—The Council is said to be considering the matter of installing a water system.

Milwaukee, Wis.—In a recent report City Engr. Poetsch stated that a total of $37,457 is to be returned to the water fund for special water main extensions.

According to figures given out by the City Engr., the cost of the larger improvements which this city will make within the next 12 months will be $3,686,000. Among the larger undertakings will be the Kinnickinnic flushing tunnel which will cost $145,000; a new 20,000,000 gallon engine in the water works at a cost of $200,000 with the improvements; a $33,000 pumping station on the West side; Muskego Ave. bridge, $93,000; Broadway bridge, $125,000; Jones Island bridge, $125,000; track elevation and depression, $175,000; Washington Ave. viaduct, $400,000; First Ave. viaduct, $500,000, and a municipal lighting plant, and the conduits and appurtenances, $1,000,000. In addition to this there will be school improvements aggregating $865,000.

New Bremen, O.—This village has voted $28,000 bonds for the construction of water works.

Fremont, O.—The Fremont Water Works Trus. are reported to have closed a contract with the Shaw-Kendall Co., of Toledo, to install a pump plant at the local water works to pump the deep water wells. The new plant means an outlay of $10,000, and the Ingersoll-Sergeant Drill Co., of Cleveland, will furnish necessary air compressor and machinery.

Moline, Ill.—The City Council has accepted the bid of the New York Continental Jewell Filtration Co. for a filter plant to be built according to plans of Consulting Engr. Daniel W. Mead, of Chicago, Ill., at a total cost of $67,377; the contract calls for a concrete clear water reservoir, 750,000 gals. capacity; concrete filter tanks, 5,000,000 gals. capacity; filter equipment, 4,000,000 gals. capacity; and filter building, "steel truss roof," size, 130x72 ft.

Joliet, Ill.—A correspondent writes that this city is about to let the contract for constructing a 1,000,000 gal. reservoir at the water works. Estimated cost, $10,000. H. A. Stevens, City Engr.

Tenstrike, Minn.—This village is said to contemplate installing a system of water works in the spring.

Muskegon, Mich.—Local press reports state that the capacity of the city water works plant on Lake Michigan will probably be doubled by the installation of a 10,000,000 gal. per day additional pump without cost to the city. The Central Paper Co. has offered to install the pump if the city will supply them 4,000,000 gal. per day.

Sioux City, Ia.—The Water Works Trus. are said to be considering the advisability of erecting a new plant for the special protection of the stock yards district.

Marlinton, W. Va.—The Pocahontas Water, Light & Power Co. has been incorporated to supply Marlinton, Durbin and other places with water, light and power. The capital stock is $25,000. E. M. Arbogast and others, of Marlinton, are the incorporators.

Menasha, Wis.—The Common Council is said to be considering the question of installing a water works system.

Cleveland, O.—Water Works Supt. Bemis has asked the Bd. of Control for permission to advertise for 15,000 more water meters.

Marinette, Wis.—According to press reports the Menominee Water Co. desires to build and equip a pumping station at Poplar Point, and only awaits the action of the City Council in designating the source of supply and how far out in the bay the pipes shall be laid.

Kansas City, Mo.—John A. Rodgers, Secy. Fortuna Land & Mining Co., 502 B'way, writes that said Co. proposes to construct in the near future a pumping plant to drain ground for leasing purposes, and an electrical power plant.

Perry, Okla. Ter.—City Clk. F. F. Busch writes that at the recent election it was voted to issue $50,000 bonds for water works.

Ft. Morgan, Ala.—See "Government Work."

Geary, Okla. Ter.—Water works bonds to the amount of $27,000 are reported to have been sold.

La Harpe, Kan.—This place has engaged Burns & McDonnell, Kansas City, Mo., to make plans and specifications for a concrete dam, and extensions to the water-works system.

La Junta, Colo.—Bids are wanted Dec. 1 for $100,000 water bonds. G. S. Thompson, City Clk.

Renton, Wash.—Water works bonds to the amount of $4,500 have been sold, and the Council has adopted plans for a new system.

Sugar City, Colo.—The City Council has awarded to Holme & Allen, of Denver, the contract for a $20,000 water works system.

Pueblo, Colo.—The Colo. Fuel & Iron Co. is reported to be planning to irrigate over 10,000 acres of land adjacent to Pueblo; the proposed ditch to be 50 miles long and include many miles of 6 ft. wood pipe.

Alameda, Cal.—The Pure Water Co., principal place of business, Alameda, has been incorporated by M. French, H. H. Linnell, A. Linnell, A. J. Chamberlain, and others. Capital stock, $30,000.

Colorado Springs, Colo.—In a recent report relative to proposed improvements of Seven Lakes and the High Line reservoir, City Engr. E. W. Case estimates the cost of improvement at Seven Lakes, which include a tunnel through the Dead Lake divide and 2 reservoirs, at $15,000; in regard to the High Line reservoir, Mr. Case states that the Fairley site will sustain an 18,000,000 gal. reservoir, cost $13,000; and that the Brewer property can accommodate a 25,000,000 gal. reservoir, cost $20,000.

Platte, S. D.—Town Clk. W. F. McCall writes that the only bid received Nov. 17 for the construction of a system of water works was from the International Const. Co., of South Bend, Ind., at $6,750.

Fargo, N. D.—Deputy City Aud. N. C. Morgan writes that the question of either filtering the present water supply or securing a new supply is under consideration, but no action has as yet been taken.

Basalt, Colo.—City Clk. I. H. Mitchell writes that on Nov. 12 it was voted to construct water works at a cost of $11,000.

Salt Lake City, Utah.—Surveys have been started of the site of proposed reservoir in Parley's Canyon; the dam to be built across Parley's Creek will, it is estimated, form a reservoir which would store 1,000,000,000 gal. of water.

San Diego, Cal.—The Council has directed the City Engr. to prepare plans and estimates for an improved water system, cast-iron pipe to be used, the entire cost not to exceed $200,000.

Corona, Cal.—The Corona Power & Water Co. has been incorporated with a capital stock of $250,000, by T. P. Drinkwater, L. R. Curtiss, E. N. Currier, and others.

Los Angeles, Cal.—The Peck Ranch Water Co., principal place of business Los Angeles, has been incorporated with a capital stock of $15,000. Directors: H. T. Coffin, L. A. Pratt, N. Williams, and others.

Seattle, Wash.—Estimates for water mains have been filed as follows: Fourth Ave., south, $13,300; Laurel Shade Ave., $4,250; and Lee St., $1,400.

Canon City, Colo.—Arrangements are said to have been practically completed for a supply of water for this city, from artesian well south of Chandler, belonging to the Colorado Springs & Florence Oil Co., which is represented in Canon City by Augustus Macon and G. R. Gwillim.

Port Perry, Ont.—City Clk. W. H. Harris writes that on Jan. 1 the by-law providing for the construction of water works at a cost of $30,000 will be voted upon in this city.

Honolulu, H. I.—The San Francisco "Chronicle" states that a dam, capable of holding 2,560,000,000 gal. of water for irrigation purposes, is soon to be built across the Kaukonahua River, near the western end of this island. Estimated cost of dam, $250,000. The Waialua Agricultural Co. is said to be interested.

Sault Ste. Marie, Ont.—Press reports state that the Tagona Water & Light Co. will install a new pump of 6,000,000 gal. capacity.

St. John, N. B.—Water mains are to be extended, at a cost of $9,100. Wm. Murdoch, Supt. Water and Sewerage.

SEWERAGE AND SEWAGE DISPOSAL.

Portland, Me.—Bids are wanted at the Office of Constructing Quartermaster, Portland, until Dec. 27 for constructing a sewer system at Ft. McKinley, Great Diamond Island, as advertised in The Engineering Record.

Holyoke, Mass.—The Bd. of Pub. Wks. has voted to construct a 24-in. sewer, in Hampden St., 1,200 ft. in length.

Roselle Park, N. J.—Higginson & Shannon of Jersey City are stated to have received the contract for constructing a system of sewers for $44,441.

Syracuse, N. Y.—Local press reports state that the Bd. of Contract and Supply has rejected the only bid received, which amounted to $43,000, for the Teall Ave. sewer, and new bids will be asked.

Penn Yan, N. Y.—A vote will be taken on the proposition to expend $500 to have a competent engineer draw up plans and specifications for a complete sewerage system, his report to specify how the sewage can be disposed of.

Camden, N. J.—It is proposed to build sewers in numerous streets. Levi C. Farnham, City Engr.

Titusville, Pa.—Bids are wanted Dec. 1 for constructing a sewer in 1st St.; bids are also wanted at the same time for building a 12-in. tile sewer in Oak St. W. M. Dame, City Clk.

Lansdowne, Pa.—City Secy. H. L. Warren writes that on Nov. 5 it was voted to issue bonds as follows: $4,000 for sewers; $8,000 for paving, and $12,000 for sites for City Hall and engine house.

Albany, N. Y.—Bids are wanted Dec. 1 for the construction of a 15-in. vitrified stoneware pipe sewer in Livingston Ave. Isidore Wachsman, Clk. of the Bd. of Contract and Supply.

Harrisburg, Pa.—Bids are wanted Dec. 5 for the construction of 4 relief sewers. A. C. Stamm, Secy. Bd. of Pub. Wks.

Bloomfield, N. J.—The Sanitary Com. of the Bd. of Health of this city has been directed to confer with the Newark Bd. of Wks. with a view to having Newark join with Bloomfield in the construction of a sewer along Bloomfield Ave.

North Plainfield, N. J.—The Boro. Sewage Comn., B. A. Hegeman, Jr., Chmn., has made a preliminary report to the Council, in which 2 methods of sewage disposal are said to be practicable for this Boro., the first and most desirable being to carry sewage to tile water, the Com. was unprepared to report approximate cost of this system, still having the matter under investigation; the other method of sewage disposal was by the septic tank system, the total estimated cost of which would be approximately $87,400 for the plant, including mains, laterals and flush tanks, as planned by the Municipal Engineering Co. of New York City.

Patchogue, L. I., N. Y.—The construction of a sewerage system for the entire village is said to be under consideration.

Oneida, N. Y.—The Bd. of Pub. Wks. will on Dec. 2 receive separate bids for constructing 8-in. vitrified pipe sewers in West and Broad Sts., and for constructing a Portland cement concrete culvert on Higinbotham Brook at Main St. Address J. F. Connor, City Clk.

Norristown, Pa.—Bids are wanted Dec. 22 for constructing a sanitary sewer on Markley St. (diameter of pipe 18-in.), with necessary laterals, manholes, outfall cribbing and trestling. John H. Rex, Chmn. Sewer Com.; S. Cameron Corson, Boro. Engr.

Erie, Pa.—The Council has under consideration an ordinance providing for the construction of a main sewer on the line of Pennsylvania Ave., to cost $13,000.

New York, N. Y.—The lowest bid opened Nov. 25 by Boro. Pres. Jacob A. Cantor for an extension to outlet sewer at foot of W. 72d St. was from E. W. Robinson, at $26 per ft. for 371 lin. ft. of wooden barrel sewer 4 ft. interior diameter, Class I.; $16.40 per ft. for 79 ft. of brick sewer 4 ft. interior diameter, Class II.

Long Island City, N. Y.—The Bd. of Estimate and Apportionment, New York City, has adopted a resolution providing for amendments to the sewerage system in the 1st Ward.

Hoboken, N. J.—Local press reports state that Township Engr. Bond has completed plans and specifications for the outlet sewer and pumping station.

Buffalo, N. Y.—This city is to issue bonds to the extent of $100,000 to pay for the construction of a sewage pumping plant. Plans for same are being now made by the Bureau of Engineering.

Richmond, Va.—The Street Com. has recommended an immediate appropriation of $8,000 for the repair of the trunk sewer at 31st and Broad Sts.

The City Council has adopted a resolution asking that an additional $500 be appropriated in order to secure the services of Rudolph Hering, of New York City, as Consulting Engr. for the Atlanta sewer improvements.

Atlanta, Ga.—The Senate has passed the bill authorizing Atlanta to borrow $400,000 to extend the trunk sewers of the city.

Toledo, O.—Bids will be received Dec. 15 by Chas. H. Nauts, City Clk., for furnishing material and constructing a 15-in. circular pipe sewer, 8 and 10-in. inside diameter in portions of 4 alleys.

Akron, O.—Bids are wanted Dec. 2 for constructing a main trunk sewer in Dist. No. 4, also for a local sewer in Pearl St. Chas. H. Isbell, City Clk.

Milwaukee, Wis.—See "Water."

Chicago, Ill.—The Drainage Bd. has, according to local press reports, sold $1,500,000 drainage bonds.

Ottawa, Ill.—The City Council is considering the question of a sewerage system for the west side.

Bellefontaine, O.—According to local press reports the City Council may raise funds and construct a system of sewerage, purchasing a sewage farm and erecting a pumping station, without submitting the question to a vote of the people.

Kankakee, Ill.—The Council is said to be taking steps towards building lateral sewers.

Emmetsburg, Ia.—This city is said to be agitating the question of a sewerage system.

Crandon, Wis.—Press reports state that a sewerage system is to be constructed for this place.

Barberton, O.—The City Council has engaged J. E. Collins to prepare plans for sewers on Third and several other streets.

Chicago, Ill.—The Gage Park Improv. Asso. is in favor of the construction of a sewer in Western Ave. from 39th to 55th Sts.

Wabash, Ind.—Bids are wanted Dec. 22 for constructing sewers in Still and Miami Sts. John Hilty, City Engr.

New Orleans, La.—Bids are wanted by the Sewerage and Water Bd. until Feb. 2 for the construction of approximately 96 miles of sewers and appurtenances, of which 7 miles will be brick or concrete sewers, from 72 to 27-in. in diameter, laid from 10 to 24-ft. in depth, and 89 miles will be pipe sewers 36 to 8 in. in diameter, laid from 5 to 20 ft. in depth; with approximately 1,100 manholes and 450 flush tanks, as advertised in The Engineering Record.

St. Joseph, Mo.—According to press reports bonds to the amount of $200,000 will be issued next year for the purpose of extending main sewer and improving the electric light plant.

Topeka, Kan.—Plans have been prepared for the proposed Sewer Dist. east of the Santa Fe tracks. The sewer as planned will start with a brick main oval in shape, the greatest diameter being 80 in., subordinate mains will be 45 and 36 in. in diameter, with laterals 24 to 18 in. in diameter. Estimated cost, $80,000.

Enid, Okla. Ter.—This city has engaged Burns & McConnell, of Kansas City, Mo., to make surveys, and prepare plans and specifications for a system of sewerage.

Pasadena, Cal.—Local press reports state that bids have been asked for the construction of the outfall sewer to be 8,300 ft. long, a large part of which will have to be tunneled, for which $35,000 was voted.

Tacoma, Wash.—The City Council has adopted a resolution for the construction of sewers in several streets and alleys.

Lewiston, Idaho.—A correspondent writes that the new sewerage system comprising nearly 6 miles of pipe will be ready for bids about Jan. 1. Address Councilman C. A. Hastings, City Engr. Briggs or City Clk. Chas. McDonald.

Houston, Tex.—City Engr. Dormant has prepared plans and specifications for a tunnel sewer under Maury St. in the 5th Ward, estimated to cost $60,000.

Loveland, Colo.—The contract for constructing 10 000 ft. of sewer is reported to have been awarded to Dunigan & Palmer, of Shenandoah, Ia., for about $11,000.

Toronto, Ont.—In his recent report City Engr. Rust recommends, in regard to the Woodbine Ave. sewage disposal, that necessary disposal works for pumping and treating the sewage and the sewers proposed to be laid in the said district be constructed as a local improvement on the initiative principle. Estimated cost, $45,000.

BRIDGES.

Gloucester, Mass.—Preliminary steps are being taken looking to the erection of a $12,000 steel bridge over Gloucester Canal, to replace present wooden structure. W. L. Webber, City Engr.

Warehouse Point, Conn.—According to press reports surveyors are at work on Terry's Island planning for the construction of a bridge for the N. Y., N. H. & H. R. R., to have a double track, and cost about $1,000,000. Colon M. Ingersoll, Jr., Ch. Engr. of R. R., New Haven.

New Kensington, Pa.—A correspondent writes that an overhead bridge, 10 ft. wide and about 150 ft. long, may be built over the R. R.

New Castle, Pa.—See "Railroads."

Doylestown, Pa.—The Co. Comrs. are reported to have awarded the contract for building a bridge at Leatherman's Ford, in Bedminster Township, to Nelson & Buchanan Co., for $7,792.

New York, N. Y.—Bids are wanted Dec. 11 for furnishing the labor, materials and plant necessary for the construction of the tower foundation in the Boro. of Manhattan of the Manhattan Bridge No. 3, over East River, as advertised in The Engineering Record.

Coatesville, Pa.—The Pa. R. R. is reported to have awarded to John Goll & Co., of Philadelphia, the contract for a stone arch bridge to cross the west branch of the Brandywine at Coatesville; said bridge to be 54 ft. wide, to accommodate 4 tracks, and will consist of 9 semi-circular spans, 2 of which will be 86 ft. long, the others 78 ft. long each.

Harrisburg, Pa.—Contracts for the erection of 8 State bridges to take the place of bridges carried away by freshets last spring are reported to have been awarded by the Bd. of Pub. Buildings & Grounds as follows: Penn Bridge Co., Beaver Falls, bridge over Big Esquimaok Creek, Wayne Co., $34,889, and bridge over Sinking Creek, Centre Co., $6,847; W. H. Gulick, Phoenixville, bridge over Wallenpanyunk Creek, Wayne Co., $16,950; York Bridge Co., bridge over Wallenpanyunk Creek, $21,987, and Fisher's bridge, Columbia Co., $15,097; National Bridge Co., Pittsburg, bridge over Larry Creek, Lycoming Co., $17,900; King Bridge Co., Cleveland, Nuss bridge, Columbia Co., $22,750; Nelson & Buchanan, Chambersburg, bridge over Juniata River, Perry Co., $144,680.

Allegheny, Pa.—Local press reports state that a bridge is to be built across the Ohio from lower Allegheny to McKees Rocks; proposed length of bridge is said to be 300 ft., and cost about $300,000. John Murphy, Gen. Supt. of the Pittsburg Railways Co., is reported to be at the head of the incorporation which proposes to build the bridge.

Buffalo, N. Y.—Mayor Knight has approved the application of the Goodyear Co. to cross Hamburg turnpike with a canal and also to build and maintain a bridge over the canal.

Syracuse, N. Y.—Local press reports state that plans will be prepared by City Engr. Frank J. Schnauber, and contracts let so that work can be started early in the spring on the construction of 2 bridges—one over Onondaga Creek and the other over Oswego Creek.

Depew, N. Y.—The bridge on St. James St., over the B., N. D. & L. trolley line, is reported to have been condemned by the village authorities.

Jersey City, N. J.—Local press reports state that the wooden bridge over the Hackensack on the Newark Plankroad will soon have to be replaced by a steel bridge, at a probable cost of $250,000.

Reading, Pa.—Plans for approaches and superstructure for a $30,000 bridge, to be built on Front St. by the Reading Ry. and the United Traction Co. (S. D. Missimer, Ch. Engr., Reading), have been completed and are on file in City Engr. Murdoch's office; the superstructure is to be 1 span of 88 ft., and the south approach is to be 200 ft. long.

Pittsburg, Pa.—Local press reports state that all bridges on the Low Grade Div. of the Buffalo & Allegheny Valley Grand Div. of the Pennsylvania R. R. are to be strengthened and in some cases rebuilt, at an approximate cost of $800,000. There are in all about 12 2-span bridges from 75 to 80 ft. in length. Chas. P. MacArthur, Principal Asst. Engr., B. & A. Valley Div., Buffalo, N. Y.

Northeast, Md.—Asst. Treas. of the Co. Comrs. R. H. Logan, Elkton, Md., writes that at the Jan. meeting of the Bd. bids will be opened for the county bridge to be built over Northeast Creek at Northeast, at a cost of $6,000 to $8,000. W. D. Bratton, of Elkton, Engr. in Charge.

Bradford, Pa.—The Co. Comrs. may replace the bridge over the Tuns, which has a 106 ft. span, with a steel structure.

Cumberland, Md.—Bids will be received Jan. 5 by the Bd. of Co. Comrs for constructing the superstructure of several steel highway bridges. John N. Frantz, Clk.

Miami, Fla.—The Co. Comrs. are reported to have asked for bids for making approaches to the new steel bridge which is to be built over Miami River, at Avenue D; also for bids for the mason work.

Remington, Va.—Bids will be received Dec. 11 by John K. Taliaferro, Comr., for constructing 3 68-ft. steel spans, 1 stone abutment and 2 stone piers, fills on both sides of river, and raising the present spans 3 ft. higher with repairs to same.

Parkersburg, W. Va.—The Little Kanawha R. R., J. T. Blair, Pres., Parkersburg, and the Wabash R. R. Co., Jos. Ramsey, Jr., Pres., St. Louis, Mo., propose to build a suspension bridge across the Ohio from Parkersburg to Belpre; cost, $500,000.

Fowler, Ind.—Bids are wanted Dec. 2 by the Comrs. of Benton Co. for the construction of a bridge, 73-ft. span, 2¼ miles south and ½ mile west of Chase. Jas. D. Smyth, Aud.

Chippewa Falls, Wis.—Local press reports state that on Nov. 14 the railway bridge of the Omaha road extension over Yellow R., which has just been completed, was destroyed by floods.

Merrill, Wis.—Press reports state that the Council has unanimously voted to build a new bridge across Prairie River on 1st St.

Little Falls, Minn.—It is stated that at the recent election $5,000 bonds were voted to complete the Broadway bridge.

Reading, O.—The Co. Comrs., Cincinnati, have voted to issue $10,000 bonds to build a bridge over Mill Creek, between Reading and Lockland.

Milwaukee, Wis.—The Common Council Special Com. on the First Ave. viaduct on Nov. 20 received the repetition of an offer from Pres. John I. Beggs, of the St. Ry. Co., to pay the city $50,000 cash toward the erection of a new viaduct and a further offer in lieu thereof to pay the city an annual rental for use of viaduct equal to interest on $100,000 of the bonds sold to build structure. The rental will be paid yearly by the Co. until its franchise has run out in 1934. City Engr. Poetsch places the estimated cost of the viaduct at $550,000.

Milwaukee, Wis.—See "Water."

Cincinnati, O.—Bids are wanted by the County Comrs., Christian Bardes, Pres., until Dec. 13, for the purchase of Hamilton Co. bonds to the amount of $10,000, to be known as Clark and Davis St. bridge bonds.

Columbia City, Ind.—It is stated that bids are wanted Dec. 17 for constructing 9 steel bridges. Wm. H. Carter, Co. Aud.

Butler, Mo.—Bids are wanted Dec. 2 for constructing a steel bridge, 60 ft. long over Walnut Creek. R. E. Johnson, R. & B. Comr.

Walnut Springs, Tex.—Bids are wanted Dec. 3 for a steel bridge 2 miles southwest of Walnut Springs, bidders to submit plans. J. L. Mingus, Co. Clk., at Meridian, Tex.

Castroville, Tex.—The Co. Commissioners' Court, Hondo, Tex., is reported to have selected S. A. Oliver, of Houston, to prepare plans and supervise the construction of an iron wagon bridge across Medina River at Castroville.

Knoxville, Tenn.—The bridge which is proposed for the crossing of Clinch Ave. or some other avenue over the yards of the Knoxville, LaFollette & Jellico R. R., will, it is estimated, cost $60 000. A vote will be taken on the question of issuing $15,000 bonds, the city's portion of the cost of said bridge.

Harriman, Tenn.—The Cincinnati Southern R. R. is said to be arranging to build a steel viaduct over New River, in Scott Co., Tenn., near Harriman.

Beeville, Tex.—D. Troy, Clk. of Bee Co., writes that on Nov. 4 said county voted to issue $5,000 bonds for the construction of a bridge over Medio Creek.

Mendota, Mo.—It is reported that bids will be received Dec. 2 by Geo. W. Dickson, of Yuma, for a steel bridge.

Fairbury, Neb.—Bids are wanted Dec. 4 for constructing all bridges in Jefferson County for 1 year. W. S. Diller, Co. Clk.

Laurel, Mont.—The County bridge over the Yellowstone at Laurel, is said to be in an unsafe condition. Address Co. Comrs., Yellowstone, Mont.

Douglas, Wyo.—The Co. Comrs. have arranged for measuring and sounding North Platte River at Douglas, in order that plans may be prepared for a steel bridge to span the river at Center St.

Tacoma, Wash.—The City Council has passed a resolution providing for the construction of an iron bridge across the gulch adjacent to the city reservoir, to cost not more than $4,000.

San Francisco, Cal.—Stone Bros., of San Francisco, are reported to have secured the contract to build a $100,000 concrete bridge for the Salt Lake R. R.; the bridge is to be 800 ft. long and 80 6-ft. arches will be used in its construction; time for completion, 18 months.

Webster, S. D.—Bids will be received Jan. 7 by the Bd. of Co. Comrs. for constructing a 1-span steel bridge 24 ft. long and 18 ft. wide over Blue Dog Lake. Wm. Egeland, Co. Aud.

Caldwell, Idaho.—Edgar Meek, Clk. of the Bd. of Co. Comrs., writes that on Nov. 4 it was voted to build a bridge at Emmett St.

Georgetown, Colo.—It is stated that bids are wanted Dec. 30 for a steel bridge over Clear Creek. H. O. Walker, Co. Clk.

Sault Ste. Marie, Ont.—See "Railroads."

PAVING AND ROADMAKING.

Boston, Mass.—City Engr. Jackson estimates the cost of widening Atlantic Ave., without the construction of 2,100 ft. of sea wall as at first proposed, at $50,000 to $100,000; estimated cost with sea wall, $225,000.

Hartford, Conn.—Bids are wanted Dec. 10 for sheet asphalt paving, about 5,605 sq. yds., as advertised in The Engineering Record.

Lansdowne, Pa.—See "Sewerage and Sewage Disposal."

Long Island City, N. Y.—The Bd. of Estimate and Apportionment, New York City, has approved a resolution from the Local Bd. of Newtown, indorsing a petition to grade, curb and pave with asphalt St. Nicholas Ave. Estimated cost, $9,000.

Long Island City, N. Y.—Bids are wanted Dec. 4 by Boro Pres. Jos. Cassidy for grading, curbing and flagging Hamilton Ave.; the engineer's estimate calls for 24,500 sq. ft. of bluestone flagstone; also for grading, curbing, flagging and paving with asphalt on concrete foundation in Flushing and Davis Sts., engineer's estimate, 4,500 sq. yds. of asphalt and 6,000 sq. ft. of flagstone.

Buffalo, N. Y.—Comr. of Pub. Wks. Ward is in favor of the construction of a permanent stone (elevated) highway over Hamburg turnpike, for which he roughly estimates the cost would be $750,000, exclusive of the cost of pavement, which would be perhaps $100,000 additional; Col. Ward places the estimated cost of a highway built of stone abutments and steel superstructure at about $750,000, including the cost of pavement.

Bids are wanted Dec. 5 for paving Elam Pl., Richfield and Roberts Aves., and Ellicott St. Francis G. Ward, Comr., Dept of Pub. Wks.

Scranton, Pa.—Local press reports state that Dir. of Pub. Wks. Roche in preparing his estimates for the coming fiscal year has decided to ask the Councils for $50,000 to permanently improve a number of the city's unpaved streets and repair other streets.

Belair, Md.—Extensive highway improvements are in prospect for Harford County, surveys for some of the work having already been completed. A. N. Johnson is Highway Engr. of the Geological Survey.

Cortland, N. Y.—Cortland County Superv. have voted to build about 3 miles of good roads.

Canandaigua, N. Y.—Village Clk. Wm. E. Martin writes in regard to contemplated street improvements that there is under consideration a proposition for the appointment of a Bd. of Pub. Works; also a proposition to bond for general street paving, but nothing definite will be done before the annual election in Jan.

Somerville, N. J.—It is stated that contracts will be let Dec. 16 for the construction of macadam roads in Somerset Co. Wm. J. Logan, Dir.

Poughkeepsie, N. Y.—The Bd. of Co. Superv. has passed resolutions for the improvement of a road in the town of North East and for a road in Pawling. Plans and specifications have been received by said Bd. from the State Engr. for about 3½ miles of road in Hughsonville, estimated cost $28,050; also for over 3 miles of road (South Road) from Poughkeepsie city line to Casper Creek, estimated cost $30,400.

Niagara Falls, N. Y.—The Common Council has adopted a resolution providing for the paving of Niagara Ave. with bituminous macadam.

Brooklyn, N. Y.—Bids will be received Dec. 10 by J. Edw. Swanstrom, Boro. Pres., for improving portions of Bradford St., with 2,750 sq. yds. of trap block pavement, with sand joints and 6,400 sq. ft. of cement sidewalk; also for 11,860 sq. ft. of cement sidewalk on several other streets.

Allegheny, Pa.—The Council has passed an ordinance to submit to popular vote the proposal to increase the bonded debt $48,460 for the paving of Fleming Ave.

Jamestown, N. Y.—The Common Council has voted to pave a portion of Steele St. with brick at a cost of about $20,000.

East St. Louis, Ill.—Local press reports state that the Bd. of Local Improv. will soon let contracts for paving several streets in the eastern part of this city with vitrified brick.

Davenport, Ia.—City Engr. Murray has prepared estimates of the cost of paving a number of streets which it is proposed to improve next year.

Charleston, W. Va.—An ordinance is reported to have been passed providing for the issue of $70,000 street improvement bonds.

Cincinnati, O.—Bids are wanted Dec. 15 for improving a portion of Glen Parker Ave. by grading, setting curbs, flagging and macadamizing. Robt. Allison, Pres. Bd. of Pub. Service.

Minneapolis, Minn.—The City Council will ask the Legislature for authority to issue $700,000 municipal bonds; of this amount $500,000 is to be devoted to street improvements and $200,000 to grade schools.

Cleveland, O.—Local press reports state that Front St. is to be repaved in the spring.

Sioux City, Ia.—The approximate estimate of the cost of paving proposed for next spring as furnished by City Engr. is as follows: Nebraska St., 15,000 yds., asphalt, $35,000; Jackson St., 35,000 yds., probably with asphalt, $70,000; Sixth St., 6,000 yds., probably with brick, $12,000; W. 3d St., 25,000 yds., with either brick or asphalt, $60,000; total, $177,000.

Continental, O.—Bids are wanted Dec. 16 for the purchase of $13,500 street improvement bonds.

Kenosha, Wis.—H. S. Van Ingen, of 1323 Chamber of Commerce, Chicago, Ill., writes that it is proposed to construct the "Sheridan Drive" from Ill. State line to Kenosha; asphalt or macadam will be used; contracts will be let next year. Estimated cost, $500,000.

Fond du Lac, Wis.—The Council is said to be investigating the most desirable material for paving streets in this city.

Columbus, Ind.—Local press reports state that the City Council is receiving bids for the repair of asphalt pavements.

St. Paul, Minn.—It is stated that the Bd. of Pub. Wks. will soon let contracts for paving Nina and 9th Sts. with asphalt and Eagle St. with sandstone. Total cost to property owners, $75,000.

West Duluth, Minn.—A petition is being circulated asking the Council to pave 55th Ave.

Ft. Dodge, Ia.—Mayor S. J. Bennett writes that bids will be opened Dec. 17 for paving with Trinidad Lake asphalt. C. U. Reynolds, Engr. in Charge.

Galion, O.—Bids are wanted Dec. 19 for furnishing material and improving with brick portions of 2 alleys. J. O. Ross, City Clk.

Laporte, Ind.—Bids will be received Dec. 11 by the Bd. of Comrs. for constructing a series of macadamized roads in Center and Coolspring Townships, in all 6 4/10 miles. John R. Weaver, Chmn.

La Crosse, Wis.—Asst. City Engr. W. S. Woods writes that the Common Council has recommended for the coming year 58 blocks of granite top macadam, and 12 blocks of brick pavement. Bids for same to be received early next year.

Ann Arbor, Mich.—City Engr. Groves estimates that it will cost $32,000 to pave State St.

Bloomfield, Ind.—It is stated that bids are wanted Dec. 10 by the Comrs. of Geene Co. for the construction of gravel and macadamized roads.

Toledo, O.—Bids will be received Dec. 22 by Chas. H. Nauts, City Clk., for furnishing material and repaving portions of Erie St. and Avondale Ave. with block.

Birmingham, Ala.—City Engr. Julian Kendrick writes that ordinances are being prepared for about 25,000 cu. yds. of brick paving and 30,000 sq. yds. of asphalt paving.

Louisville, Ky.—The lowest bid received for asphalt paving on Peterson Ave. was from the Barber Asphalt Paving Co., at $1.48 per sq. yd.; total, $7,400.

New Orleans, La.—The City Council has adopted ordinances as follows: Directing the City Engr. to prepare plans and the Comptroller to let contracts for repaving a portion of St. Charles St.; directing the Comptroller let contracts for repaving Toulouse St.

Denver, Colo.—The Bd. of Pub. Wks. has recommended an ordinance creating a sidewalk district in southwest Denver. The estimated cost of the work is $54,600.

San Diego, Cal.—Bids will be received Dec. 4 by the Bd. of Pub. Wks. for paving with asphalt that portion of "Plaza" in block 42 known as Witherby St.

POWER PLANTS, GAS AND ELECTRICITY.

Brooklyn, N. Y.—Comr. R. G. Monroe, of the Dept. of Water Supply, Gas & Electricity, has issued an order to the effect that all telegraph, telephone and electric light companies in Brooklyn must place their wires underground at once. He also directed the Brooklyn Rapid Transit Co. to place underground its feed wires and all other wires except the trolley wires. The Commissioner has given the companies until May 1, 1903, to finish this work.

Niagara Falls, N. Y.—The Lower River Power Co. is stated to have petitioned the Bd. of Aldermen for a franchise.

Huntington, L. I., N. Y.—The contract for constructing the electric light plant for the Huntington Light & Power Co. is stated to have been awarded to Bunce & Holmes, of Huntington.

Jersey City, N. J.—The Montgomery Light & Water Power Co. has been incorporated; capital, $2,000,000. Incorporators: Chas. N. King, W. Mondo Green and Saml. E. Renner. Office of company, 243 Washington St.

Reading, Pa.—Rudolph Meiehling is stated to have been selected to make an estimate of the cost of constructing and maintaining an electric light plant.

Sellersville, Pa.—The Boro. Council is reported to be considering the advisability of establishing an electric light plant.

Erie, Pa.—The Edison Electric Light & Power Co. is stated to have secured the contract for lighting the city for 5 years at 16 cts. per lamp per night for enclosed lamps.

Brooklyn, N. Y.—Bids were opened Nov. 25 by Homer Folks, Comr. Pub. Charities, Ft. of E. 26th St., N. Y., for installing a heating and power plant, Kings Co. Buildings, as follows: Thos. G. Carlin, 215 Montague St., $49,133; James Curran Mfg. Co., $56,500; E. Rutzler, $58,000; United Heating Co., $58,220; Blake & Williams, $61,964; Donnelly & Merritt, $67,500.

Bids were opened at the same time for the installation of an electric lighting plant, Kings Co. Buildings, as follows: Peet, McAnerny & Powers, 225 4th Ave., N. Y., $20,179 (bid protested on acct. of insufficient security); Frank G. Blanchard, 45 Willoughby St., $20,469; Weiderman & Conklin, $20,530; United Engineering & Contr. Co., $21,000; Western Electric Co., $22,097; A. D. Granger Co., $26,698.

New York, N. Y.—Plans have been filed for a 3-story brick gas retort house, 109x115 ft., to be erected by the Central Union Gas Co., 138th St. and East River. Architect, Louis Brown, 40 Cedar St.

West Seneca, N. Y.—The General Electric Co., of Buffalo, N. Y., has secured the contract for lighting the town at $75 per light per year.

Summit, N. J.—See "Water."

Philadelphia, Pa.—Only one bid for electric street lighting for next year was received at the Dept. of Pub. Safety Nov. 24. It was from the Brush Electric Light Co., the prices being the same as those paid to it for the present year. The whole number of electric lights to be provided for is 9,284, which were maintained this year at a cost of $1,009,358. Prices per light per night for arc lights range from 28 to 35 cts.

Middletown, N. Y.—T. E. McGarr, Secy. State Comn. in Lunacy, Albany, writes that the contract for electric wiring and fixtures for Pavilions Nos. 1 and 2, Middletown State Hospital (bids opened Nov. 19), has been awarded to F. L. Frost, of Albany, for $5,409.

Philadelphia, Pa.—Bids are wanted Dec. 6 for erecting a gas holder, with 75,000 cu. ft. capacity in steel tank. John V. Shoemaker, Pres. Dept. of Charities and Correction.

Norristown, Pa.—A press report states that the United Power & Transportation Co. contemplates erecting here in the spring a power plant, to cost $150,000.

Baltimore, Md.—Robt. J. McCuen, Supt. Lamps & Lighting, writes that the following bids were opened Nov. 5 for installing and maintaining naphtha street lamps for a term of years; prices are per lamp per year, for 1, 2, 3 and 5 years respectively: American Lighting Co., Baltimore, $23.45, $23.45, $23.45, $23.45; Union Lighting Co., Washington, D. C., $24.40, $24.95, $25.85, $26.35; Welsbach St. Lighting Co. of Amer., Philadelphia, Pa., $29.50, $29.50, $29.00, $28.50. The contract was awarded Nov. 15 to American Lighting Co., term of 3 years; no minimum number of lamps stated in specification, but there are 1,068 naphtha lamps in service at present time. The contract for 200 c. p. gasoline lamps was awarded at the same time to the Wellington Lighting Co. for 1 year, at $49.89 per lamp per year.

Richmond, Va.—Supt. Knowles in a report to Council, Nov. 18, recommends the construction of a new gas tank or holder, and estimates the cost, with a capacity of 2,000,000 ft., at $200,000.

Michigan City, Ind.—City Clk. Edw. J. Heise writes that the City Council has awarded the contract for all-night lighting of the city with 125 electric arc lamps of 2,000 nominal c. p. to the Michigan City Electric Co., of Michigan City, at $75 per lamp per annum.

Albion, Mich.—Chas. B. Kelsey, of Grand Rapids, Mich., Pres. of the Albion Gas Co., writes that said company contemplates installing next spring a new holder with a capacity of from 40,000 to 50,000 cu. ft. Local Mgr., Richard Schadellee, Albion.

Muncie, Ind.—City Clk. R. G. Kickok writes that M. J. McGuff, C. M. C. Shanks and E. B. Steck are the Com. of Council in charge of proposed improvements to city electric light plant. W. M. Warner, Supt.

Colfax, Wis.—The Town Clk. writes that the municipal electric light plant is to be rebuilt, at a cost of $1,500. C. I. Anderson, Engr. in Charge.

Glidden, Ia.—City Clk. pro tem. H. W. Porter writes that is is proposed to construct a gas plant, but nothing definite has as yet been done. G. W. McNaught, Engr. in Charge.

Odell, Ill.—The Odell Electric Co., of Odell, has been incorporated, to furnish light, heat and power; capital, $5,100. Incorporators: W. M., Anna K. and Wm. N. Buchanan.

Columbus, Ind.—The City Council is reported to have ordered the purchase and installation of a new 150-lamp street electric light plant.

Indianapolis, Ind.—Saml. Shutt, Ch. Engr. of the State House, is stated to have reported to Governor Durbin that the cost of a power plant and electrical equipment for the Capitol would be about $150,000. The next Legislature will probably be asked to appropriate this amount.

Milwaukee, Wis.—See "Water."

Holly, Mich.—The Holly Electric Light & Power Co. has been incorporated, with a capital of $10,000.

Kansas City, Mo.—See "Water."

Madisonville, Ky.—The City Council is reported to be considering the question of constructing an electric light plant, and have asked Mr. Hite, Mgr. of the Henderson Electric Light Plant, to make a survey.

Walnut Ridge, Ark.—See "Electric Railways."

St. Joseph, Mo.—See "Sewerage and Sewage Disposal."

Lead, S. D.—The City Council is stated to have granted the Practical Gas Co. a franchise to construct a gas plant.

Canon City, Colo.—Dr. Bell, of Pueblo, is reported interested in the construction of a gas plant at Canon City.

Albuquerque, N. M.—The Albuquerque Gas, Electric Light & Power Co. has been incorporated, with a capital of $200,000, by Wm. S. Iliff, Maynard Gunsul, Wm. B. Childers and others.

Omaha, Neb.—A. Rosewater is stated to have petitioned the Council for permission to string wires along the streets and build conduits for the transmission of power from the proposed Platte River Canal.

Salt Lake City, Utah.—The Dirs. of the Utah Sugar Co. are reported to be planning to construct a power plant on the Bear River, to furnish power to the new sugar factory, and furnish electric light to other institutions in the Bear River Country.

Sterling, Colo.—Town Clk. C. L. Goodwin writes that on Nov. 18 it was voted to grant a franchise for an electric light plant to O. P. Sells, of Denver.

Minnedosa, Man.—The Council is stated to have granted E. S. Harrison, of Winnipeg, a franchise for an electric light plant.

San Juan, Porto Rico.—Wm. Yeager, representing the Vandegrift Construction Co., Drexel Bldg., Philadelphia, Pa., is stated to have applied to the Executive Council for a franchise to develop the water power and construct an electric railway from San Juan to Ponce.

ELECTRIC RAILWAYS.

Concord, N. H.—The Concord, Dover & Rochester St. Ry. Co. is reported to be surveying for the construction of a line between Dover and Concord, a distance of about 39 miles.

Pittsfield, Mass.—The Dirs. of the Pittsfield St. Ry. Co. are stated to have petitioned for new locations on 10 streets of the city. F. E. Eckerson, Ch. Engr., Pittsfield.

Hartford, Conn.—Thos. G. Perkins is reported interested in the construction of an electric railway between Hartford and Middletown.

Bangor, Me.—The Pushaw Lake Ry. Co. has been incorporated, with a capital of $50,000, to construct and operate a railway from some point on the Penobscot Central Ry. in Bangor, to Pushaw Lake in the town of Glenburn. F. O. Beal, Pres., and E. C. Ryder, Secy., both of Bangor.

Seymour, Conn.—The Connecticut Ry. & Lighting Co. is reported to be making arrangements for the extension of its lines up the Naugatuck Valley to Seymour. J. E. Sewell, Gen. Mgr., Bridgeport.

Brockport, N. Y.—The Village Trus. are stated to have granted a franchise to the Albion Ry. Co.

Syracuse, N. Y.—The Syracuse Rapid Transit Co. is stated to have secured a franchise through the town of Clay. E. G. Connette, Gen. Mgr., Syracuse.

Birdsboro, Pa.—The United Traction Co. is stated to have petitioned the Town Council for a franchise to extend the Black Bear line into the borough.

Pittsburg, Pa.—Charters have been granted to the Bloomfield St. Ry. Co., with a capital of $80,000, to build a line 1 6/10 miles long in Pittsburg, commencing at the intersection of 14th St. and Liberty Ave., and running along Liberty Ave. to Denny St., Lawrenceville; also to the Second Ave. Ry. Co. to construct a line 4 8/10 miles long, beginning at the intersection of Grant St. and 2d Ave., and along 2d Ave. to the line of the Glenwood high bridge, returning by the same route; this company has a capital of $240,000. Incorporators of both companies are: A. P. Weitel, Allegheny; W. O. Anderson, Wilkinsburg, and W. Douglass, of Pittsburg.

Northeast, Md.—The Cherry Hill, Elkton & Chesapeake City Electric Ry. Co. is stated to have petitioned for a right of way through Northeast.

New York, N. Y.—The Brooklyn Rapid Transit Co. has awarded the contract for materials for 4 new loops at Manhattan end of Bklyn. Bridge to the American Bridge Co., and the contract for erection to the Eastern Construction Co., 52 Classon Ave., Brooklyn.

Buffalo, N. Y.—A. E. Leon, of Boston, Mass., is reported to have purchased the Buffalo, Hamburg & Aurora Ry. It is stated that the road will be extended to Aurora and improvements made along the line.

High Point, N. C.—E. D. Steele, of High Point, is reported interested in the construction of an electric railway to connect High Point, Winston, Salem and Greensboro.

Cincinnati, O.—The Cincinnati, Richmond & Muncie Ry. Co. is reported to be making surveys for a new line between Cincinnati and Louisville that will shorten the distance between these two cities to 105 miles.

Troy, O.—The Miami Co. Comrs. are stated to have granted a franchise to the Dayton & Kenton Traction Co. R. E. Kline, Ch. Engr., Dayton.

Marysville, O.—The Toledo, Columbus, Springfield & Cincinnati Electric Ry., through M. B. Earnhart, of Columbus, is stated to have petitioned the Council for a franchise through this city. It proposes constructing a line from Toledo to Columbus, by way of Lima, Bellefontaine and Columbus.

New Albany, Ind.—The City Council is stated to have granted a franchise to the New Albany, Paoli & French Lick Traction Co.

Terre Haute, Ind.—The Co. Comrs. are stated to have granted the Terre Haute St. Ry. Co. permission to use the highway from the city limits to the county line for its proposed interurban line to Clinton.

Elwood, Ind.—The City Council is stated to have granted the Union Traction Co. a franchise on S. 28th St. for the extension of its line to the tin-plate works. W. H. Bloss, Ch. Engr., Anderson.

North Chicago, Ill.—The Village Bd. is stated to have granted a franchise to the Chicago & Milwaukee Electric Ry. Co. B. B. Blyth, Ch. Engr., Highwood, Ill.

Middlefield, O.—The Co. Comrs. are stated to have granted F. B. Morgan a franchise for an electric railway from Middlefield to the State line near Sharon.

Grand Rapids, Mich.—A company is reported organized here, with a capital of $2,500,000, to construct an electric railway from Grand Rapids to Charlotte, Battle Creek and Lansing. Wm. A. Smith and Thos. Hefferan, of Grand Rapids, are among the incorporators.

New Castle, Ind.—The New Castle & Muncie Traction Co. has been incorporated, with a capital of $10,000, to construct a line through the towns of Mt. Summit, Springport, Oakville, Cowan, Cambridge City, Knightstown, Dunreith and Connersville. Incorporators: Ezekiel T. Ice, Mt. Summit; Frank W. Nixon and Clay C. Hunt, New Castle, and others.

Evansville, Ind.—The Vanderburg Co. Comrs. are stated to have granted a right of way to the Evansville, Boonville & Rockport Electric Ry. Co.

Green Bay, Wis.—The East Wisconsin Traction Co. has been incorporated, with a capital of $50,000, to construct and operate a street railway in the cities of Green Bay, Depere, Two Rivers and Manitowoc, and in the Counties of Brown and Manitowoc. Incorporators: Wm. F. Paul, Danfort M. Maxey and Chester D. Cleveland, Jr.

Elizabethtown, Ky.—T. S. Gardner, of Hardin, is reported interested in the construction of an electric railway from Elizabethtown to Bowling Green, via Leitchfield.

Louisville, Ky.—It is stated that the Louisville Ry. Co. will construct an extension of about a mile on its E. Chestnut and Barrett Ave. line. F. M. Miller, Ch. Engr., Louisville.

It is stated that the Falls City Belt Line Ry. Co. is about to petition for a franchise to construct a belt line. Saml. Bowman, Pres.

Shelbyville, Ky.—The Louisville Anchorage & Pewée Valley Ry. Co. has petitioned the Council for a franchise. It proposes extending its line from Lakeland through Middletown and Simpsonville, along the State pike to Shelbyville. P. Moore, Mgr., Louisville.

Walnut Ridge, Ark.—S. C. Dowell and S. Riegler, of Walnut Ridge, are reported interested in the construction of an electric railway between Walnut Ridge and Hosie, and electric light plants at both places.

Natchez, Miss.—It is stated that the Natchez Electric St. Ry. Co. will extend its line south of Main St. to Homochitto St. E. H. Jackson, Mgr., Natchez.

Omaha, Neb.—The Bd. of Pub. Wks. is stated to have granted the Omaha St. Ry. Co. permission to construct a double track railway on 24th, Fort and 30th Sts. W. A. Smith, Mgr., Omaha.

The Omaha, Decatur & Northern Ry. Co is reported organized to construct an electric railway from Omaha to Decatur, Neb. F. W. Bennett, of Bennett & Co., of Toledo, O., is reported to be one of the promoters.

Quincy, Col.—H. H. Yard and A. Ekman, of Aroville, are reported interested in the construction of an electric railway up the North Fork and East Branch, to connect with several mineral locations along these streams.

Bakersfield, Cal.—A press report states that surveys have been completed for the construction of an electric railway from Ventura to Sunset and Bakersfield, a distance of about 165 miles, for the Bakersfield & Ventura Ry. Co. Maj. H. M. Russell, of Los Angeles, is reported interested.

Emeryville, Cal.—The Town Trus. are stated to have granted a franchise to the San Francisco & San Jose Electric Ry. Co.

North Yakima, Wash.—The City Council is stated to have granted a franchise to the Yakima Valley Central Ry. Co.

San Juan, Porto Rico.—See "Power Plants, Gas and Electricity."

Monterey, Mexico.—Sperry, Jones & Co., of Baltimore, Md., are stated to have purchased 2 mule lines, about 30 miles in length, in Monterey and will convert same into electric lines.

RAILROADS.

Buffalo, N. Y.—The State Ry. Comn. is stated to have granted the Buffalo & Susquehanna R. R. Co. permission to construct its line. The new line will be 84 miles in length, connecting Buffalo with the Buffalo & Susquehanna R. R. at Wellsville, N. Y.

Philadelphia, Pa.—Both branches of City Council on Nov. 20 adopted the resolution requesting the Finance Com. to report a bill authorizing a loan of $8,500,000 to abolish grade crossings.

Donora, Pa.—A press report states that the Union Steel Co., of Donora, will construct a railroad from Donora, via South Sharon, to Elk Creek Harbor.

New York, N. Y.—The State R. R. Comrs. on Nov. 24 granted the application of the Pennsylvania, New York & Long Island R. R. Co. to construct a tunnel railroad in this city to connect the Pennsylvania and the Long Island Railroads.

New Castle, Pa.—A press report states that a tunnel will be constructed by the Pittsburg, Lisbon & Western Ry. in effecting an entrance to this city. The tunnel will extend underneath the rocky cliffs of Taylor Township, on the west side of the city and will be driven through a bed of rock for about ⅛ of a mile. Emerging from its mouth the road makes a curve and crosses Shenango River on a $50,000 viaduct that is planned. R. W. Billingsley, Supt., Lisbon, O.

Chicago, Ill.—The Chicago Junction R. R. Co. has been incorporated, with a capital of $50,000, to construct a railroad from a point in the city of Chicago to a point in connection with the South Side Elevated R. R. Co. and other railroads in Cook County. Incorporators: Fredk. R. Babcock, Wm. Raymond and others.

Jasper, Ind.—The Southern Ry. Co. is reported to have decided to construct an extension from Jasper to French Lick Springs, a distance of about 28 miles. C. H. Ackert, Gen. Mgr., Washington, D. C.

Amarillo, Tex.—The Choctaw, Oklahoma & Texas R. R. Co. is reported to have filed an amendment to its charter with the Secy. of State, providing for the immediate extension of that road west from Amarillo, Tex., to Tecumsari, N. M., a distance of about 125 miles, where connection will be made with the Rock Island, El Paso line. S. H. Madden, Vice-Pres., Amarillo.

Burnsville, W. Va.—A press report states that the contract, amounting to $2,500,000, was awarded on Nov. 25 by Jos. Ramsey, Jr., of St. Louis, Mo., Pres. of the Wabash R. R., and J. T. Blair, of Parkersburg, W. Va., Pres. of the Little Kanawha R. R., for 71 miles of line to connect part of the Little Kanawha and the West Virginia Central. Clemens & Co., of Philadelphia, Pa., and J. Henry Miller, of Baltimore, Md., secured the contracts. The line will run from Sandy Bend to Burnsville, W. Va., from which point it will connect with the West Virginia Central at Bellington. Contracts for the remainder of the road, 118 miles, will be let before Feb 1.

Inez, Ky.—The Wolf Creek Ry. Co., of Martin County, is reported incorporated, with a capital of $200,000, to construct a railroad from the mouth of Wolf Creek, a distance of about 20 miles.

Springfield, Mo.—The Missouri Pacific Ry. Co., through Russell Harding, Gen. Mgr., is reported to have submitted a proposition to the citizens of Springfield to build a north and south railroad from Bagnelle to Memphis in consideration of a right of way through Green County and depot grounds. The proposition is reported to have been accepted. H. Rohwer, Ch. Engr., St. Louis.

Dossetts, Tenn.—It is stated that the Knoxville, Lafollette & Jellico R. R. Co. will construct the Oliver Springs & Coal Creek branch from Dossetts into the coal fields of East Tennessee.

Durango, Mexico.—It is stated that Ch. Engr. R. B. Gosuch, of the Mexican International R. R., estimates the cost of constructing an extension of that road from Durango to the Port of Mazatlan, on the Pacific coast, at $17,000,000. The proposed line will cross the Sierra Madras. New York, N. Y., office is 25 Broad St.

Ft. William, Ont.—The Canadian Northern Ry. Co. is reported to have sent out surveying parties from Ft. William to locate a route from there to White River, where the proposed extension easterly from Ft. William will meet the Algoma Central. D. B. Hanna, Gen. Supt., Winnipeg, Man.

Gravenhurst, Ont.—A press report states that the Grand Trunk Ry. is reported interested in the construction of a railroad about 3,000 miles in length, which will cost about $75,000,000. The new railroad will run through a portion of northern Ontario known as New Ontario, starting from North Bay or Gravenhurst, Ont., and extending through Manitoba, the Northwest Territories and British Columbia to Bute Inlet, or Port Simpson, B. C. Chas. M. Hays, Gen. Mgr., Montreal, Que.

Sault Ste. Marie, Ont.—Bids are wanted Dec. 15 by the Manitoulin & North Shore Ry. Co. for grading and bridging, Section 1, between Meaford and Tobermory; Section 2, between Fitz William Island and Gertrude mines, and Section 3, between Gertrude mines and Sault Ste. Marie. W. Z. Earle, Ch. Engr.

PUBLIC BUILDINGS.

New York, N. Y.—Bids are wanted Dec. 4 by the Dept. of Correction, Thos. W. Hynes, Comr., for furnishing all labor and material required for bath tubs, water closets, lavatories, etc.

The lowest bidder Nov. 24 for alterations and additions to electric light wiring in Bellevue Hospital, 26th St. and 1st Ave., was T. F. Jackson, 592 Columbus Ave., his bid being $6,249.

Kingston, N. Y.—Bids are wanted Dec. 1 for the erection of a building for Kingston City library; plumbing and electrical work to be bid on separately. John J. Linson, Chmn. Bldg. Com.

NEW INDUSTRIAL PLANTS.

The Eureka Bending Works, East Berlin, Pa., will erect a 3-story, 50x100-ft factory at York, Pa., and are in the market for a 75 to 100-H.-P. engine and a rim bending and spoke machine.

The Warren, O., Sheet Metal Co. has begun the erection of a 42x108-ft. factory and will add other buildings in the spring. The company is in the market for boiler, engine and equipment for making galvanized sheet metal pails, coal hods, tubs, etc.

The Carter-Crume Co., Ltd., Niagara Falls, N. Y., makers of cash sales books, is erecting a 426x290-ft. factory, which it is contemplated to run by electricity; nothing definite, however, has been decided regarding the power.

G. A. Blesch, Menominee, Mich., is interested in the erection of a beet-sugar plant. A 600-ton plant with facilities for increasing to 800 tons is being considered.

Kane & Roach, Niagara & Shonnard Sts., Syracuse, N. Y., makers of carriage and wagon and other special machinery, expect to build an addition of about 60x80-ft. to their plant, to be equipped with a 20-ton traveling crane.

The Diana Brick & Tile Co., Ltd., Beaumont, Tex., which is erecting a plant to having a daily capacity of 100,000 brick, machinery for which has been purchased, expects to add a dry pressed plant for making face brick.

J. W. Kilgour & Bro., Beauharnois, P. Q., Can., will rebuild their recently burned furniture factory. The power plant was saved, and will be used again.

The Quaker Portland Cement Co., 26 Broadway, New York, will erect at Sandts Eddy, Pa., a cement mill, to have a daily capacity of 4,000 bbls. The company desires correspondence regarding labor-saving devices and improved machinery.

The Liberty Brewing Co., Springfield, Mass., will erect a plant to have a storage capacity of 20,000 bbls., and is in the market for an engine of about 200-H.-P.

The Washington, Pa., Chemical Mfg. & Supply Co. is erecting a 120x150-ft. building, and will require a 25-H.-P. gas engine. The company will equip a testing laboratory.

The A. & F. Brown Co., Elizabethport, N. J., founders and machinists, are extending their foundry, which, when completed, will be 181x85 ft., and intend to erect a 200x80-ft. fireproof building, each to be equipped with a 20-ton electric traveling crane. The machine shop will be erected in the spring.

J. J. Franey, Shenandoah, Pa., will erect a 55x175-ft. building of about 8 stories, to contain a 25,000-bbl brewery with a 20-ton ice plant and an electric light plant having 250 arc and 25,000 incandescent lights, a silk knitting mill and other industries.

BUSINESS NOTES.

The York, Pa., Mfg. Co. reports the following among recent orders: Cook & Atchley, Trenton, N. J., 15-ton ice plant; R. Greene, Greenville, N. C., 10-ton ice plant; Flat Top Ice & Cold Storage Co., North Fork, W. Va., 15-ton ice plant; Dover Brewing Co., Canal Dover, O., 30-ton ice plant; Queen City Ice & Cold Storage Co., East St. Louis, Ill., ice machinery; Heckle & Kellogg, Cape Charles, Va., 15-ton ice plant; D. J. Crowley, Georgetown, S. C., 25-ton ice-making machine and 10-ton freezing and distilling outfit; Augusta, Ga., Brewing Co., 50-ton brine tank and coils; Beare Bros., Humboldt, Tenn., 15-ton freezing and distilling plant; West Virginia Brewing Co., Huntingdon, W. Va., direct expansion piping for addition and re-piping of old storage room; Bee Hive Hygeia Ice Co., Brooklyn, N. Y., 25-ton plate freezing plant.

Hales & Ballinger, s. w. corner 12th and Chestnut Sts., Philadelphia, architects and engineers, have awarded a contract to Edward Fay, Philadelphia, for a 2-story, 50x180-ft. factory building of slow-burning construction for the Lester, Pa., Piano Co. They have also awarded a contract to Kaighn & Draper, Camden, N. J., for a 4-story, 30x100-ft. addition to the plant of the Victory Talking Machine Co., Camden.

The Ball Engine Co., Erie, Pa., reports the following among recent orders: Chartier Brewing Co., Carnegie, Pa., an engine direct-connected to a 30-Kw. Westinghouse generator; Northern Electric Mfg. Co., Madison, Wis., a 125-H.-P. engine direct-connected to a 75-Kw. Northern generator; City of Fayetteville, N. C., 125-H.-P. engine for electric plant.

The district office managera of the Westinghouse Electric & Mfg. Co., representing all the principal cities of the United States, spent the week ending Nov. 22 in their usual annual visit to the works and offices of that company at East Pittsburg.

The New York office of the Harrisburg Foundry & Machine Works at 203 Broadway, which was formerly under the management of W. P. Mackenzie, will be conducted by the firm of Mackenzie & Quarrier.

THE ENGINEERING RECORD.

Volume XLVI., Number 23.

TABLE OF LEADING ARTICLES.

Some Features of the Discharge of Large Pipes. 529
The Boiler Shops of the Babcock & Wilcox Company. (Illustrated) 529
Floor Construction and Fireproofing in the Government Printing Office, Washington, D. C. (Illustrated) 535
The Practical Operation of Sewage Purification Works. (Illustrated) 537
An Analysis of the Commercial Value of a Water-Power. (Illustrated) 540
Rockwood Compound Engines........................ 542
Water Supply for the Ansonia Swimming Bath. (Illustrated) 543
The Annual Meeting of the American Society of Mechanical Engineers 545

The Engineering Record is published every Saturday at 21 Park Row, New York. Its opinions on technical subjects are either prepared or revised by specialists.

Subscriptions are received and single copies supplied by the International News Company, Breams Building, Chancery Lane, London.

The subscription rate is $5 a year for the United States, Canada and Mexico, and $6 for other countries in the Postal Union. Remittances should be made by check, New York draft or money order in favor of The Engineering Record. No responsibility is assumed for payments made otherwise, except those for subscriptions to the International News Company.

Some Features of the Discharge of Large Pipes.

Although some excellent work has been done in the measurement of the discharge of pipe lines of large diameter during the past eight or ten years to say nothing of the work done prior to that time, there remains still to be ascertained considerable information not only of interest to engineers but bearing directly upon the volume of discharge for a given diameter and hydraulic gradient. It was but a comparatively short time ago that the effect of the rivet heads of a riveted steel pipe on its discharge was brought to the attention of civil engineers in a very forcible manner. It has been established beyond question that the presence of the rivet heads and of the unavoidable joints in such a pipe has far too great a resisting effect upon the flow of the water to be neglected; at the same time much yet remains to be determined by actual test before tne elements of the problem as a general one can be considered established in a complete and quantitative way. Indeed it is an open question whether such resistances as those alluded to in a riveted steel pipe result from actually obstructive effects to the velocity parallel to the axis of the pipe, or whether the result is due to the deflection of the molecules of the water in a direction more or less nearly at right angles to that axis, thus producing eddies and checking the progressive general motion of flow. In reality that question may arise in connection with a considerable class of similar resistances, and there is practically little or no definite information available on which to base a reply.

The principles on which the standard treatment of sudden contraction or enlargement of the flow of a limited or enclosed stream of water is based are of course familiar to every student in hydraulics, but the conditions of the actual problem as it occurs in large pipes are so different from those assumed in the text book analysis that a vast amount of investigation of the circumstances under which water moves through a pipe is imperatively needed before anything like an exact knowledge of this class of resistances can be acquired.

It is perfectly well known by every civil engineer who has had any sensible amount of hydraulic experience that the progressive motion of water in any closed pipe or open channel is but one element of probably the most complicated mass of motions found in nature. Although the flow of water in such channels and in accordance with "the principle of continuity" is assumed to be a case of parallel motions not even the roughest approximation to that condition of things is ever found within the limits of velocity in which water moves in connection with any engineering work. It is a little singular therefore that in all the current meter observations which have been made in large pipes and open conduits this feature of the flow has not received more experimental attention, especially as it cannot fail to affect materially the discharge. It would be interesting if not of immediate practical importance to ascertain the disturbing effect of this character of rivet heads and plate joints in a closed steel pipe as compared with similar eddying motions or velocities in open channels with comparatively smooth sides and bottom like those of large conduits. It is altogether probable, if not certain, that the flow would be far less disturbed in the latter class of channels than in the former, but the hydraulics of discharge would gain materially in its quantitative features with the attainment of exact information in this direction.

An excellent paper on "The Flow of Water in Wood Pipes" in the August number of the Proceedings of the American Society of Civil Engineers by Mr. Theron A. Noble, M. Am. Soc. C. E., not only suggests in its reading the inquiries which have been outlined above, by the current meter observations which he made in his 54-inch stave pipe, but also other features of discharge which are likely to occur in a pipe line of larger diameter subject to distortion. As usual the meter was used to determine only those components of velocity parallel to the axis of the pipe. The interior of a well made stave pipe is so smooth that the exciting causes of eddying cross-currents are probably reduced nearly to a minimum, yet they exist to some extent. It would add much to the technical value of such careful and extended investigation in the actual discharges of large conduits to make the velocity observations complete and it would add little either to the cost or the time required to attain that end. The considerable variations in the coefficients of Chezy's and other formulas observed at different times for the same class of pipe, and in the same condition, and for essentially the same velocities might receive much illumination if these experimental observations were completed in the manner indicated.

Mr. Noble, in the paper already cited, gives among other things the results of a large number of measurements of the interior diameters of the 54 and 44-inch pipes with which he experimented and they indicate marked distortion of shape, so much so in fact that the average cross-section employed by him was elliptic in outline rather than circular. The influence of this distortion, which, of course, was widely varying in different points of the line, was probably not much, and yet it is scarcely safe to ignore an effect of that kind without the possession of positive data justifying such a course. It is practically certain that the failure to recognize distortion in shape like that occurring in the curves of a line of fire hose, has led to serious errors in conclusion in at least one or two prominent instances. There can be little doubt of the fact that the adjustment of the conditions of flow in such flexible pipes have eliminated in some cases the resistance characteristic of sharp curves.

The plotted results of Mr. Noble's tests reveal one important and interesting relation in which it is shown that according to his experiments the velocity head throughout a considerable range of velocities was found directly proportionable to the friction head in the pipes. There is nothing new in this relation and yet it is an interesting as well as important confirmation of some of the fundamental concepts in practical hydraulics. There may, however, be some doubt as to the advisability of the general formula largely empirical which he proposes for the velocity of flow in circular pipes. The whole field of empirical formulas for such purposes has been pretty well worked over and if a new one is to be discovered it must certainly be based on a much wider range of experimental determinations than those connected with the Seattle stave pipe line.

The Boiler Shops of the Babcock & Wilcox Company.

For many years a certain part of the Bayonne shore of the Kill von Kuil, as the busy channel that separates northern Staten Island from New Jersey is called, has been occupied by a number of handsome residences with lawns and shade trees separating them from the river bank. To the east of this property the water front has been built up by manufacturing enterprises of one kind or another attracted by the excellent shipping facilities that the location offers. About three years ago the Babcock & Wilcox Company had for some 25 years been manufacturing water-tube boilers at their shops at Elizabethport, N. J. Finding the conditions there made impossible the enlargement that their increasing business demanded, investigation discovered the advantages of the property on the shore of the Kill von Kull at Bayonne, and there a tract of partly unimproved land was purchased. The property has a water front of some 900 feet, extends backward about 2,000 feet from the water and includes several residential sites. Quite a little filling and grading was done, after which the construction of immense boiler shops was begun upon the middle of the property, the residences, lawns and shade trees being undisturbed save for the additions and alterations to the largest residence necessary to convert it into an administration building for the operating staff and drawing rooms for the engineering department.

A map of the property purchased by the company is shown in one of the illustrations. Along the water front a bulkhead for shipment by lighter has been constructed, giving a depth at mean low water of 18 feet. A dock has also been built for vessels of deeper draft. A branch of the Central Railroad of New Jersey enters the north end of the property, and a system of tracks for shipping runs into the various buildings and passes the various places in the yard where the raw material and finished products are stored. These are indicated on the map. Heavy raw materials are unloaded and finished products loaded on cars by two locomotive cranes. Small Baldwin switch engines are provided to move cars about, although the locomotive cranes may also be used for this purpose. The sizes of the buildings are given on the plan. All are of brick and steel construction with curtain walls and steel roof trusses supported by steel columns. Monitors and skylights give ample light and ventilation. Warren-Ehret slag and asphalt roofing is used. The machine and drum shops are divided into three bays by interior rows of columns. The middle bay in the machine shop is fitted with a 50,000-pound electric traveling crane built by the Niles Tool Works Company and a 10,000-pound Shaw crane built by Manning, Maxwell & Moore. There is a 10,000-pound Niles crane in the middle bay of the drum shop and also a Shaw crane of the same capacity. In the side bays the heavy parts are handled by jib cranes attached to the building columns or to the machines they serve. Most of these consist of a horizontal beam on which is a horizontally moving trolley, the vertical leg of the crane being the extension of an hydraulically operated piston for raising and lowering it. These cranes are arranged to swing about the vertical leg as an axis.

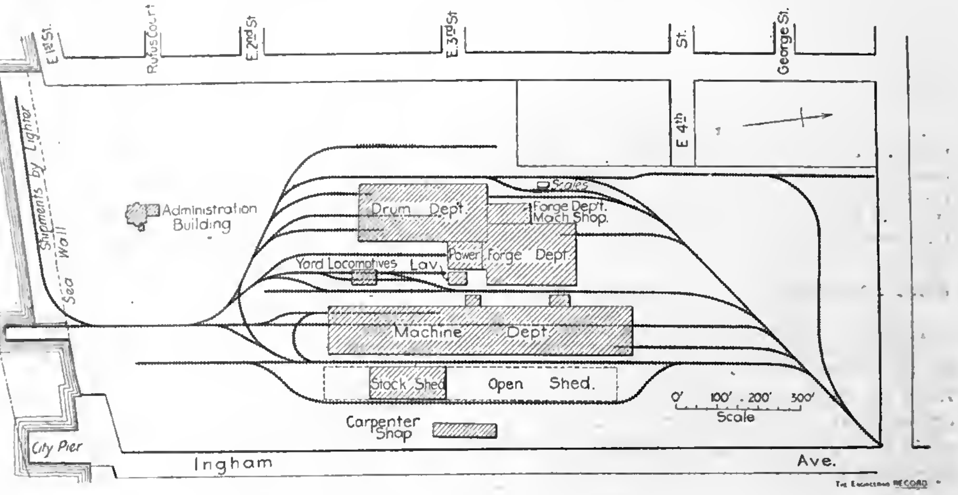
In the construction of the Babcock & Wilcox stationary boilers, which are of the sectional water-tube type, the work, for the purpose of this description, may be divided into three separate operations. One of these is the construction of the drums and cross boxes, the latter being forgings riveted to the drums to which the vertical pipes from the tube sections are connected. The second operation is the construction of the tube sections comprising the forging and machining of the headers, hand hole covers, etc., the assembling and testing of the sections, each of which consists of a pair of headers connected by a number of 4-inch tubes. The third is in the construction of wall fittings, fronts, grates, etc. The stationary boilers are not assembled complete until they arrive at their destination, although the marine boilers are assembled completely and tested before shipment. The headers are of cast iron or of wrought steel; the percentage of boilers with wrought-steel headers is rapidly increasing, and those with cast-iron headers, diminishing. The plan of the buildings shows the location at which the raw materials are stored.

Forge Shop.—The work done in this shop may be divided into three classes: First, the forgings which are required in the construction of the steam drums, such as cross boxes, drum doors, frames, etc., used on marine boilers. The forged-steel buckstave has been developed by this company to overcome the objections which always occur in the casting and transportation of the long cast-iron buckstaves which are ordinarily used. Arrangements are made for utilizing the waste heat of the two furnaces in which the header and cross box plates are heated for heating the small plates required for hand-hole fittings.

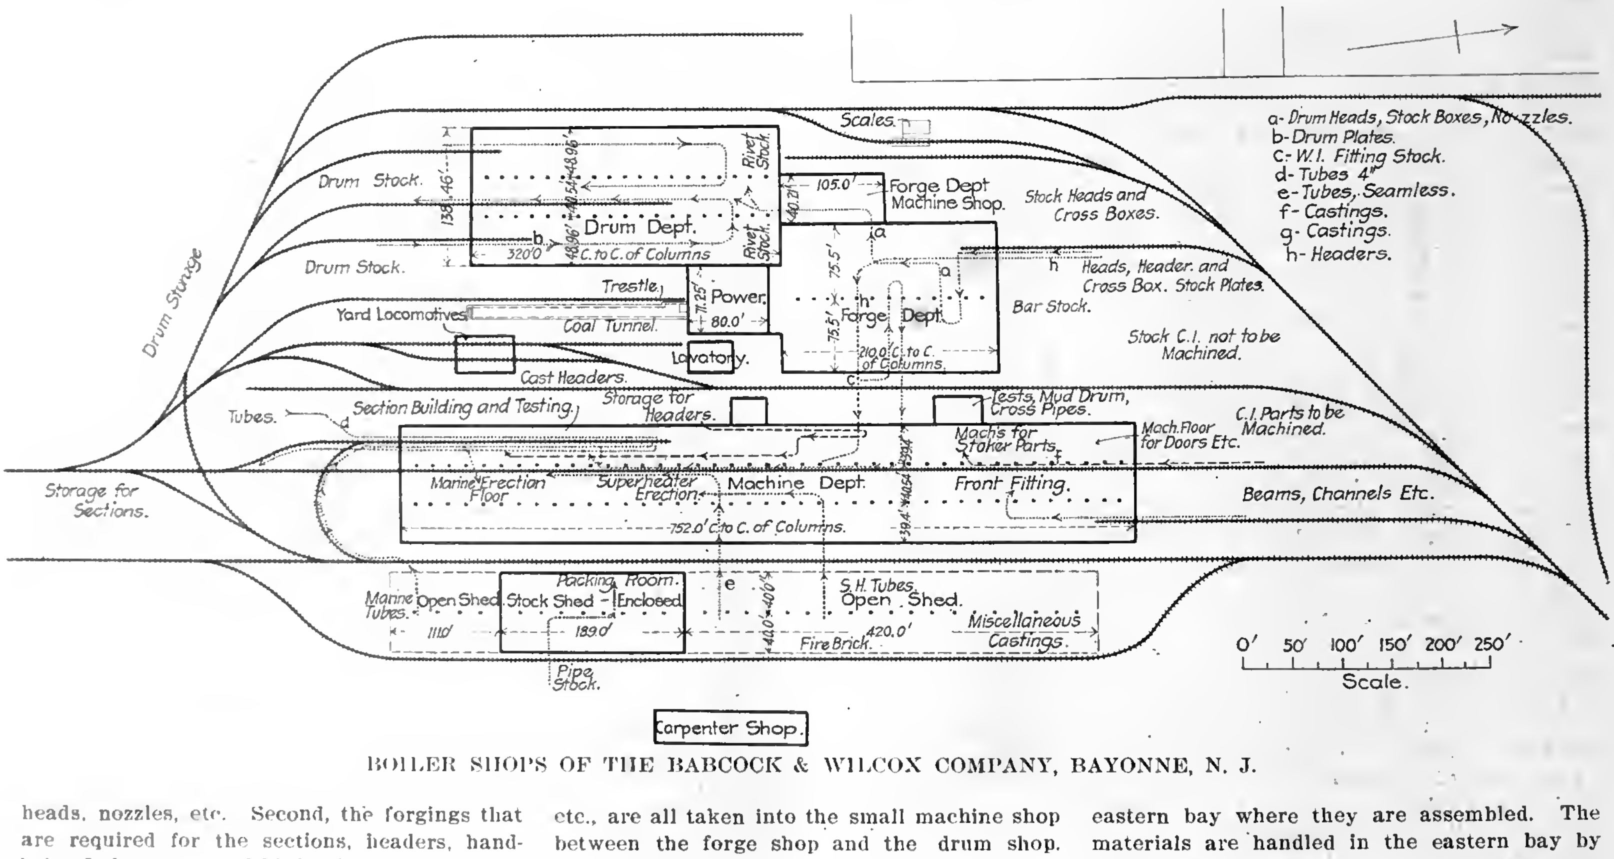
The only tools in this shop are the shears for trimming the rough edges of the cross boxes and the grinding machines for finishing these edges. After these two operations are finished, the cross boxes, drum heads, nozzles, the operations connected with the riveting to them of the parts mentioned.

The operations in connection with the manufacture of the headers consist in scarfing, folding, welding, corrugating, flanging of the hand holes and welding in of the ends. For all of these operations special machinery has been developed. After these operations are completed in the forge shop the headers pass into the machine shop for the finishing, which will be described.

Machine Shop.—The northern end of the machine shop is devoted to the fitting and assembling of the boiler fronts, supports, etc. The beams, channels and plates required enter the



MAP OF BABCOCK & WILCOX PROPERTY.



BOILER SHOPS OF THE BABCOCK & WILCOX COMPANY, BAYONNE, N. J.

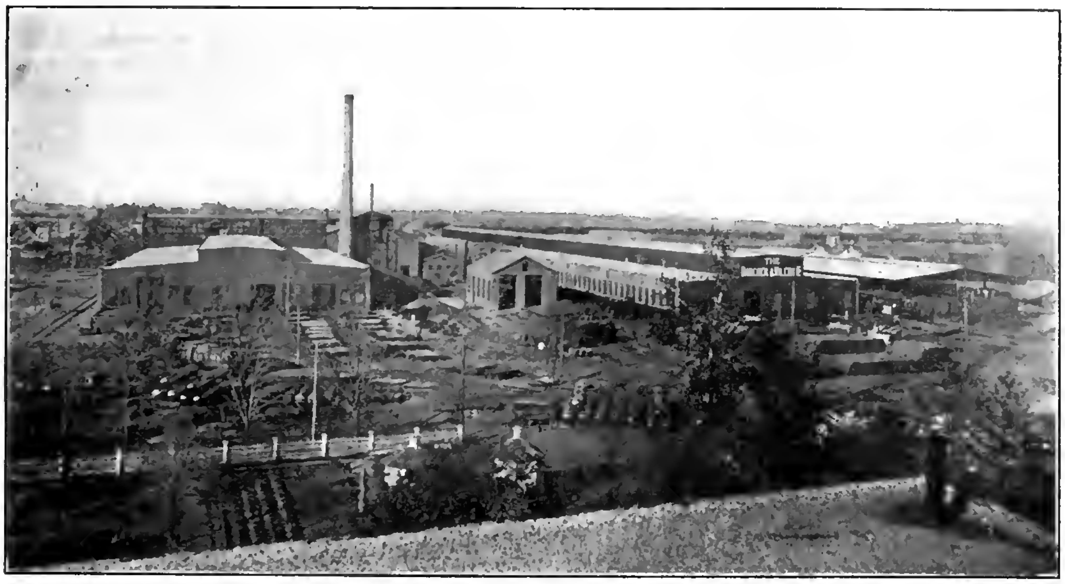
heads, nozzles, etc. Second, the forgings that are required for the sections, headers, hand-hole fittings, etc. Third, the miscellaneous forgings required for non-pressure parts for special work like doors, buckstaves, and work of that character. The extreme north end of this shop is occupied by the blacksmiths' fires, and adjacent to these are the furnace and presses required for making the drum heads, cross boxes and nozzles. The south end of the building is occupied by two welding furnaces with the necessary presses required for shaping and corrugating the headers. In addition to the aforementioned machinery, the forge shop also contains presses for the manufacture of the forged-steel buckstaves and the forged fire-etc., are all taken into the small machine shop between the forge shop and the drum shop. This contains a number of lathes, radial multiple drills, planers, boring mills, etc., for facing and drilling drum heads, nozzles, man-hole plates, etc. The circumferential flange of the drum head and the inwardly projecting man-hole flange are dressed off in a boring mill, both operations being performed at the same time. A multiple machine for boring the several tube holes in the cross box where the tubes enter it is shown in one of the photographs. The completed nozzles, drum heads and cross boxes enter the drum shop at the north end at a point where the drums have been rolled, assembled and riveted ready for eastern bay where they are assembled. The materials are handled in the eastern bay by hydraulically operated jib cranes attached to the columns of the building or to the machines in which the various operations are performed. In the middle bay, the fronts, supports, etc., are handled by the traveling cranes by which they are loaded on cars for shipment when finished. In the north end of the west bay the machine work and the assembling of the mechanical stokers is accomplished, and also the machine work upon furnace doors, etc. About two-thirds of the west bay is devoted to the machine work upon the headers. The cast-iron headers have the tube holes bored out and the hand-hole openings bored and ground.

The wrought-steel headers are of two types, those in which the cap covering the hand-hole is outside and those in which it is placed inside the header. The tube holes and hand-hole openings in both types are made in multiple cutters. On some of the headers, those with the hand-hole plates on the outside, the opening is flanged outward, dressed and then ground so that the metal joint will be tight without a gasket. With vertical headers having inside hand-hole plates, each hand-hole opening has to be elongated in a vertical direction to make an elliptical opening so that the tube may be drawn through it. This is done by drawing through it by means of hydraulic pressure a die of elliptical cross-section. The inner edge of the opening has to be dressed and ground, as does the bearing edge of the plate, which is of wrought steel pressed into shape by an hydraulic press. After the machine work on the headers and hand-holes is completed, the sections are formed by placing the tubes in the headers, then a section is laid upon a slightly inclined table and a workman at each end of a section expands the tubes into the headers by means of an expander driven by a flexible shaft operated from a carriage that moves on a bed lying parallel to the headers. The hand-hole plates are then put in place and hydraulic test pressure is applied to the section. If inspection shows it to be tight, it is lifted by a jib crane to a car, where it is painted and then conveyed to the storage for sections.

In the central part of the main bay of the machine shop, which is served by the traveling cranes, are a number of heavy tools largely used in constructing machinery for the works. South of this is the section devoted to the machine work and the assembling of the superheaters, which consist of U-shaped seamless tubes connected at each end to headers through which the steam enters and leaves. The south end of the east and middle bays is devoted to the machine work upon the marine boilers and to erecting and testing them. The erecting department is in the middle bay, and when they are completed they are lifted by a traveling crane and placed on cars for shipment. The enclosed stock-shed east of the machine shop contains brass tubing, water gauges, gauge cocks, blow-off and feed valves and other details that are supplied with a boiler. They are packed here and shipped on cars from covered loading platforms on each side of the storehouse.

Drum Shop.—Material enters the southeast corner of the drum shop on small flat cars. It is first marked so as to show the rivet spacing and the lines to which it is to be trimmed. It is then lifted by hydraulically operated jib cranes to the punches. These are of Hillis and Jones make, and are provided with a table with rolls on which the plate rests, and a sliding carriage to which the plate is clamped serves to advance the plate in the punch. A rack and pawl device insures the rivet spacing being of the proper pitch. The plate then passes to the shears where the edges of the plate are trimmed. They are then beveled on the edges in a machine where a horizontally moving tool cuts the edges, the plate being held in position by hydraulically operated pistons. The plates are then rolled into cylindrical shape. The frame supporting the bearing for one end of the upper of the three rolls is moved out of its position hydraulically so that the rolled sheet can be drawn out of the rolls endwise.

By this time the plates have reached the north end of the shop and there gap riveters are used to rivet the longitudinal seams in the drum sections and also to punch out the holes in the sections for the cross boxes, steam outlets, nozzles, etc. In some cases the cross box is riveted to an end section of the drum. While the riveting is being done the drum sections are suspended from a trolley moving on a horizontal I-beam that is itself suspended at both ends by wire ropes carried up and over pulleys and attached to the piston of a cylinder in which hydraulic pressure serves to raise or lower the drum section. Horizontal motion of the drum is secured by means of the trolley



VIEW OF BABCOCK & WILCOX SHOPS.

VIEW OF EAST BAY OF DRUM SHOP.

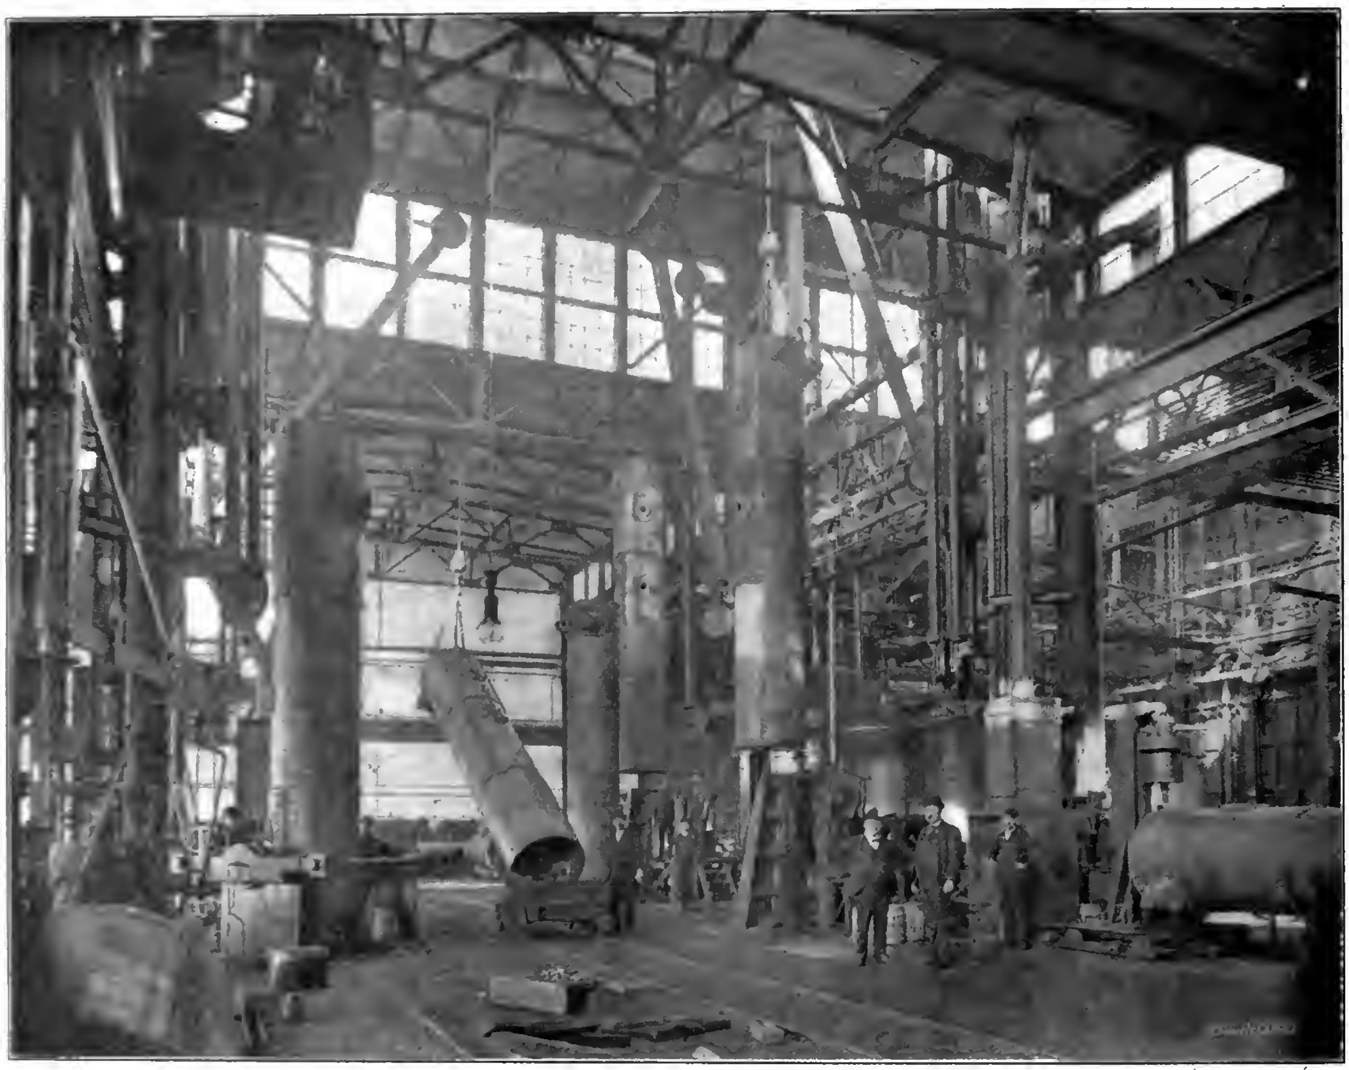
referred to. The riveting of the circumferential seams between the middle and the end sheets is accomplished in the riveting tower which occupies the north end of the drum shop. At the north end of the center aisle, forming part of the riveting tower mentioned, there are four riveters. Two of them are of about 7 feet gap and can be used for the circumferential seams or for riveting on the cross boxes if they are not put on before the sections are assembled. Each of the other riveters is of special design; they have a gap of 24 feet and a stake over which a 36-inch drum can be placed all the way down. The spring which would ordinarily come on this stake is obviated by pitching the rivet holes diametrically opposite and driving the two opposite rivets at the same time. The drum is held in a vertical position, and extending upward on the inside is a mast used to exert pressure against the inner heads of the rivets.

The drums are supported by a boom derrick, so that by raising or lowering the boom, which is done by hydraulic power, the drum is moved away from or toward the mast of the derrick. The mast of the derrick with its attached boom can also be raised or lowered by an hydraulically operated piston so that any desired movement of drum can be accomplished easily and with precision.

The drum heads are dished and as there is a manhole in each head, it is possible to rivet both heads to the shell at once. The shell is laid horizontally on two pairs of rollers so that it may be revolved about its axis. At each end is a riveter resting upon a carriage that can be moved in a longitudinal and also in a transverse direction with respect to the drum. The riveter is mounted upon a vertical support, and it can be moved on this in a vertical direction by means of hydraulic power, so that the lower jaw of the riveter after it is introduced in the man hole opening can be seated on the lower head of the rivet while the upper end is being headed up. As both ends of the drum are riveted at the same time, the work is done quite rapidly.

When the riveting is completed the drums are deposited in the center aisle of the drum shop and are then picked up by traveling cranes and conveyed to the middle of the shop, where they are caulked by pneumatic tools. Before they leave this department, they are tested at 50 per cent. above the working pressure and leaks stopped. They are then painted and lifted on cars and taken to the drum storage in the yard or shipped immediately if necessary. The west aisle of the drum shop is of comparatively recent construction made necessary by the demands of the business. Generally speaking, it will be similar to the east side and the raw materials will enter at the south end and pass northward toward the riveting tower. This part also contains a number of multiple drills used to drill rivet holes out of the solid plate without punching.

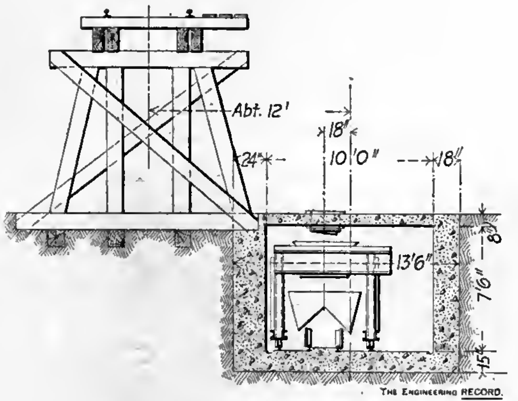
Power Plant.—Power for the shops is generated in a central power station located as shown on the plan. It contains the main engine, which transmits power to the drum shop, to the machine shop in the forge department, and to the forge shop, by means of a system of belts connected to a jack shaft belted from the engine. Belts from this same shaft lead to electric generators that supply current to motors driving the machine shop, carpenter shop, electric traveling cranes and other small machines about the plant that could not be conveniently driven from the belting and shafting system. The power house is divided into an engine and boiler room and the plan and sections of each are illustrated. The boiler room contains two 300-horse-power Babcock & Wilcox wrought-steel boilers suitable for 200 pounds steam pressure. Each is equipped with a Babcock & Wilcox superheater, and a Green economizer is placed in the smoke flue, which discharges the gases into a chimney 6 feet in diameter and 153 feet high. The latter is of the radial brick type, and was constructed by the Alphons Custodis Chimney Construction Company. The boilers are also equipped with two Sturtevant fans driven by a steam engine and discharging air in the ash pits of the furnaces. The fans can be used to augment the draft of the chimney should it become necessary, and they also enable boiler tests to be made at extraordinarily high rates of combustion. There is an additional Babcock & Wilcox boiler and superheater over the plate heating furnaces in the forge shop, and also one over the welding furnaces. The four boilers are connected to a system of steam pipes supplying the engines, pumps, etc., in the engine room.



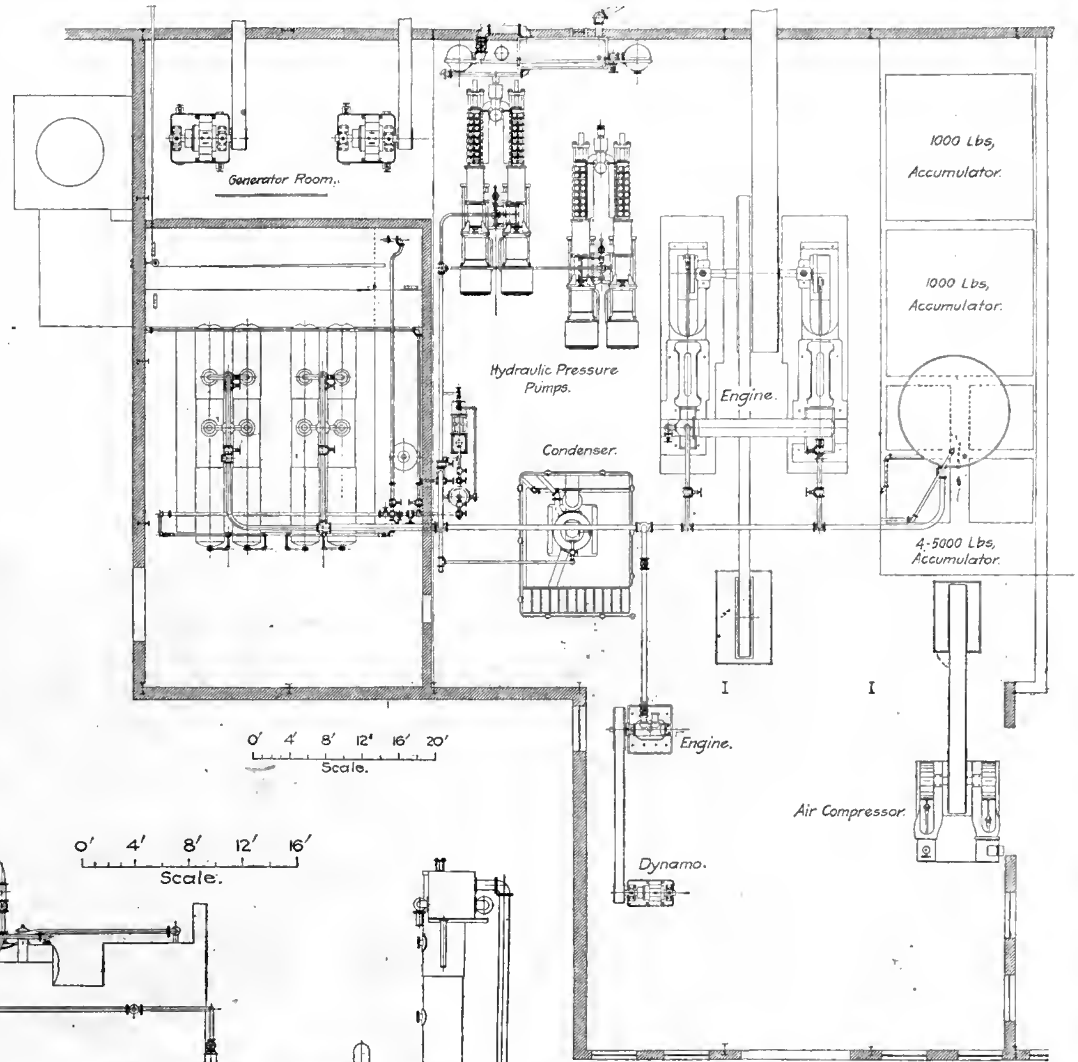
VIEW OF RIVETING TOWER.

Coal enters the plant on cars and is run upon a trestle from which it is dumped in a pile in the yard. Beneath this coal pile a concrete tunnel has been constructed. Openings are provided in the roof of the tunnel at frequent intervals so that the coal may be chuted into a breaker that is driven by a small electric motor and mounted upon a car that can be moved along the tunnel upon tracks provided for the purpose. The bottom of the car is elevated and is arranged to straddle a smaller track; upon this is run a small dumping car, which is filled by the coal that passes through the crusher. The car is then pushed to the power house end of the tunnel upon a platform of a Morse-Williams elevator operated by belt from the main system of shafting. The elevator raises the car outside of the building opposite an opening in the wall of the boiler house, and from that point the car is pushed upon an elevated track to hoppers over the boilers in the boiler room and also to hoppers over the furnaces in the forge shop.

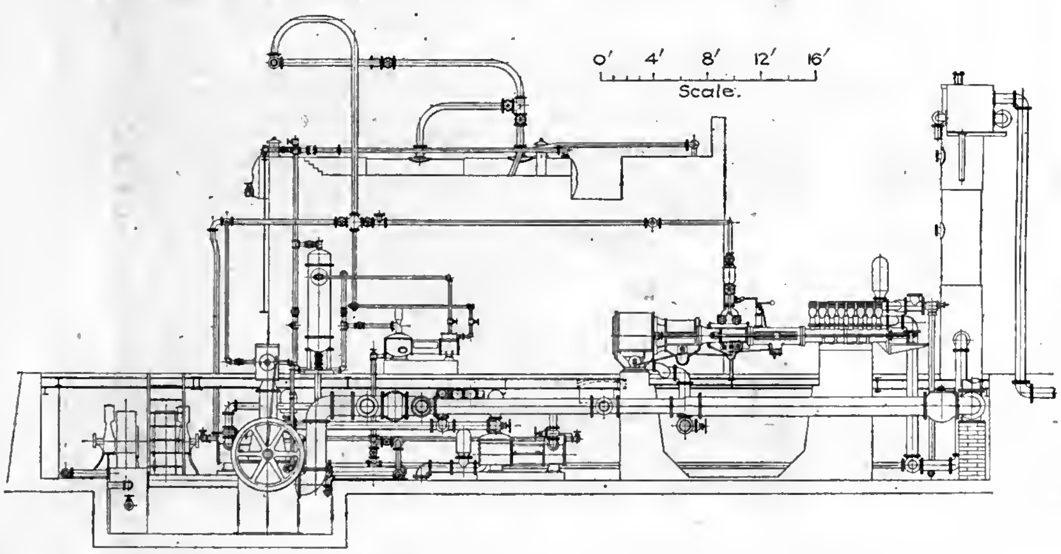
The engine room contains the main engine, the auxiliaries, two high-pressure pumps connected with an hydraulic system and also an electric generating plant. The engine is of the Reynolds-Corliss cross-compound type built by the Allis-Chalmers Company. The cylinders are 16 and 32 inches in diameter with a 42-inch stroke. The rotative speed is 75 revolutions per minute and the steam pressure 140 pounds. The engine is provided with a reheating receiver, and both the high and low-pressure cylinders may be by-passed if desired. The engine may be operated condensing or non-condensing as desired, a 28x16-inch air pump and condenser of the crank and fly-wheel type, provided with Corliss valves, having been furnished by the Allis-Chalmers Company. The pumps, two in number, are of the Worthington triple-expansion type with steam cylinders 13, 21 and 41 inches in diameter with a water cylinder 6½ inches in diameter, all with a stroke of 24 inches. The pumps work against a pressure of 1,000 pounds per square inch. There are also



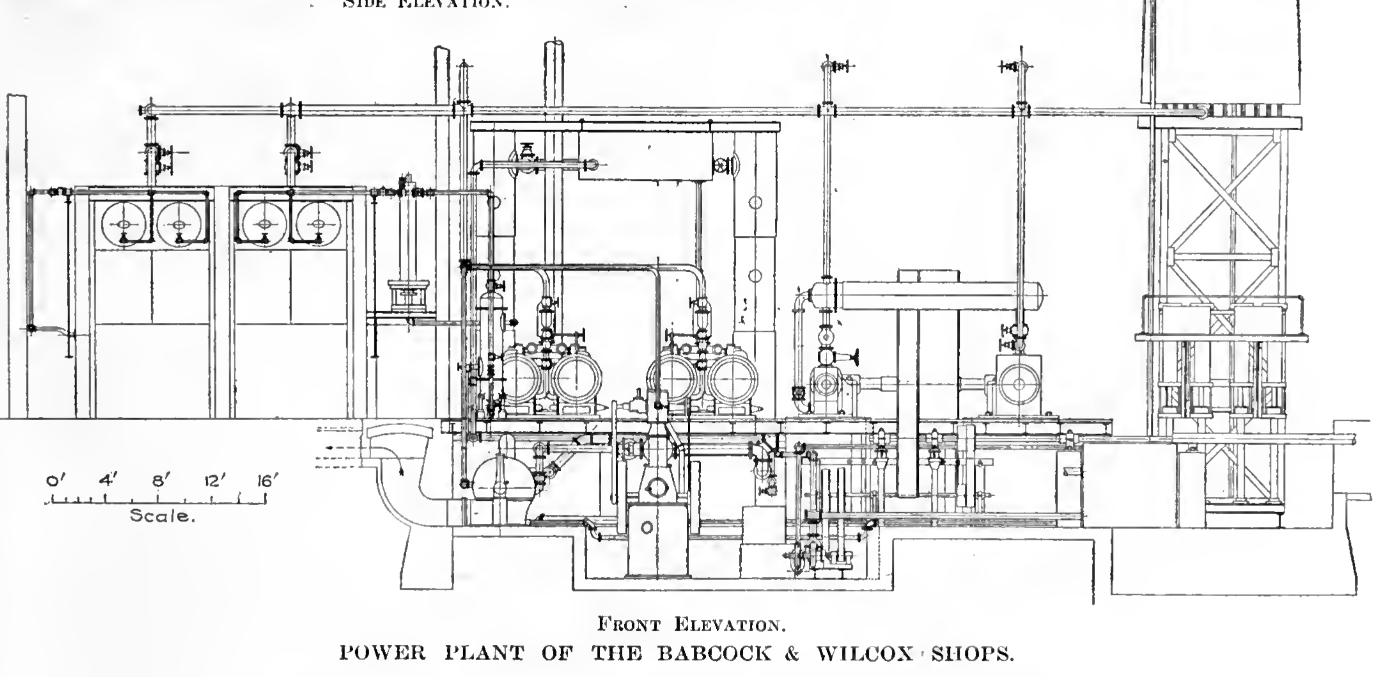
COAL TRESTLE AND TUNNEL.



PLAN.



SIDE ELEVATION.



FRONT ELEVATION.

POWER PLANT OF THE BABCOCK & WILCOX SHOPS.

two Worthington Underwriter fire pumps with 14 and 7¼x12-inch cylinders. These are placed in the basement of the engine room. Ordinarily the main engine and the Worthington high-pressure pumps are operated condensing. The pipe leading to the condensers is provided with an atmospheric exhaust containing a relief valve, as is the usual custom. The exhaust steam from the air pump is also turned into the condenser, while the exhaust steam from the boiler-feed pump is utilized in a feed-water heater made by the Goubert Manufacturing Company.

The fly-wheel of the main engine is 17 feet in diameter and 4 feet 8 inches in width of face. It is turned for a 34-inch belt leading to the main shaft in the drum shop and for a 16-inch belt leading backward to a shaft in the engine room basement. The latter serves to drive two Ingersoll-Sergeant two-stage, Class J, air compressors used to supply pneumatic tools throughout the shop. One of these has cylinders 14 and 7¼x12 inches and one, 24¼x 16¼x16 inches. The electrical equipment was supplied by the Diehl Manufacturing Company and consists of two 125-kilowatt belt-driven generators running 125 revolutions per minute

Each line is belted to a 100-horse-power motor located on the floor at the middle of the bay. There is also a 30-horse-power motor to drive machinery in the carpenter shop, a 10-horse-power motor for job work in the pipe department, and various motors connected to the traveling cranes and to several blowers for the supply of air to the heating furnaces. Means are provided for driving the small blowers for the heating furnaces as fires in them have to be started early in the morning before the main plant is in operation.

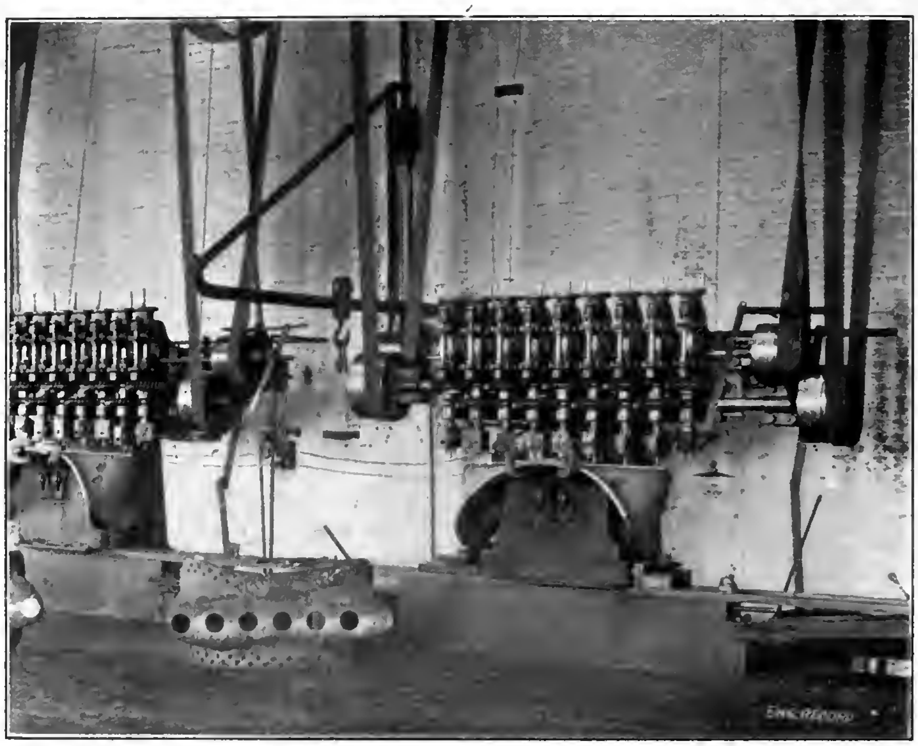
There are five systems of pipes distributed through the shops: four of them hydraulic under 80 pounds, 600 pounds, 1,000 pounds and 5,000 pounds pressure, and an air line of 100 pounds per square inch. Power lines are run to each interior column in the machine, forge and drum shops, so that electric, hydraulic or pneumatic tools may be supplied.

The 80-pound line is salt water obtained from the condenser discharge, and it is connected to an elevated tank supplying the fire protection system, the water closets in the toilet rooms and the testing departments, the drums and sections being filled with this water before the water under higher pressure is turned on.

elevated somewhat to give a pressure on the pump suction and insure smooth operation. The tank is connected to two vertical drums or stand pipes and the pump suctions connect with these at a point about three feet from the bottom, so that mud can settle there, whence it is blown off. The drums are cross-connected at the bottom. The water used for the hydraulic presses is returned to a tank in the engine-room basement and a centrifugal pump elevates it to the suction tank mentioned. This system is connected to an accumulator, which, as it rises or falls, governs the speed of the pumps by means of a cord connected to a pump governor.

The 5,000-pound line receives water from the 1,000-pound system, the pressure being increased by an intensifier which is an hydraulically operated pump receiving water at both ends from the 1,000-pound line, the difference in areas of the two cylinders enabling the intensifier to increase the pressure on the discharge by the amount stated. The discharge from the motor end of the pump returns to the lower tank. The system is also provided with an accumulator governing the action of the intensifier.

Multiple Tool for Boring Headers.



Multiple Tool for Drilling Cross Boxes.

and one 75-kilowatt belt-driven machine running at 550 revolutions per minute. The latter is driven by a Westinghouse compound engine, and is used for lighting when the main engine is not running. The voltage used throughout is 220 volts, and all machines connect with both the light and power service. The lights are controlled by nine circuits connected with the switchboard, one each to the drum shop, forge shop, machine shop, office building, shed, power house and toilet room and two circuits controlling the yard lights. There are five power circuits, two to the machine shop, one to the traveling cranes and drum shop and two to the machine shop in the forge department. There are three lines of shafting in the machine shop. One is in the eastern bay, supported over the interior columns and divided into three sections, each driven by a 30-horse-power motor mounted upon an elevated platform against the east wall. The remaining lines of shafting, two in number, are located in the western bay, one supported over the interior row of columns and the other from the lower chord of the roof trusses close to the west wall.

Salt water runs from the river to a well outside of the power house through an 18-inch brick conduit. The discharge from the air pumps empties into a hot well from which a centrifugal pump elevates water to the elevated tank for the 80-pound system. The remainder of the condenser discharge goes to waste in the sewer. While the fire protection lines are connected to this system, they are also connected to the fire pumps which can draw water from the city mains, and by means of the closure of a check valve in the connection to the tanks the pumps can increase the pressure on the fire-protection system.

The 600-pound line is supplied by a double-plunger pump located in the forge shop and belted to the shafting. This pump draws salt water from the elevated tank and the system is used to test headers, drums and boilers. An accumulator is connected to this system, and as the pump is belt-driven, the pump is arranged to by-pass when the accumulator is filled.

The 1,000-pound line contains fresh water that is drawn from a tank in the engine room,

The 80-pound line is composed of standard wrought-iron pipe and screwed fittings; the 600-pound line of extra heavy pipe and extra heavy screwed fittings; the 1,000-pound line of extra heavy pipe and extra heavy screwed fittings; and the 5,000-pound line with double extra heavy pipe and double extra heavy malleable fittings. The 1,000-pound line is used for hydraulic riveting and operating hoists, etc., and the 5,000-pound line for the heavy bending, flanging and forming processes in the forge and drum shops.

The boiler feed-water can be drawn from the city mains, from the fresh water tank for the 1,000-pound hydraulic system, from the heating system, and, in cases of emergency, from the salt-water supply. The boilers are operated under a pressure of 200 pounds per square inch, but the elevated position of the boilers over the heating furnaces in the forge shops requires that a slightly greater pressure be exerted or about 210 pounds over the feed pump discharge. To control the speed of the pumps and insure quiet running to meet this unusual condition an accumulator is placed in the boiler feed line and the position of the accumulator is utilized to control the speed of the pump which works against a constant head of about 210 pounds. The boiler-feed pump forces water through the Goubert heater, the Green economizer and thence to the boilers. The heater and economizer may be by-passed if desired. The returns from the heating system are carried back to an automatic pump and receiver and are delivered to the feed line inside of the feed pump.

The heating system of the buildings comprises direct radiation. It was designed by the Paul System Company and installed by Baker, Smith & Co., of New York. Wall coils are used to counteract the cooling effect of the windows and ceiling coils are run along the interior row of columns in the machine and drum shops to offset the heat loss from the windows in the sides of the monitors. Exhaust steam from the main engines, pumps and auxiliaries is used for heating, although live steam at reduced pressure may be used if desired. The Paul system of relieving the heating apparatus of air is employed.

Excellent sanitary arrangements are provided for the workmen; a special building containing lavatories, closets and shower baths. A Merritt expanded metal locker is provided for each employe, and these are placed around the buildings convenient to where the men are working. A separate locker room is provided for the employes of the forge shop.

The contractor for the steel work of the buildings was the Riter-Conley Manufacturing Company, of Pittsburg, Pa. Mr. John W. Ferguson, of Paterson, N. J., was the contractor for the masonry and carpenter work. The shops were designed by the engineers of the Babcock & Wilcox Company, and the supervision of the contract work was in charge of Mr. S. J. Harwi assisted by Mr. M. M. Price, both of that company.

The Public Bath at the Fourteenth Street pumping station, Chicago, gave 58,603 baths during 1901.

Transit Dues on the Suez Canal are to be reduced 50 centimes (9.6 cents) a ton on and after January 15, 1903.

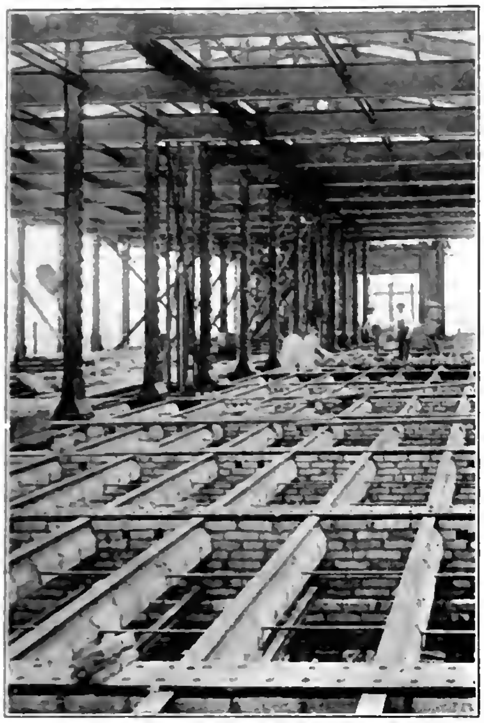
DETAILS OF FLOORS, ROOF AND FIREPROOFING.

Floor Construction and Fireproofing in the Government Printing Office, Washington, D. C.

The new building for the Government Printing Office is U-shaped in plan and has fronts of 408 feet on G Street and 175 feet on North Capitol Street, with a 30x165-foot light court between the two main wings. It has a basement, seven stories and a loft, rising to a height of about 132 feet above the sidewalk. It has steel columns and girders and principally brick masonry and is being built under an appropriation of $2,429,000.00 for its construction and equipment. Captain John Stephen Sewell, engineer corps, U. S. A., is in charge of construction, and under his direction the structural work has been completed.

Every floor is proportioned for a maximum dead load of 125 pounds per square foot and a quiescent live load of 300 pounds per square foot. Where the live load is a vibrating one it will not exceed 125 pounds per square foot. It was thought justifiable to use an unusually high unit stress in the steel work and to require a high quality of materials and workmanship. A unit stress of 18,000 pounds per square inch was therefore adopted for I-beams and girders, and it was required that all rivet holes should be punched small and reamed after the pieces were assembled. Open hearth steel with an ultimate strength of 63,000 to 70,000 pounds and an elastic limit of at least 55 per cent. of the ultimate was specified and the amount of steel required was thus reduced 800 tons below what would have been required if the work had been proportioned for ordinary unit stresses.

The main columns are about 12 feet apart in six longitudinal rows with one center space of about 31½ feet and four side spaces of about 35 feet between the rows. All the floors above the first have 30-inch transverse plate girders about 12 feet apart, which support longitudinal



Fireproofing for Floor.

floorbeams about 3 feet apart, but do not carry the wall masonry. The girders are made without web stiffeners except over the end bearings, where they rest on shelf connections riveted centrally to the column webs, and are not web riveted to the columns. The ends of the girders project between the webs of the wall columns, and are seated on horizontal angles riveted to vertical diaphragms which connect both column webs as shown in the elevation of one end of the girder. The opposite end is supported in the usual manner by a shelf angle having its flange reinforced by vertical angles riveted to the face of the interior column. At both ends of the girder horizontal angles are riveted across the top flange and to the face of the column. In some cases 20-inch 70-pound I-beams are used instead of the girders, and are supported by substantially the same column connections.

On account of their long spans the floor girders are so deep that there is a considerable distance between the floor and ceiling which together enclose all the steel construction, and the ceiling is supported on separate longitudinal I-beams, independently of the floor. The floorbeams have their top flanges flush with those of the girders and are beveled to clear the latter. In order to carry the tension stresses of horizontal forces in the planes of the floors those beams near the walls have their top flanges spliced together by horizontal plates field-riveted across the girder flanges. The regular connections of the beams to the girder webs were considered almost strong enough to transmit the maximum tension from wind stresses, but the tie plates were added as a precaution and to make the building much stronger horizontally.

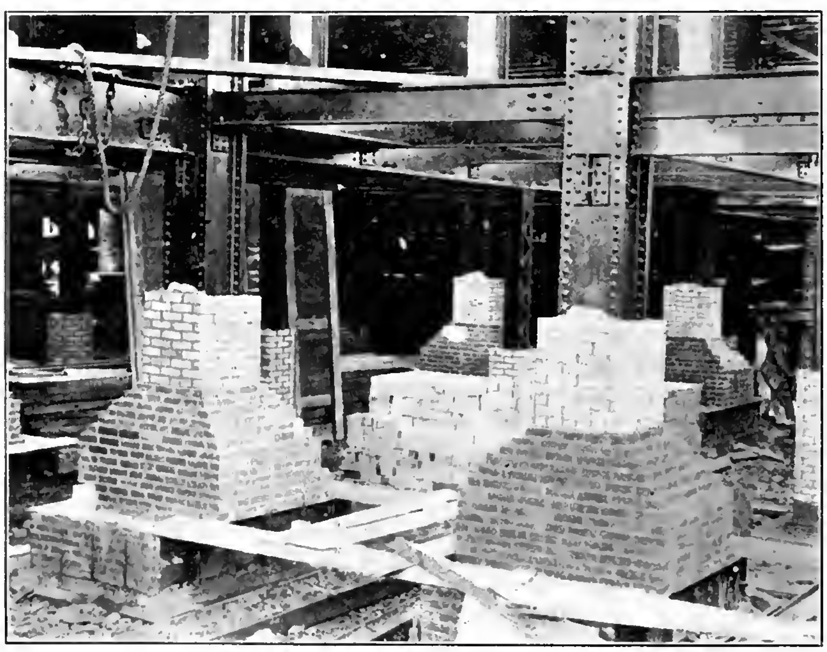
In the regular panels the ceiling beams are web connected to the girders, but in some special panels the floorbeams are transverse and are connected to 20-inch longitudinal I-beams about 2½ feet long and 7 feet apart which are web connected to the main girders. Here the ceiling beams clear the bottom flanges of the longitudinal beams, and are suspended from them with U-bolts as shown in the detail. In the first floor the main transverse girders are 20-inch I-beams, spaced like the plate girders in the upper stories and supporting 10-inch longitudinal beams about 5 feet apart. Each

Fireproofing for Ceiling.

of them is supported in the center by a single story basement column over the top of which the beam is continuous. At one side of the building there is under the sidewalk a storage vault about 20 feet wide and 230 feet long, which is covered with a solid floor having 10-inch transverse beams, 6 feet apart. These are supported at both ends on the vault walls and in the middle by a line of 15-inch longitudinal beams carried on cast iron columns about 12 feet apart. The double pitched roof has, in the planes of the floor girders, 20-inch I-beam rafters, supported on the center and wall columns, and carrying 7 longitudinal lines of 7-inch I-beams about 7 feet apart.

The machines in the building are driven by a large number of individual electric motors, and as it is necessary from time to time to change the arrangement of the machines and the electric lights the floor system was designed with especial reference to the convenience of relocating the motors and wiring system and so that holes could be easily cut through or be filled up in any place without injury to the strength of the construction. Lights suspended from the handsomely finished ceilings must also be moved without disfiguring the ceiling, and it was decided to take advantage of the space afforded by the depth of the long span girders to make the floors and ceilings separate with sufficient space between them for a man to pass through all places between girders, and to run all wires and cables in this space where they are protected from fire and are always accessible through manholes. To this end the floors have been built and the girders fireproofed, as shown in the view of the underside, and then the wiring has been done before the ceilings were built. Subsequent changes will be made by men crawling between the floor and ceiling.

In bidding for the fireproof floor construction contractors were requested to submit plans of special construction to conform to the conditions and requirements, but most of them failed to modify their usual types, and all bids were rejected. Specifications were then prepared and contracts awarded on them for segmental brick arches for all the main floors and for reinforced concrete flat slabs for roof, ceilings and stairways. The segmental floor arches 4 inches thick are made as shown in the detail sections, with solid porous terra cotta bricks set on very heavy skewbacks of the same material which have projecting lips 1½ inches thick to protect the lower flanges of the floorbeams. These lips, which are usually the weakest point of a beam protection, meet with a very thin mortar joint and are believed to be strong enough to resist any ordinary fire stream unless accompanied by prolonged and very intense heat. Where it would have been difficult to build the brick arches on account of irregular beam framing or where it was desired to have a sloping floor on level beams, the arches were replaced by steel-concrete slabs with the beams entirely enclosed in the concrete, as shown in the sections of the roof. The arches are leveled up with concrete above the tops of the steel beams, and in the working rooms the floors are finished with hard maple blocks, laid herring bone pattern in Neuchatel asphalt.



Fireproofing for Columns.

Originally the floorbeams were designed to be 12-inch I-beams 6 feet apart, thus affording space for a man to crawl only in the middle between each pair of beams under the crown of the 4-inch floor arch, but not allowing him to cross over the ceiling beams from one panel to another of the floorbeams. It was afterwards thought better to make the floorbeams only 8 inches deep and 3 feet apart, thus enabling a man to crawl under them on the ceiling and saving about 60 per cent. of the manholes and their expensive framing, an economy that offset to a considerable extent the extra cost of the several hundred tons of additional steel in the floorbeams.

The ceiling beams are 3 inches deep, about 3 feet apart, and support on their lower flanges transverse T-bars 2 feet apart. The T-bars carry 2-inch slabs of cement and sand reinforced with steel roofs. These slabs have drop ends which bring the lower sides below the I-beams and T's and leave the top flanges of the I-beams exposed, ready to carry insulators. The wires can be strung from the tie rods between the webs of the main floorbeams which were not considered necessary as tension members. Holes were punched through the girder webs and enameled iron pipe conduits are put through them to carry the main electric cables and protect them, while leaving them accessible.

The lower flanges of the main girders are protected by shoes of solid porous terra cotta, 2½ inches thick, filled with mortar and squeezed on. They are then wrapped with wire lath, plastered with cement mortar, and the 4-inch walls of solid porous terra cotta are built up each side of the girder web, and the spaces between the terra cotta and the girder are filled solid with cement mortar. Where the columns are not enclosed in the walls of red bricks made of unusually refractory clay, they are fireproofed by a 4-inch thickness of porous terra cotta enclosing them, and the spaces inside the columns and between them and the terra cotta are filled solid with Portland cement concrete.

The roof is made, as shown in the detail, with flat slabs of concrete about 5 inches thick reinforced with steel bars and extended to enclose and protect the purlin beams. It is divided into panels about 12 feet wide which reach from the eaves to the ridge, and are bounded on all sides by expansion joints. The longitudinal joints at the ridge and at the eaves are filled with asphalt, 1 inch wide and 3 inches deep. The transverse joints ⅜ inch wide are filled with thin pine strips bedded edgewise in the concrete. The stairs have steel girders and strings which are enclosed in the solid concrete moulding for the steps, as shown in the detail.

The brick walls terminate at the loft floor, where the lower courses of the terra cotta cornice are bonded into them. The cornice blocks are supported partly from a pair of 6-inch channels and a single line of 6-inch channels carried on horizontal brackets riveted to the columns. They are also anchored into the solid concrete backing which fills their concavities and locks them together while forming a massive gutter, on the inner edge of which there is a thin brick face wall built up to the eaves and backed with concrete, to which the brickwork and cresting is anchored. All terra cotta is made of very refractory, tough clay and is set, without grouting, in 1:3 American Portland cement mortar. The terra cotta and concrete used were, 4-inch brick arches, 311,000 square feet; ceilings, 227,900 square feet; roof, sidewalks and stairways, 101,100 square feet; rolled and riveted girders, 35,100 linear feet; columns, 4,438 linear feet. The terra cotta was furnished by the Fawcett Ventilated Fireproof Building Company, Limited. The concrete floors and roof were built by the Brennan Construction Company. The common bricks and red face bricks were furnished by the Frederick Brick Works, the enameled brick by Andrew Ramsay, and the white face bricks by E. R. Diggs & Co. The Phoenix Iron Company is the contractor for the structural steel work.

The Practical Operation of Sewage Purification Plants.

Paper prepared for the Annual Convention of the American Society of Municipal Improvements, at Rochester, Oct. 10, 1902, by John W. Alvord. Slightly condensed.

The revolution in sewage purification processes which has taken place in the last six or eight years has brought to the front a good deal of intelligent discussion on the proper design of sewage purification plants based on the new biolytic methods, and there has been a large amount of investigation into the chemical and biological processes involved, both by experiments in the laboratory and by means of miniature installations. All of this has been extremely necessary, interesting and valuable, but it must always be realized that much more valuable information as to the real nature of the problem has been already secured and will be secured from the study of the actual operation of full-sized working plants than will be obtained from any other source of information.

Financial Disadvantages.—The purification of sewage is not generally a popular municipal project. It is often undertaken as the result of long litigation, and by reason of some adverse court decision compelling action. A sewage purification plant produces no revenue, and it cannot be said to be a paying investment financially, except when viewed in the most indirect manner. Unlike water works, sewage plants cannot grow in value with added years, through the increase of municipal business, but must rather become year after year an added burden to the city officials, not only for proper maintenance but for important and necessary extensions as well. It therefore generally happens that officers charged with the care of such plants are desirous of economizing in various ways, in the endeavor to show that they may save their city useless expenditures, which predecessors in office had not found possible. Often the curtailment of necessary appropriations results in practical abandonment. Certain plants may be pointed out to-day in which official mismanagement, and not poor design, is responsible for apparent failure. Scarcely ever may the plant be found which is properly financed after the first year or two.

Physical Unattractiveness.—The subject of sewage purification is not an attractive one to the average citizen. A plant has usually to be located out of sight so that it may be out of mind. The idea is prevalent that it is a municipal eyesore, to be hidden if possible, which may be a necessary evil, but never a source of interest. Common imagination credits it as being a place of bad odor and revolting conditions, which must be avoided when one walks or drives. The idea that it can be a place of interest and source of information is only acquired after it has proved its inoffensiveness, and the slightest relaxation from a good record creates a prejudice which weeks of good conduct cannot overcome.

Termination of Expert Supervision.—The termination of the expert supervision of a sewage purification plant usually takes place a few weeks after its completion. The engineer who had charge of its design and construction, studied every phase of its environment, knows the kind, quantity and variations of the sewage to be dealt with, understands how such variations are to be met, and who will be equal to any emergencies, is dismissed and the plant is turned over to a place hunter, perhaps, or is forced on some unwilling city officer with other duties which already fill his time. This is wrong, and to this condition can be traced many cases of dissatisfaction on all sides. The engineer who has carefully designed and constructed a sewage disposal plant should be retained to supervise its operation for at least a year after it is started.

Tendency to Over-confidence.—One does not have to be long interested in sewage purification to observe the tendency to undue optimism among those engaged in planning or promoting sewage works. Not only is this the case with those connected with patented or proprietary processes, but even engineers designing or constructing plants are rather prone to enthusiasm over prospective performances. This is noticeable particularly in the many descriptions of new plants which are published. It is of course interesting and valuable to have these published accounts and know how each designer proposes to meet the problem he has to face, but new plants do not add to our information as to how sewage purification should be operated. A plant should be six months old before it is interesting and a year old before it is valuable from the standpoint of operation. Two years' operation ought to enable one to form an opinion of it, and three years ought to decide its merits if carefully worked all of that time. Too often the plant is pronounced a success by its originator in the first few weeks, and if a few good analyses, not difficult to obtain in new plant, can be added to the statement, so much the better.

Proprietary Claims.—The endeavor to obtain a monopoly of the field of sewage purification by the owners of proprietary processes and patented claims has for some time past made it difficult for the sanitary engineer to hold his field of activity in this line of work without some embarrassments. It is not easy to convince city officials that sewage purification is a matter in which study and constant care in operation will tell, in the long run, better than the guarantee of a strongly financed company. There is no patent now in the field that is particularly useful or valuable, as has been well shown by Mr. Leonard Metcalf, in his paper before the American Society of Civil Engineers. It is coming to be seen that in large plants skilled operation is as necessary as intelligent design and construction.

The Septic Tank.—It is frequently assumed that the septic tank once installed needs no particular supervision, that it operates wholly without attention, save, perhaps, a yearly cleaning. Now it has been well demonstrated that this is not true; that the septic process is, like all sewage processes, subject to natural variations which must be watched and governed if the best results are to be expected. The particular function of the septic tank is to break down the suspended matter into a manageable state. That this result can be attained by properly designed tanks, carefully operated, has already been fully demonstrated. The compartment system of control, original with the writer, allows the operator of a plant to adjust the fermentation period of the sewage to its quality, the temperature of the weather, and the volume of flow, regardless of the total capacity of the tank. This is accomplished by dividing the tank into a number of compartments of unequal size, opening into each other by troughs and gates, so that one, two, three or more may be combined as may be desired. Thus, if a tank has been constructed for large future requirements, and the early sewage reaching the plant is small in quantity and weak in quality, indicating the desirability of a brief rest period in the tank, enough compartments may be cut out to produce the desired result. The colder temperature of winter invariably lengthens the fermentation period, and in such cases an added compartment may be thrown into use. A thick and concentrated sewage requires a longer fermentation period than a thin and dilute one. An increasing flow of sewage, due to growth of the city or increased number of connections, may be provided for by the use of an increased number of compartments.

Evidence of Proper Regulation.—To one who has watched the effect of this method of regulation on the character of the effluent of the septic tank, no question could arise as to its importance and necessity. The addition or deduction of one compartment in a five-compartment tank will ordinarily produce an effect on the effluent easily determined by the unaided eye of anyone who has had experience in judging sewage effluents. An effluent producing a marked odor of sulphuretted hydrogen has usually been too long within the septic tank and is difficult to treat in the second, or anaerobic stages. It has been clearly shown that the nitrification of such effluents is exceedingly difficult or impossible, and the theory is advanced that the anaerobic bacteria have created toxins inimical to their own life and activity. A septic tank whose effluent shows advanced decomposition is plainly too large for the quantity then flowing, and the best results cannot be expected nor obtained in the secondary treatment of the impurities. On the other hand, an effluent containing large quantities of suspended matter suggests that there is not a proper length of fermentation period to break down the suspended particles. The writer has frequently observed the addition or deduction of a compartment to show a distinct and marked influence on the suspended matter coming over from the septic tank. The sewage enters some septic tanks in such a way that it evidently traces a path through the center, and its stay is not well averaged. This difficulty can only be obviated by modifications in design which will more evenly distribute the incoming sewage. By the experimental use of coloring matter it has been observed that great improvements may be made in evening the flow by multiplying the number of inlets and carefully arranging them so that the liquid shall be as evenly divided between them as possible.

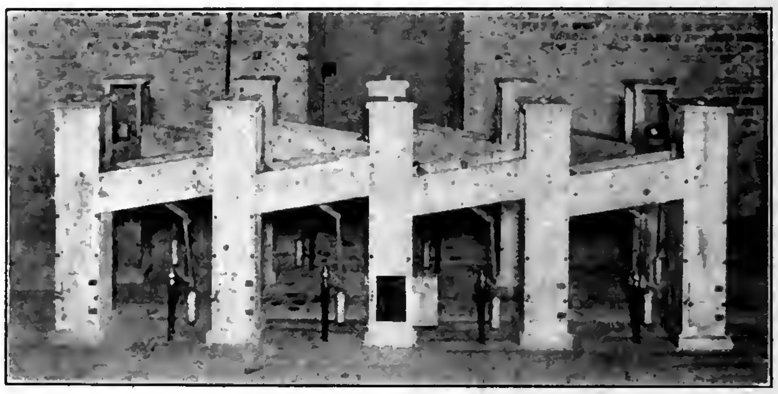
Effects of Proper Regulation.—The proper regulation of the septic tank is of great importance not only because it produces high efficiency for the tank itself, but because it also enables the secondary stages to be operated with equally high efficiency. A septic tank effluent which is in advanced stages of decomposition is not easily reducible in the secondary application, and an effluent containing much suspended matter will check and clog the secondary filters in a short time. The ideal septic tank effluent is one in which the organic matters in suspension have been resolved into the constituent gases or dissolved in solution, and in which no suspended matter is present or no serious decomposition observable. This result is usually obtained with average domestic sewage in this country with from four to eight hours' fermentation. Some particles of suspended matter may from various causes be detained in the tank many days while others are hurried on to the outlet.

Where septic tanks are followed by intermittent filtration, proper regulation insures a minimum of labor in caring for the beds; and it is also observable from actual experience that tanks properly run do not accumulate sludge to any considerable extent on their bottom or an undue thickness of scum at the top. Of the 17 tanks which the writer has so far installed and watched, in some cases over four years, only one has had to be cleaned so far, and in this case the occurrence was due to an only partial familiarity with this principle since satisfactorily demonstrated.

Fallacies of Analysis.—Contrary to the usually accepted opinion, the proper operation of sewage purification plants does not at all require that analyses be taken in order to understand and govern operation. There are many signs by which one may judge of the efficiency of a plant without resorting to the tedious and delicate work of the chemist or bacteriologist. For instance, flaky black matter in the effluent is evidence of more or less completed decomposition, and quantities of white humus are likewise indications of insufficient anaerobic action. Ordinarily in plants which are not imperiling a neighboring water supply it is thought sufficient if secondary decomposition be prevented. This is easily determined by sealing a small quantity of effluent in a bottle and letting it stand for two or three days. The appearance of black flakes by this time denotes that the impurities were not wholly removed, while the non-appearance of such black ash, and the absence of any odor of ammonia when the bottle is uncorked would ordinarily denote results entirely sufficient in all ordinary practice. Analyses are so often misleading in sewage purification work, especially when published for advertising purposes, that one may well grow wary of them. The enthusiasm which leads the designing engineer to look with hopeful assurance upon his newly created work seems to infect with the same optimism the judgment of those who publish analyses showing the work of purification. Too often is it the fact that very large inferences are drawn from exceedingly slender data and among those whose knowledge of the subject is slight or superficial, widespread misrepresentation often results. About four years ago, while studying sewage purification for a city of considerable size, attention was attracted to some exceptionally good results produced by a novel plant, analyses of the effluent from which were reported in the engineering press. A journey followed as the result of the article, and when the Mecca was reached the odor from the plant could be detected perhaps a half-mile away. It was a severe lesson, but an efficient one, and since that time analyses, unless frequently made, long continued and well certified, have lost their weight and influence with the writer.

Percentages.—Another of the fallacies which often deceive the student of sewage purification work is the determination of the results from any given plant in percentages of organic matter removed. A plant is reported as removing 99.99 per cent. of the organic matter in the original sewage. This naturally seems to be excellent work. Another plant is reported as removing but 80 per cent. of the organic matter, which according to the point of view may or may not be supposedly poor. As a matter of fact, the 80 per cent. plant may actually be doing a great deal better work than the 99.99 per cent. plant. The fallacy lies in this: it is comparatively an easy matter to obtain large percentages of removal from a strongly concentrated sewage, while it is an exceedingly difficult matter to obtain such a large percentage from a very dilute sewage. It may be possible that the removal of 80 per cent. of organic matter from a very slightly polluted water may produce an effluent which is relatively much purer than the effluent from the plant removing the 99.99 per cent. of organic matter from a very thick concentrated sewage. It is, therefore, always necessary to know the relative strength of the original sewage before deciding from percentage figures that a plant is doing very high-class service.

Contact Beds.—A great deal has been written on the proper management of contact beds, especially from English sources. Presumably we are in possession of many of the facts necessary to successfully operate contact beds, and it must be admitted that so far a good deal of the information is derived from the working of full-sized plants, and is well demonstrated. There are, however, many things about the working of such plants which may be profitably investigated. It may, first of all, be pointed out that arbitrary lengths of time for the sewage to remain in contact with the grain of the contact filter is not in accordance with what we know of the fluctuations in the character of the sewage. The fineness of the grain of the filter, the character of the liquid to be treated, the amount and fineness of the suspended matter which it carries, the temperature of the air and of the sewage all must reasonably be expected to have some bearing on the length of time which the sewage is kept in contact, and yet almost every automatic device now available fixes the time of contact by the quantity of inflow. The rate of inflow may and usually does vary within wide limits and in a way which may be quite different from the operator's ideas of the correct contact period required. Indeed, as usually operated, there is no chance at all for experiment as to what the correct contact period should be in any particular case. It is as evident here as it is with the septic tank that if the proper and most efficient contact period for any given strength of sewage, temperature of air or



Automatic Controlling Device, Sewage Purification Plant, Lake Forest, Ill.

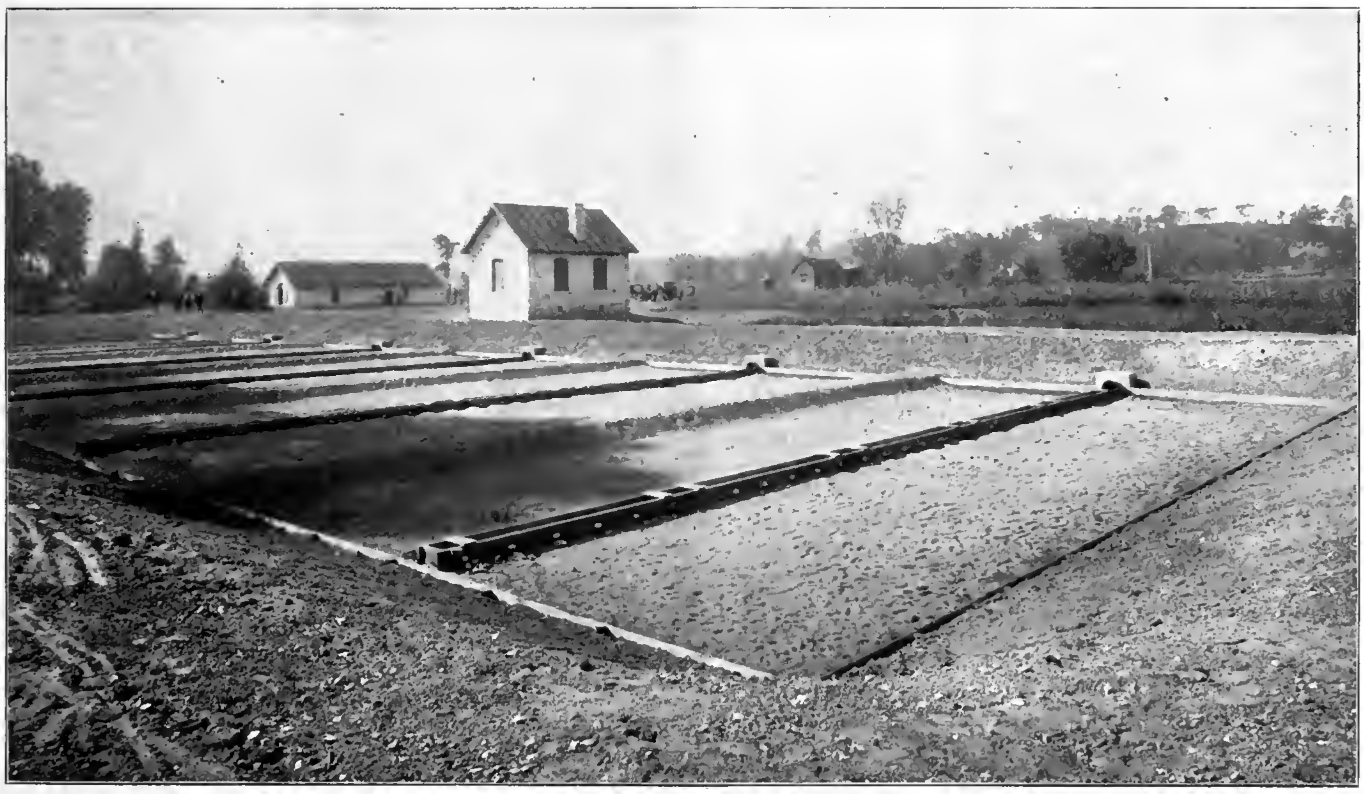
liquid, and fineness of grain could be experimentally determined, the efficiency of the plant might be largely increased. There is room for great improvement over present methods of control.

Leakage.—One of the minor difficulties in the operation of contact beds in the smaller plants is the question of leakage. A slight leakage of the valves of the automatic device, or of the contact bed itself, is generally sufficient to greatly retard the contact period, and even altogether defeat the operation of the beds. An engineer cannot be too careful in superintending the construction to be certain that the contact bed is thoroughly water-tight before putting in the contact material. The best form of automatic device for preventing leakage seems to be that which relies upon an air cushion for opening and shutting off flow. Ordinary valves will often either work very stiffly after a while and finally stop the automatic device from working at all, or else will be so loose and leaky as to allow a large portion of the incoming flow to escape before the bed is filled.

Supervision.—In installing automatic devices of any kind, and making recommendations for their management, it is a great mistake to assume that they do not need some supervision. Much has been expected in the practical operation of sewage purification plants from the many automatic features which have recently been introduced. It has been thought that with the newer biolytic processes supplemented by automatic devices for intermittent filtration or double contact work little or no annual operating expense would result. That this is true must not be denied, and that it does and will result in a larger adoption of sewage purification processes in the near future is certain; but it must be pointed out that there is a great danger in going from one extreme to the other, and for the designing engineer to intimate to the city authorities that he is about to give them an automatic plant which will require no renewals and which will practically run itself year in and year out, is at once to create the impression that no expense at all will be necessary, and that the city is purchasing something which can be put off in the most remote ravine adapted to the purpose and there left to be forgotten by everyone connected with municipal responsibilities. No plant, however automatic it may be, however perfect its appliances for preventing manual labor can be left alone, unless possibly one might except the small plants for household service.

Intermittent Filtration.—In the operation of plants consisting of septic tanks followed by intermittent filtration as a second stage, great gains have been made by the introduction of automatic devices by which the effluent from the septic tank may be rotated on to the intermittent filtration beds. Such devices are operated by the falling sewage. This not only dispenses with the services of a man who must divert the flow day by day, but makes the action of the beds much more regular and systematic, eliminating the contingencies of night, Sundays and holidays, which would naturally prevent uniformity in operation by hand. Then, too, the greatly lessened area of filter bed required for septic tank effluent means that there is the necessity for much more rapid diversion of the sewage from one bed to another than was formerly the case in intermittent filtration practice, and this almost puts it out of the question to employ manual labor for this purpose. Nowhere is the necessity for careful regulation of the septic tank more evident than it is in a plant of this character. If the septic tank effluent is filled with suspended matter, even finely divided, and the sand of the bed is of fine grain, very careful management is necessary.

Lake Forest, Ill.—The Lake Forest plant, which has been under the writer's supervision during the past year, consists of a septic tank of about 50,000 gallons capacity divided into five compartments. The tank is neither light- nor air-tight. It has no patent arrangements for inlet or outlet, and is an open tank housed over with a light structure giving ample ventilation and opportunity for inspection, while preventing the hot sun of summer or the cold winds of winter from varying the temperature of the sewage to any unusual degree. After leaving the septic tank the sewage passes into a dosing chamber holding 7,000 gallons of liquid, and by means of an automatic device operated by the falling liquid, it is delivered in rotation on to ten intermittent sand filters consisting of the natural sand of the beach of Lake Michigan as found in place. The beds are of 3,200 square feet area each. At present these beds are working at the rate of 300,000 gallons per acre per day, their total area being ¾ acre. This sand is quite fine; 85 per cent. passing a sieve of 40 mesh, 42 per cent. passing 60 mesh to the inch. In practical operation it has been found that unless the septic tank was working at a maximum of efficiency, finely divided suspended matter coming over from the tank, would, in the course of time, seal the surface of the filters and render it necessary to hand-harrow them after the application of five or six doses. As each bed receives about two doses a day, this meant that the total area would have to be raked over twice a week. In the early operation of the plant the man in charge, failing to rake the beds at all, reported that there must be something the matter with the under drains as the sewage would not go through the beds. A visit to the plant at once revealed that the difficulty was due to negligence, and a little application of the rake soon broke up the surface skin and put the beds in normal shape again. Later, after the septic tank was better regulated, much less suspended matter came over on to the filters, and a great improvement was seen in the amount of care which the beds had to receive. With fine sand used at this plant, it is probable that there will always be from ten to twelve hours of labor per week necessary to keep the beds in good condition. The septic tank is now operating with 6½ hours rest period, the longest of any of the plants under notice, the sewage being thick and concentrated. The tank has not been cleaned during the year and no perceptible deposit has occurred.



Septic Tank. Controlling Chamber. Filter Beds.

SEWAGE PURIFICATION PLANT, WAUWATOSA, WIS.

Wauwatosa, Wis.—The Wauwatosa plant is constructed on the same lines as the Lake Forest plant. A septic tank holding 40,000 gallons of sewage, operated on the five compartment system, was constructed of concrete and covered with a plain brick house. The effluent is delivered to a dosing chamber in a separate structure containing about 6,000 gallons, which by an automatic device is delivered in rotation on to six filtration beds about $3\frac{1}{2}$ feet in depth. The sand of which these beds are composed is much coarser than that used in the Lake Forest plant, consequently it has not needed so much attention. One hand harrowing each week for each bed has kept the plant up to its maximum efficiency, and the effluent is clear and odorless after being kept in close stoppered bottles for several days. The automatic device has been satisfactory and has operated without stoppage for over a year. The tank is operated with about four hours' rest period, and with the exception of removal of surface scum once or twice has not needed cleaning. The filter beds are operating at the rate of 300,000 gallons per acre per day, but when high water prevails in the river they are discontinued. The sewage is growing stronger. The plant has been in competent hands from the very beginning, and is excellently managed.

Holland, Mich.—Two septic tanks at Holland, Mich., have been in operation over one year. The effluent is emptied into Black Lake. The sewage is not strong as the sewer system is not yet extensive, but the tanks are exercising a marked improvement on the impurities, and so far have kept free from deposit. The main tank is constructed with three compartments, and has a rest period at present of about two hours. The plant is not closely watched.

Glen View, Ill.—This plant originally constructed in 1898 has not been under the writer's observation for two years. One year it was entirely neglected. The last season it has had some attention. The septic tank is only a single compartment and the secondary stage consists of contact beds of coke. The writer is informed that during the past season these contact beds have been successfully operated as continuous filters. About 10,000 gallons of very concentrated sewage a day is cared for. When the plant is supervised the effluent is good. The tank has had to be cleaned at least once every year, and one year (1899) it was cleaned four times.

Princeton, Ill.—A 60,000 gallon septic tank has been in operation about one year. It is built on the five compartment system and housed over. It does not receive special attention, but good results are reported. If so, they are probably accidental. It has never been cleaned, but some deposit on the bottom is reported. The rest period is not known. The plant was designed with intermittent filtration as a secondary stage, but the city is now hoping that the first stage will be sufficient to avoid nuisance.

Danville, Ky.—Three septic tanks have been in operation here over one year. The largest is of 40,000 gallons capacity, and is followed by intermittent subsoil filtration. It is reported to be working well, but receives no special attention. It is perhaps too early to draw conclusions concerning it. It has not required cleaning as yet.

Highland Park, Ill.—A small septic tank has been in operation on the West district for two years. It has received no attention whatever and has caused no complaint as yet; it has never been cleaned. It is said not to be unduly filled with deposit. The effluent is reported as good, but the sewage it receives is not strong. It is noticed as a matter of experience that weak or thin sewage is not generally exacting in its treatment.

An Analysis of the Commercial Value of a Water-Power.

Slightly condensed from a paper by A. F. Nagle before the American Society of Mechanical Engineers.

The writer recently testified in court as to the value of water-power per horse-power per annum in a manner that may be of interest to our membership. The subject-matter has been discussed heretofore in our society, but I am not aware that precisely the same analysis has been given before. The problem is quite a familiar one to New England engineers. The river-flow is assured to certain abutting parties by old legislative grants, and is usually used for power purposes. Any town or city taking water from this stream is liable for damages incurred by reducing the available power of said stream of water. The amount of power existing in the stream at each mill, expressed in horse-power per second, as well as the amount taken, or diverted, by the city, and affecting the particular mills, is a problem for hydraulic engineers which I do not take up; but the value of the water-power at each mill is a problem which I have attempted to solve. I have formulated my studies under three theorems, which I believe express the true principles under which the problem can be solved with as much certainty as the cost of a steam-power.

any analysis that may be applied to the problem under consideration.

The annual cost of steam-power per horse-power, including every item except land, can be calculated by an experienced engineer for any particular locality with reasonable accuracy. In Tables I. and II. I have given my estimates of engine plants ranging from 50 horse-power to 500 horse-power, single-condensing engines; and from 400 horse-power to 1,500 horse-power compound-condensing engines located along the Blackstone River, New England. These estimates are generally large, but as the items appear both in the minuend and subtrahend of the calculation, the remainder, resulting in the value of the water-power, is not so seriously affected thereby. The result, however, of these larger figures for steam-power is to increase the value of the water-power. The items comprising the tables are all so well known to engineers that it is needless for me to comment upon them. Nor is it so much my purpose to establish the accuracy of these particular items, or their results, as it is to establish a principle, or method, of calculating the value of a water-power for power purposes, and thereby take the problem out of the domain of prejudiced guesswork.

Table I.—Annual Cost of Steam-power per Indicated Horse-power.—Compound Condensing Engine.

Horse-power.	400	500	600	700	800	900	1,000	1,200	1,500
Cost of plant per I.H.P.	$64.00	$60.00	$57.50	$56.00	$55.50	$55.00	$54.60	$54.00	$53.00
Annual interest, etc., at 10 p. c. per I.H.P.	6.40	6.00	5.75	5.60	5.55	5.50	5.46	5.40	5.30
Cost of banking (no heating) repairs, supplies, engineer, etc., per I.H.P.	7.30	7.60	7.75	7.80	7.95	7.70	7.55	7.50	7.50
Annual (3,060 hrs.) cost of coal at $4.50 per long ton per I.H.P.	12.30	11.40	10.50	9.85	9.50	9.30	9.25	9.25	9.20
Total annual cost per I.H.P.	26.00	25.00	24.00	23.25	23.00	22.50	22.26	22.15	22.00

Table II.—Annual Cost of Steam-power per Indicated Horse-power.—Simple Condensing Engine.

Horse-power.	50	75	100	150	200	250	300	400	500
Cost of plant per I.H.P.	$90.00	$75.00	$65.00	$57.00	$51.00	$47.00	$45.00	$43.00	$42.00
Annual interest, etc., at 10 p. c. per I.H.P.	9.00	7.50	6.50	5.70	5.10	4.70	4.50	4.30	4.20
Cost of banking (no heating) repairs, supplies, engineer, etc., per I.H.P.	9.00	8.50	8.20	8.30	8.60	8.30	7.90	7.85	7.80
Annual (3,060 hrs.) cost of coal at $4.50 per long ton per I.H.P.	25.00	22.00	20.00	17.00	15.30	15.00	14.60	13.85	13.00
Total annual cost per I.H.P.	43.00	38.00	34.70	31.00	29.00	28 00	27.00	26.00	25.00

Theorem 1. The value of water-power, when of ample capacity for a specific purpose, does not exceed the cost of what a competing power, steam or gas engine, can be installed and operated for at the same locality.

Theorem 2. When a water-power is insufficient for a specific purpose, due to the varying flow at different seasons of the year, and its limited amount, then its value is reduced from that established by Theorem 1, by the cost of installing and operating a steam plant to make good this insufficiency.

Theorem 3. The damages to be paid annually, or capitalized at — per cent. if made in one payment, for a given amount of diverted water-power is the value of the water-power as found by Theorem 2, plus the depreciation in the value of the remaining water-power.

The cost of power is an element in all productive industries, and whether it be a large or small element, the mill (we will call it) demands a certain amount of power, the cost of which, if a steam plant, can be calculated quite closely, probably within 10 per cent. It is the interest of the mill owner to obtain his power at the least possible cost to himself, and he stands in the position of a buyer of power before the power-producing public. Two sellers may offer him power—a steam-power producer, or a water-power producer. Because the mill owner in New England is generally also a water-power owner, does not change the relation of the power consumer to the power producer, a buyer and a seller, and for a clear understanding of this complex problem, it is absolutely necessary to separate the two parties in

Theorem 1 is almost a self-evident proposition. No mill owner as a buyer of power will pay more for water-power than he can install and operate a steam plant for. He would not even give as much as that, because if he had water-power only, he would have to install a boiler plant for heating and other auxiliary uses; while if he had a steam plant, he could supply himself with this additional steam at a comparatively small cost. For present purposes, however, I shall neglect this fact.

Theorem 2 is not quite so obvious. Very few water-powers are of sufficient power to supply the large mills they drive with ample power every day in the year. At times there is an excess, and at other times it is quite insufficient. It is at this point that a clear understanding must be had of the relation of the mill owner to the water-power owner. It is not the business of the mill owner to meddle with the problem of this varying and insufficient water supply. That difficulty belongs entirely to the water-power owner. In order to make the water-power commercially available, in order to give it any value at all to the purchaser of power, in order to give it what it has been pleased to call "a market value," "a commercial value," he must supplement the fluctuating water-power with steam-power. The maximum possible price obtainable for the combined steam and water-power has been fixed by the cost of a single steam plant. Hence the less the steam-power costs him the more he will get for his water-power. This will be more fully illustrated by detailed calculations hereafter.

Theorem 3. This theorem is perhaps more theoretical than practical, for in few cases is the quantity of water diverted from a stream sufficiently large to affect perceptibly the quantity remaining. It is, however, a fact that repeated diversions constantly diminish the value of the remaining power; and it is proper that this depreciation of the remaining power should be paid for at each diversion. This would seem to be a principle of equity, and I have investigated the application to a particular case upon a rather extravagant hypothesis.

To illustrate the practical application of the theorems here advanced, one mill and its power diagram has been selected from the testimony in the suit. The river flow in horse-power per minute for every month in the year is established at the mill by the hydraulic engineers employed in the suit. The amount of the diverted power at the mill is also given by said engineers, but is too small to appear in the diagram, Fig. 1. The amount of power required to operate the mill, and the wheel capacity, are given by the mill owner. Referring to Fig. 1, the power of the river flow is seen to vary greatly. This mill requires an average of 900 horse-power per annum. The water wheel is of only 743 horse-power, and the mean annual

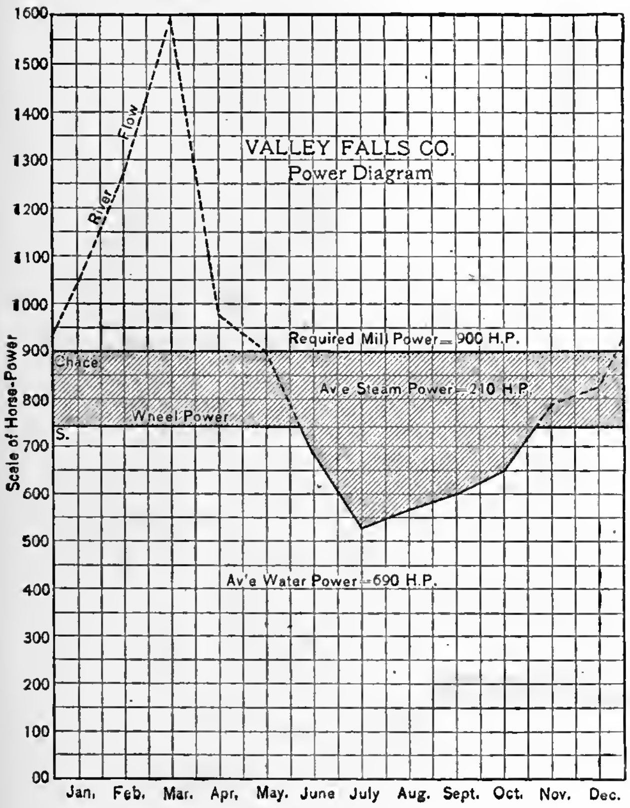


FIGURE 1.

water-power is 690 horse-power, requiring a steam-power of 210 horse-power to give the 900 horse-power to the mill. The low stage of the river is such that a 370 horse-power steam plant will be required at times.

Table III.—Valley Falls Company.

Required mill-power	900 H.-P.	
Average water-power	690 "	
Average steam-power	210 "	
Maximum steam-power	370 "	
Time engine runs	12 months	
Full annual cost of 900 H.-P.C.C. plant at $22.50		$20,250
Annual interest, etc., 370 H.-P.S.C. at $4.40	$1,628	
Annual supplies, etc., 370 H.-P.S.C. at $7.85	2,904	
Annual coal, 210 H.-P.S.C. at $14.00	2,940	
Total cost of 210 H.-P. steam	$7,472	7,472
Cost per H.-P.	35.60	
Value of 690 H.-P. water		$12,778
Value of 1 H.-P. water	$18.52	

Maximum Efficiency of a Water-power Plant.—Referring again to Fig. 1, it is quite evident that a larger wheel-power would have been conducive to a greater value of the water-power. For the purpose of ascertaining the greatest value of a water-power by the rules laid down in this paper, let us assume that the minimum flow is as shown in the figure. In that case water of 530 horse-power would be supplied every day in the year, and if it could be brought about that a mill required just that amount of power, the water-power would be worth $25 per horse-power (see Table I.), and the water owner would receive a revenue of $13,250 per annum. On the other hand, if the mill still required 900 horse-power, and only 530 horse-power wheel-power were available, then the calculation would stand as in Table IV.

Table IV.

Required mill-power	900 H.-P.	
Average water-power	530 "	
Average steam-power and maximum	370 "	
Full annual cost of 900 H.-P.C.C. plant at $22.50		$20,250
Annual interest, etc., 370 H.-P.S.C. at $4.40	$1,628	
Annual supplies, etc., 370 H.-P.S.C. at $7.85	2,904	
Annual coal, 370 H.-P.S.C. at $14.00	5,180	
Total cost of 370 H.-P. steam	$9,612	9,612
Cost per H.-P.	26.00	
Value of 530 H.-P. water		10,538
Value of 1 H.-P. water	$19.88	

Now let us go a step further, and under the same conditions and requirements put in a 900-horse-power-wheel. Then the calculations will stand as in Table V.

Table V.

Required mill-power	900 H.-P.	
Average water-power	764 "	
Average steam-power	136 "	
Maximum steam-power	370 "	
Time engine runs	7½ months	
Full annual cost of 900 H.-P.C.C. plant at $22.50		$20,250
Annual interest, etc., 370 H.-P.S.C. at $4.40	$1,628	
7½ mos.' supplies, etc., 370 H.-P.S.C. at $7.85	1,815	
Annual coal 136 H.-P.S.C. at $14.00	1,904	
Total cost of 136 H.-P. steam	$5,347	5,347
Cost per H.-P.	39.32	
Value of 764 H.-P. water		14,903
Value of 1 H.-P. water	$19.54	

Hence, we see that a mill requiring 900 horse-power with a river flow as indicated by Fig. 1, can be supplied with power by a water-power owner in one of two extreme ways. If he puts in only 530 horse-power wheels running every day in the year at this power, he will receive $10,538 net for his water, but he must spend $9,612 for steam-power in order to obtain this amount for his water. If, on the other hand, he would put in a 900-horse-power wheel and spend $5,347 for steam, albeit it costs at the rate of nearly $40 per horse-power, he will receive nearly $15,000 per annum, or $19.54 per horse-power.

Monthly versus Annual Averages.—There is some question as to the accuracy of determining the average annual value of the water-power by the annual average, or calculating it separately for each month in the year. I have made an estimate of said values as applied to Fig. 1, by monthly estimates, and compared it with the annual average which has been used throughout these calculations. I have also introduced a corrected value of coal due to underloading of the engine, and embodied the result in Table VI. Column 1, Table VI., is the average monthly steam-power, column 2 is the cost of this steam-power as found by preceding methods, column 3 is the corrected cost of coal per annum for an underloaded engine, column 4 is the annual cost of steam-power based upon coal value in column 3, and column 5 is the final value of water-power based upon steam cost in column 4.

Table VI.

Power required at mill....................900 H.-P.
Cost of steam, H.-P. per annum.......... $22.50
Cost of coal per H.-P. per annum.......... 9.30

Monthly H.-P.	Cost of steam per H.-P. uncorrected.	Cost of coal per H.-P. corrected for underload.	Cost of steam per H.-P. corrected.	Value of water per H.-P. based upon Col. 4.
160	$42.32	$17.50	$45.82	$17.47
160	42.32	17.50	45.82	17.47
160	42.32	17.50	45.82	17.47
160	42.32	17.50	45.82	17.47
160	42.32	17.50	45.82	17.47
220	34.60	16.00	36.62	17.94
350	27.00	14.00	27.00	19.67
330	27.73	14.00	27.73	19.47
300	29.11	14.50	29.61	18.95
240	32.89	15.50	34.38	18.18
160	42.32	17.50	45.82	17.47
160	42.32	17.50	45.82	17.47
210	37.30	16.38	39.67	*18.04
210	35.60	14.00	....	†18.52

*Annual average by monthly estimate. †Annual average by yearly estimate.

It will be seen that while the cost of steam-power (210 horse-power) based upon a yearly average is $35.60 per horse-power, it is increased to $37.30 per horse-power if made upon a monthly basis; and if also corrected for coal, becomes $39.67 per horse-power; and the value of water-power is reduced from $18.52 to $18.04, which is less than one would have supposed it to have been, and yet it is the correct way to pursue.

Successive Diversions.—The amount of water diverted is usually very small in proportion to the total quantity in the river. To illustrate in detail the manner of calculating the value of the water-power per horse-power per annum when large quantities of water are taken at several intervals instead of all at one time, I have applied the calculation to a water privilege substantially like that of the Valley Falls Company, Fig. 1, where, say, 100 horse-power is taken at each interval, until it is all taken. The results are given in Table VII.

Table VII.—First Case, Original Condition.

Required mill-power	900 H.-P.	
Average water-power	700 "	
Average steam-power	200 "	
Maximum steam-power	400 "	
Time engine runs	12 mos. always	
Full annual cost of 900 H.-P.C.C. at $22.50		$20,250
Annual interest, etc., 400 H.-P.C.C. at $6.40	$2,560	
Annual supplies, etc., 400 H.-P.C.C. at $7.30	2,920	
Annual coal, 200 H.-P.C.C. at $12.30	2,460	
Total cost of 200 H.-P. steam	$7,940	7,940
Cost per H.-P.	39.70	
Value of 700 H.-P. water		12,310
Value of 1 H.-P. water	$17.60	

Second Case.

Required mill-power	900 H.-P.	
Average water-power	600 "	
Average steam-power	300 "	
Maximum steam-power	500 "	
Full annual cost of 900 H.-P. as before		$20,250
Annual interest, etc., 500 H.-P.C.C. at $6.00	$3,000	
Annual supplies, etc., 500 H.-P.C.C. at $7.60	3,800	
Annual coal, 300 H.-P.C.C. at $11.40	3,420	
Total cost of 300 H.-P. steam	$10,220	10,220
Cost per H.-P.	34.07	
Value of 600 H.-P. water		10,030
Value of 1 H.-P. water	$16.72	

Third Case.

Required mill-power	900 H.-P.	
Average water-power	500 "	
Average steam-power	400 "	
Maximum steam-power	600 "	
Full annual cost of 900 H.-P. as before		$20,250
Annual interest, etc., 600 H.-P.C.C. at $5.75	$3,450	
Annual supplies, etc., 600 H.-P.C.C. at $7.75	4,650	
Annual coal, 400 H.-P.C.C. at $10.50	4,200	
Total cost of 400 H.-P. steam	$12,300	12,300
Cost per H.-P.	30.75	
Value of 500 H.-P. water		7,950
Value of 1 H.-P. water	$15.90	

A summary of cost of steam-power and value of water-power at seven successive diversions, the required mill-power remaining at 900 horse-power, is given in Table VIII.

Table VIII.

Cost of Steam-power.			Value of Water-power.		
Amount.	Per H.-P. annual.	Total cost.	Amount.	Per H.-P. annual.	Total value.
1	2	3	4	5	6
200 H.-P.	$39.70	$7,940	700 H.-P.	$17.60	$12,310
300 "	34.07	10,220	600 "	16.72	10,030
400 "	30.75	12,300	500 "	15.90	7,950
500 "	28.61	14,305	400 "	14.86	5,945
600 "	27.50	16,500	300 "	12.50	3,750
700 "	26.27	18,390	200 "	9.30	1,860
800 "	24.10	19,320	100 "	9.30	930
900 "	22.50	20,250	0 "	...	...

In addition to the value of the diverted water-power, there is also a depreciated value to the remaining water-power. This is easily found by finding the value of the water-power before and after diversion, and the difference between the two, multiplied by the amount remaining, is the amount to be paid for depreciation. Table IX. gives these amounts, as well as the direct damages for 100 horse-power diverted at seven intervals.

Table IX.—Annual Cost of 100 H.-P. Diverted Successively, and Depreciation of Remaining power for Seven Periods. Required Mill-power Always 900 H.-P. Cost Thereof at \$22.50 = \$20,250 per Annum.

Amount of water-power. 1	Value of water per H.-P. 2	Difference. 3	Cost of 100 H.-P. 4	Water-power remaining. 5	Amount of depreciation. 6	Total Cols. 4 and 6. 7	Cumulative amount. 8
700 H.-P.	\$17.60	0.88	\$1,760	600 H.-P.	\$528	\$2,288	\$2,288
600 "	16.72	0.82	1,672	500 "	410	2,082	4,370
500 "	15.90	1.04	1,590	400 "	416	2,006	6,376
400 "	14.86	2.36	1,486	300 "	708	2,194	8,570
300 "	12.50	3.20	1,250	200 "	640	1,890	10,460
200 "	9.30	0.	930	100 "	...	930	11,390
100 "	9.30	...	930	...	...	930	12,320
Total.......	...	...	\$9,618	...	\$2,702	\$12,320	...

The accounts of the water-power owner will, therefore, stand as in Table X.

Table X.

Receives annually from the mill owner for 900 H.-P.	\$20,250
Before any water is taken, expends annually for steam-power (Table VIII, Column 3)..	7,940
Leaving a net income of	\$12,310
1st—When 100 H.-P. are taken at \$17.60 plus depreciation, receives from mill owner....	\$20,250
100 H.-P.—From city (Table IX, Column 8)	2,288
A total income of	\$22,538
Expends for steam-power (Table VIII, Col. 3)	10,220
Net income	\$12,318
2d—Second diversion at \$16.70 plus depreciation, receives from mill owner	\$20,250
100 H.-P.—From city (\$2,288 + \$2,082)...	4,370
A total income of	\$24,620
Expends for steam (Table VIII, Column 3)..	12,300
Net income of	\$12,320
3d—From mill owner	\$20,250
From city	6,376
100 H.-P.—Total income of	\$26,626
Cost of steam as above	14,305
Net income	\$12,321

It will be seen that the analysis proves itself correct in every instance. The water-power owner, whose income was \$12,320 per annum before any diversion of water took place always receives the same figure, whether much or little, or all be taken, at intervals, or all at one time.

It is sometimes admitted by engineers on the other side that my analysis for ascertaining the value of water-power may be correct, but that diverted water-power must be paid for at what it costs to take its place. Thus the value of the water-power is \$18.52, but the cost of its auxiliary steam-power is \$35.60 per horse-power, and they would thus maintain that that should be the amount to be paid for diverted power. This seems very plausible, and it is a fallacy not easily seen through by engineers, attorneys, or courts; but it is a fallacy nevertheless. It is a fallacy, in the first place, because if the theory were correct, it would lead to absurd conclusions. Thus, if the entire water-power of 690 horse-power were taken and paid for at the rate of the cost of its auxiliary steam-power, namely, \$35.60, the damages would be \$24,564, which exceeds the cost of an entire 900-horse-power steam plant.

It is fallacious, in the second place, because it makes the damages to an imperfect or insufficient water-power greater than is conceded to be the value of a perfect or complete one; that is, it is claimed that \$35.60 per horse-power should be paid for a defective water-power when \$22.50 per horse-power will pay for a perfect power.

It were perhaps better for a clearer understanding of this problem if the cost of furnishing the auxiliary steam-power were not reduced to its equivalent cost per horse-power at all, and simply to say that it costs the water-power owner so much money to supply the natural defects of his water-power, which expense he must go to in order to find a market for his water-power. The question of cost of steam-power is only entered into in order to ascertain the true value of the water-power, and it is the interest of the water-power owner to make it as little as possible. As a matter of fact, for the small diverted power, it costs him only the price of coal, say \$14 per horse-power per annum, while he is paid, under this analysis \$18.52 per horse-power. It is held, however, that if he is paid only for the coal consumed, he is paid nothing for his plant, etc., and that the defendant has no right to use that plant.

The maintenance of this auxiliary steam plant is a necessity and a burden entirely upon the shoulders of the water-power owner, in order to make his water-power worth its maximum to himself, and that maximum value of water-power the defendant is willing to pay.

Two causes are at work which make this auxiliary steam-power disproportionately expensive: First, the natural fluctuation of the river flow; and, second, its insufficiency for the uses of the mill. Neither of these causes are the fault of the defendant, except in the latter case, by the amount of diversion. It is not the fault of the defendant that the auxiliary power costs what it does, and he should, therefore, not be made to pay for it. When he has paid the market or commercial value of the water-power, plus the damage inflicted upon the balance of remaining power, he has met the requirements of equity.

En passant I may allude to the favorite illustration of eminent counsel, that if a man brings into the city horses which he is selling for \$100 apiece, and the city takes for its own use one or more of his horses, the city must pay \$100 for the horses taken, and not \$50 or so, or whatever they may cost him. I agree to the correctness of the claim of the plaintiff. On the other hand, the plaintiff attempts to establish the market value of steam-power by asking a tenant at some city factory what he pays for power. The case of a tenant at a distance from the source of power, and in small amounts, is not an analogous case with the one with water-power at a mill. Here the entire water-power is absorbed by one purchaser, and in order to give the entire water-power its maximum commercial value, an incidental expense is necessary, with which the defendant really has no concern.

Theorem 3 expresses the true basis upon which damages should be paid. Under the analysis here laid down the water-power owner is not injured one dollar whether much or little water be taken, for he is assured precisely the same annual income he received before the city trespassed upon his rights as after. In the suit referred to, however, the amount of power diverted is so small compared with the river flow or total mill power that I neglected to compute this item.

The Elevated and Subway street railways of New York have been brought under one control by the combination of the Manhattan Elevated Railway Company with the Interborough Rapid Transit Company.

The Engine Builders Association of the United States held its annual meeting in New York City, at Sherry's, December 1 and 2. Professional papers were presented by Mr. Ernest Foster on "Superheated Steam," by Mr. William Andrews on "High Pressure Steam Piping," by Mr. George R. Phillips upon "The Early History of the Corliss Engine" and by Prof. John E. Sweet upon "The History of the High Speed Engine." On the second day in executive session for members only reports of committees and various business matters were taken up. In the evening the annual dinner was held.

Letter to the Editor.

Rockwood Compound Engines.

Sir: In the issue of The Engineering Record for Nov. 22 may be found some data of a triple expansion engine test made by Prof. Hollis. The conditions under which this engine is working are not fully stated, but enough is said to invite comparison between its performance and that of the Atlantic Mills compound engine tested by Mr. Barrus. (Eng. Rec. Nov. 8.)

The boiler pressure and load were in each case nearly the same. A slight superheat to the steam of the compound was offset by the increase of the pressure of the steam supplied to the triple expansion engine. The best performance of the compound was 2 per cent. better than that of the triple. The actual figures were as follows:

Triple expansion engine...11.47 lbs. per I.H.P. per hr.
Compound engine.........11.22 lbs. per I.H.P. per hr.

If these facts had been placed before the engineering public even ten years ago what a sensation would have been created, not to mention doubts of the validity of both tests which would have been freely expressed. It is ten years since the first test of a Rockwood compound engine was published, and at that time it was freely doubted. But at that time no such engine had the advantage of an adequate boiler pressure. The best result obtainable was 12.8 pounds of steam per I. H. P. per hour. The saving of 14 per cent. is due to the higher pressure and slight superheat of the steam in the present instance. It should be noted, however, that this engine is the first one to have Corliss valves. All the others were Wheelock engines. It may be noted that the Wheelock valve gives very much less clearance for the same port areas than the Corliss valve. On the other hand, the Wheelock valve has much more superficial area upon which condensation may take place. The practical question probably is: Which form of valve remains tight without scraping for the longest period of time? Prof. Hollis thinks it is the gridiron, while many others will doubtless hold the contrary view.

The two cylinder engine for stationary purposes has so many practical advantages over the triple expansion engine that its great economy when working under high boiler pressure and a large ratio of expansion and considerable "drop" in the receiver should be more generally realized.

Yours truly,

George I. Rockwood.

Worcester, Mass., Nov. 25.

Systematic Water-Waste Detection was begun at King's Lynn, England, a town of about 20,000 inhabitants, in 1899, under the direction of the engineer, Mr. H. J. Weaver. Thirteen 6-inch Deacon waste-detection meters were set and the town divided into districts, each governed by a meter. Stopcocks were fixed on every service, and valves were so arranged on the mains as to command each street and section of district. Two night and two day inspectors were appointed, the duty of the former being to make the night inspections with a stethoscope, and report to the day inspectors, who visited the houses. The number of inspectors has now been reduced to one, who acts as night inspector, the foreman of the water-works department taking care of the rest of the work. As a result of this plan, the consumption has been reduced from 69 U. S. gallons per head per day to 44.4. The minimum limit of proper consumption for this town, where a large amount is required for sewer flushing and for other than domestic purposes, is considered by Mr. Weaver to be in the neighborhood of 35 U. S. gallons per head per day.

Water Supply for the Ansonia Swimming Bath.

The Ansonia Apartment hotel is a very large 17-story building at Broadway and 73rd Street, New York, which has been fitted with extensive and elaborate sanitary, mechanical and hydraulic installations. The general system and details for the supply and distribution of over 80,000,000 gallons of water a year, and the steam, heating and mechanical plants were illustrated in The Engineering Record of November 1st and 15th respectively. These articles describe both the general conditions of operating the elaborate plant, and its special relations to the delivery, removal and economical use of the large quantity of water required for the swimming bath, the details of which are here described.

The Ansonia has an estimated tenancy of about 1,300 persons, and besides the water supplies to its public and private restaurants and dining rooms, its general hot and cold water distribution systems, refrigerated water circulation and private bath rooms, there is planned a complete system of Turkish and Russian baths and an immense swimming tank in the sub-basement. The latter is to be abundantly supplied with hot and cold water by a system which will not only keep up a constant circulation and insure clean bathing water but which is arranged so that the water will be successively used for several purposes and so designed as to make a liberal demand for water in the swimming baths promote the efficiency of the mechanical installations and reduce, rather than increase, the operating expenses of the establishment.

The swimming bath is about 86 feet long, 33 feet wide and 11 feet deep, in maximum dimensions, and has reinforced concrete walls and floor built in an excavation in solid rock below the sub-basement floor. It has, as shown in the general diagram, rounded ends and straight sides with inside projections made to enclose columns which are located at one end. The concrete has an average thickness of about 2 feet and is reinforced by overlapping sheets of expanded metal embedded in all parts of it parallel with the surface. Close to the outer surfaces of the concrete there is also embedded a waterproof course of several thicknesses of tar paper and hot asphalt, continuous over the whole exterior of the bath, and its upper edges have a white marble coping. The bath is lined with white glazed bricks. It is accessible by three flights of stairs with white marble tread and riser slabs bedded in the solid concrete. Twelve of the square cast-iron columns supporting the building are located in the walls of the bath, which are widened to receive them, and are carried down through the concrete to footings on the rock below, as shown in the detail section of the wall.

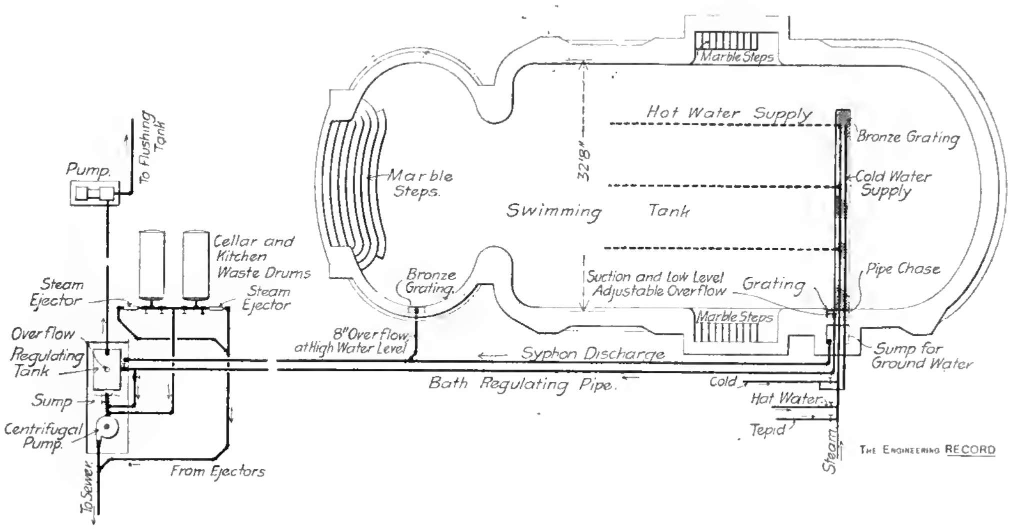
The bottom of the bath is curved, to make, in cross section, a flat arch fitting the concave excavation in the rock and intended to give additional strength to resist possible upward pressure from ground water. It is unlikely, however, that there will ever be any unbalanced upward pressure there for a sump has been excavated close to one end of the bath, to a depth below the bottom of the bath, in which the ground water freely collects and from which it is automatically ejected to the sewer. Adjacent to this sump well, but separated from it by a solid wall, is a vertical recess in the side wall of the bath through which the principal inlet and outlet pipes are carried to the bottom of the bath behind a removable bronze grill. The grill plate is made of ½-inch metal, countersunk screwed to the rebated face of two vertical bronze jamb plates. These are Z-shaped in cross section with horizontal inside ribs through which hook rods anchor them back to the concrete. The bath is enclosed by a railing, not shown in the drawings, with 2½-inch vertical posts extending through the coping and 18 inches into the concrete walls.

The bath has a depth to high water line of 9 feet 9 inches maximum, and a capacity of 23,000 cubic feet, or about 172,000 gallons. It requires about 3½ hours to fill the bath. It can be supplied with cold water directly from the street mains, with cold water heated by injection of live steam, with tepid water, with hot water, with hot water superheated by steam or with steam alone, injected into the water in the bottom of the bath. Normally the supply will be of hot or tepid water which has already been used in the refrigerating plant. All water supplied to the bath is filtered and that which is used first for refrigerating purposes is circulated around coils without being in any way exposed to contamination so that the whole supply is perfectly clean and fresh. Tepid water at a temperature of about 90 degrees is delivered through a 3-inch pipe from the closed absorber of the ice plant. Hot water at 110 to 120 degrees is delivered through a 3-inch pipe from the ammonia condenser, cold water is delivered through a 4-inch pipe and live or exhaust steam is delivered through a 1½-inch pipe.

All these pipes are connected to a header which may receive a single supply or be supplied from two or more sources at once. The header, as shown in the detail sketches and indicated in the general plan and section at C C, delivers into the 4-inch horizontal hot water pipe which is carried nearly across the bath in a floor trench covered with a removable bronze grill. This pipe is closed at the farther end and has three 2-inch horizontal branches, about 20 feet long, open at their extremities. Each branch passes through a stuffing box into a 4-inch brass jacket pipe which is closed at both ends and is bedded in the concrete floor of the bath about 5 inches below the finished surface. This pipe serves as a shell from which the 2-inch pipe can be easily removed if required, without disturbing the floor of the bath, and is also a distributing chamber which is filled from the inside pipe and discharges into the bath at several places. The outlets are small vertical brass nozzles, ½ inch in diameter, which are screwed in T's set about 24 inches apart on the 4-inch pipe, and having their tips just flush with the finished floor surface. By this arrangement water of any desired temperature between about 50 degrees and 120 degrees is injected into the bath through 30 nozzles distributed over the middle third of its area.

The 4-inch cold water supply pipe to the hot water header is valved and continued down the wall chase and across the bath floor in the trench beside the hot water pipe. It is perforated with ¼-inch holes 3 inches apart on the upper surface and is closed at the farther end. Ordinarily, warm or tepid water only will be supplied to the tank and its temperature will be maintained at about 66 degrees. The estimated daily supply is about 60,000 gallons all filtered. At the regular city rate of $1 per 1,000 cubic feet this would cost about $2,800 a year, and this sum, plus what it would cost to heat the water, is saved by using the water which has passed through the condenser and absorber. Besides this the cost of the water is doubly saved for the same water after being used in the swimming bath is refiltered and used for the flushing system in toilet rooms.

A fixed high water overflow is built in one wall of the bath and limits the height to which the water can rise, no matter how much water may carelessly be delivered through the hot and cold inlets after the bath is full. It has a brass box with a vertical bronze grating in the face of the wall just below the coping. The bottom of the box has a removable convex strainer covering the outlet to an 8-inch waste pipe which discharges to a sump, whence the water is periodically pumped into the sewer. Ordinarily this outlet is not used but the water overflows through a regulating pipe by which it is maintained at an adjustable lower level.



System of Pipes for Filling and Emptying Swimming Bath.

This is a 6-inch iron pipe, with its highest point about 24 inches below the high water overflow level, which rises from the bottom of the bath and runs alongside the inlet pipes in the wall chase and thence in a floor trench to the pump sump. This pipe is shown in the detail of the wall chase and supply pipes, but the location of the horizontal upper part of it is incorrectly shown too high.

This pipe, as long as the bath is filled within 2 feet of its maximum depth, is always full of water, and connects into a steel plate regulating tank set in the upper part of the pump sump with its upper edge a little above high water level in the bath. The tank overflows into the sump through a vertical center stand pipe which is made telescopic, with the upper part commanded by a hand wheel and regulating screw and sliding in a stuffing box, as shown in the detail section. The position of the upper edge of the stand pipe thus determines the level of the water in the bath, and may even be high enough to cause the water to escape first through the fixed overflow. From the lower part of the regulating tank, a suction pipe is run to the pump which supplies the flushing system of the toilet rooms, and the tank does not overflow to waste into the sump until this demand has been satisfied.

All water in excess of this requirement which overflows from the swimming bath reaches the sump and is thence pumped to the sewer by a submerged centrifugal pump driven by a vertical shaft enclosed in a steel tube with the upper bearing above water level. The pump suction has two inlets, one with a strainer to receive water from the sump, and the other connected to the regulating pipe from the bath and to the discharge from the ejectors which deliver the kitchen and cellar drainage to the sewer. All of them are controlled by valves so that the pump can serve either of the three, but it is normally used only for discharging the overflow water which is not required for the flushing system, and that which is delivered to the sump, from the ground water sump at the bath inlet by the steam syphon installed there. When the valve to the regulating tank is closed and that to the pump suction is opened the bath can be emptied by the centrifugal pump in two hours, and the water can be either delivered direct to the sewer or can be circulated through a closed condenser on the exhaust connection of the elevator pumps and thus render additional service before it escapes. Ordinarily the kitchen and cellar wastes and ground water are discharged to the sewer by their own separate automatic apparatus, but connections are made to the centrifugal pump to provide an additional safeguard in case of their disability.

The bath system was designed by Mr. Reginald Pelham Bolton, M. E., consulting engineer for the entire mechanical equipment and sanitation of the building, of which Mr. Paul Duboy is the architect. Milton Schnaier & Company are the contractors for the sanitary work and piping, and the construction of the building and the bath has been carried out by the owner and builder, Mr. W. E. D. Stokes.

The Meeting of the American Society of Mechanical Engineers.

The forty-sixth meeting of the American Society of Mechanical Engineers was held in New York, December 2 to 5. Owing to the illness of the president, Mr. Edwin H. Reynolds, the first session on the evening of December 2, in the Society's house, was called to order by Vice-President Arthur M. Waitt. One paper was presented by Prof. Sidney A. Reeve, entitled, "A Rational Solution of the Problem of Weights and Measures," and after the discussion the meeting resolved itself into a smoker. The system the author advocated is one which subdivides by halves, thirds and quarters.

The second session of the meeting was held on Wednesday morning in the Sturtevant House. The first business of the morning was the presentation of the report of the Council. This document announced the appointment of the following committees: To act with delegates from the American Institute of Architects to plan and arrange for tests on Steel I-beams of Large Size, Mr. H. deB. Parsons and Prof. Palmer C. Ricketts. As a Committee on the Standardization of Screw Threads: Mr. Wilfred Lewis, Mr. George R. Stetson, Mr. George M. Bond, Mr. Charles C. Tyler and Mr. John Riddell. As representatives of the Society on the committee to fix the next award of the John Fritz Medal, Prof. Lanza, Prof. John E. Sweet, Mr. Samuel T. Wellman and Mr. Robert W. Hunt. The Council also reported favorably with respect to the New York monthly reunions. Ninety-three additions to membership were announced, comprising 50 members, 10 associates and 33 juniors, not including promotions.

The meeting next considered the report of the committee on the revision of rules, Mr. Chas. W. Hunt, chairman, devoting the rest of the morning to the subject and voting in favor of the resolution offered a year ago by Mr. C. W. Baker. With the exception of the matter of passing that resolution the topic which occupied the entire period of the meeting was the status of the junior membership in the Society, notwithstanding that in addition to an inquiry in this regard, the committee had asked for an expression of the meeting's attitude as to whether life memberships should be increased, and if so, as to whether the fee should be increased or should be dependent on age, and as to the number of votes which should be necessary to defeat a candidate for election to membership, both on the first and second balloting, besides questions relating to the size of the Council, of a quorum and other matters. With regard to junior membership, Mr. Jesse M. Smith had found that out of 531 juniors in good standing, 177 were of 7 to 20½ years' connection with the Society, 10.13 years on the average, and he thought a likely solution of the problem of rectifying that membership status and of increasing the Society's income at the same time could be secured by some regulation of the junior membership dues. The meeting finally narrowed the discussion to three possible recommendations, of which the last was chosen by vote as indicating the choice of the Society. These proposed rules were: 1.—That the dues of junior members should be progressively increased (for example, after two years' affiliation, the dues should be increased $1 per year for five years); 2.—That after arriving at the period when the dues became equal in amount to those of associate members, the junior should then, ipso facto, become an associate member; 3.—That after reaching the age of 31 years, all juniors should cease to be members of the Society, unless they affiliated with the grades in which they were eligible, except those elected juniors prior to this rule. The resolution of Mr. C. W. Baker provides that a proposed amendment to the rules must be submitted to the Council at least ten days before the opening of a meeting; that it may be rejected by that meeting, after discussion, by a majority vote of members present; and, if accepted by that meeting, that it shall be submitted by letter ballot to the entire voting membership and be passed by a majority vote.

At the beginning of the afternoon session on December 3, the result of the election for officers was announced, as given in this issue among the personal notes. It was then voted to refer the matter of the revision of rules back to the committee and that this committee be increased to five members. The final report of the committee on a standard system of steam-engine testing was presented, together with the discussion on the preliminary forms of the report. Some changes have been made, in the withdrawal of some of the matter pertaining to diagram factors and in the provision that tests may be conducted both of the engine alone and of the plant, the latter in order to include the performance of the engine and auxiliaries together.

The second paper of the convention was then presented, "The Metric System," by Mr. F. A. Halsey. It proved such an interesting subject that the rest of this session and all of the evening session was spent in discussing it and the bill before the House of Representatives providing for the adoption of the metric system for the business of all departments of the Government.

Judging from this and the evening session it appeared that the majority of those present were opposed to the adoption of the metric system, although a very large number of arguments were presented to prove that there was much to be said in favor of the system and of the feasibility of its adoption by American manufacturers. It was felt that a supremacy or invasion of American manufactures in foreign lands would lead to an adoption of the American system of measurements. It was shown in a number of cases that where a particular country is prominent in some one branch of industry, the units of that country are always associated with the products of that industry.

The first item of business of the Thursday morning session was the presentation of the report of the committee on metric measurements by Mr. Charles T. Porter. Its tenor was that the Society should determine for itself what system of units it desired and expressed the opinion that by the end of the century the English system would be the universal one. The Council, by motion of Mr. F. J. Miller, was requested to appoint a number of representatives to confer with other engineering and scientific societies to make an investigation of the subject of the metric system. In this connection a resolution, presented by Mr. Henry R. Towne, was adopted to the effect that notwithstanding some statements that have been printed to the contrary the Society has never officially withdrawn its opposition to the metric system.

A paper was then read by Prof. Reeve, entitled: "Entropy Analysis of the Otto Cycle." On account of the comparatively little time remaining, the rest of the papers were read by title, and were in general not discussed very much, due, however, in part to the absence of a number of the members who had evidently expected to participate at the session in which the papers were scheduled. The first of these papers was that of Mr. J. C. Riley describing an apparatus for obtaining a continuous record of the position of an engine governor. This was followed by a paper on flywheel capacity of engine-driven alternators, presented by Mr. W. I. Slichter, and one entitled: "Heat Resistance the Reciprocal of Heat Conductivity," by Mr. William Kent. Mr. Kent advocates the use of reciprocals of the usual values of heat conductivity of substances, analogous to conductivity and resistance in electricity, in order, for example, that the conductivity of a combination may be obtained in the same manner that it is in electrical work. The coefficient of heat resistance he makes equal to unity divided by the number of British thermal units transmitted in one hour, by a slab of one square foot in area and one inch thick per degree Fahrenheit of difference of temperature between the two faces of said slab, both surfaces being exposed to the still air.

The remainder of the papers discussed at this session were as follows: Mr. J. M. Barnay, on a 44-foot pit lathe; Mr. Chas. T. Porter, on finer screw threads; Mr. C. C. Tyler, on the use of a surveying instrument in the machine shop; Mr. Frank Richards, on gift propositions for paying workmen; and Mr. W. Trinks, on the deflections of beams by graphics.

Thursday evening occurred the main social function of the convention at Sherry's. There was a reception by the acting president, and the president-elect, followed by dancing and a supper.

The Friday morning and last session was held in the Society's house. The following papers were there presented, a number of interesting topics were discussed and the president-elect was formally installed into office. Mr. J. T. Wilkin presented a paper on rotary pumps, Mr. H. M. Lane, on a filing system for office use, Mr. A. F. Nagle, on the analysis of the commercial value of water power, per horse-power per annum, Mr. B. Viola, on centrifugal machines, and Prof. A. Kingsbury, on an oil-testing machine and its results.

Messrs. R. H. Soule and G. M. Basford were announced as additional members of the committee on Rules and By-Laws. Before concluding this report mention should be made of the admirable plan of holding the greater number of the sessions at the Sturtevant House where the large number present were easily accommodated.

Trade Publications.

The Jeffrey Mfg. Co., Columbus, O., has published a profusely illustrated catalogue of 372 pages, devoted largely to elevating and conveying machinery. The book will prove a valuable one. It gives photographs from actual installations of labor-saving and power-transmission machinery of this class applied to all sorts of industries. The various types of conveyors and elevators are so numerous that a detailed reference cannot be made to them. Other apparatus, such as crushers and screens, are described. Price lists are scattered throughout and there is an index at the end.

The Watertown, N. Y., Engine Co. has prepared a booklet describing its line of engines, which comprises simple and compound, vertical and horizontal and four-valve and slide-valve machines. The various details of the machines are described by the aid of a large number of clear engravings.

The P. H. & F. M. Roots Co., 109 Liberty St., New York, is distributing a circular relating to its high-duty positive pressure rotary pumps for suction lifts of 20 to 25 feet, and heads to 400 feet. Some of the pumps are designed to handle 50,000 gallons per minute.

The Automatic Electric Co., Chicago, Ill., has published a catalogue devoted to its automatic telephone system, without switchboard operators, which appears to have an indefinite capacity for handling the business of any exchange. Owing to the extended description and numerous illustrations, a very good idea of the system can be obtained.

The Dodge Manufacturing Co., 128 West Third St., Cincinnati, O., has prepared a brochure descriptive of the Dodge American system of rope transmission, illustrated with a number of views of notable installations.

The Pullman Automatic Ventilator Co., 903 Arcade Building, Philadelphia, has published a 32-page pamphlet illustrating the application of its ventilator to all kinds of buildings and street and railway cars. It consists of a hood and a diffusion box placed in the lower sash rail of a window or in a board below the sash, the hood projecting into the open air and provided with a valve to produce alternately the admitting and exhausting of air.

The December issue of "Graphite," a paper printed for free distribution by the Joseph Dixon Crucible Co., Jersey City, N. J., contains leading articles on graphite brushes for commutators, force feed lubrication, experiments in the use of Dixon's graphite in air-brake equipment, by Prof. W. F. M. Goss, and brass melting. All the matter is not prosaic, however, as a poem, claimed to be an unpublished one of Robert Burns, is also given. Another circular from the Dixon Co. gives the different grades of graphite which it manufactures for use in foundries for the facing of molds.

The Herendeen Mfg. Co., Geneva, N. Y., has lately issued a catalogue describing the Furman boilers for steam and hot-water heating, giving particular details of its new sectional boiler. It is made in widths of from 12 to 40 inches, supplying from 2,450 to 5,700 square feet of steam radiation, or from 4,000 to 9,400 square feet of water radiation. The same catalogue illustrates the Furman portable and brick-set water-tube boilers, the tubes of which are vertical and contain internal diaphragms extending nearly to the bottoms of the tubes to provide circulation.

The November issue of "Ryerson's Monthly Journal and Stock List," published by Joseph T. Ryerson & Son, Chicago, takes the form of an anniversary number commemorating the close of their sixtieth year in business. Through six generations the Ryerson family has been associated with the iron and steel industry. Under "Letters from Old-Timers" a number of choice reminiscences have been collected from veterans in the trade. Another publication from the same firm is No. 6 of Ryerson's New Technical Library and deals with pneumatic tools. In addition to purely catalogue matter this book embodies considerable theoretical and practical information of a general character.

An illustrated article entitled "Underground Wire Rope Haulage" has been published by the Broderick & Bascom Rope Co., and is being distributed free of charge from its St. Louis office, 809 North Main St., and from its New York branch, Frank Baldwin, 33 South St. It is printed in pamphlet form on heavy paper, and is an excellent example of artistic typography. Its illustrations are reproductions from photographs of practical applications of the system and its text has the merit of being concise.

The Reliance Machine & Tool Works have recently issued a booklet, No. 2, containing cuts and brief descriptive matter concerning the Hooke steam pumps and air compressors for all kinds of service. Appended to each cut is a table of sizes and capacities that will be appreciated by the engineer.

In Bulletin No. 2 the De Laval Steam Turbine Co., 74 Cortlandt St., New York, describes a new line of direct-connected direct-current turbine-dynamos in sizes of from 1½ to 300 horsepower. It gives a detailed account of the construction of all parts of the dynamo with numerous illustrations and contains the usual price list and tables of dimensions and capacities.

The United States Naval coaling station at Frenchman's Bay, Me., is described in an illustrated brochure issued by the John A. Mead Manufacturing Co., 11 Broadway, New York. The pier is 400 feet long, the approach pier 305 feet long and the building, which holds 10,000 tons, has a length of 380 feet. Considerable machinery was required for unloading, storing and rehandling the coal.

The Mechanical Cashier is a machine which receives money, places it beyond the reach of the operator, records the transaction and the number of the operator who makes it, makes a record of the total of all transactions and makes change. It is described in a beautifully printed publication by the American Mechanical Cashier Co., 40 Wall St., New York.

Two catalogues have been received from the Atlas Car & Mfg. Co., Cleveland, O. No. 1,008, illustrates a line of cars for use in brick yards and cement plants, and No. 1,012 shows its cars for use in rolling mills, foundries, etc. Both catalogues contain information concerning tracks, turntables and other accessories for car conveying.

A flyer is being distributed by the Pittsburg Meter Co., East Pittsburg, Pa., containing some interesting facts about the Frick Building of Pittsburg. For example, it is 21 stories high, measuring 360 feet from basement level to roof and contains 532 offices. Its ten passenger elevators travel 250 miles daily and carry 20,000 people. It is equipped with two 6-inch Keystone water meters with a combined daily capacity of 2,600,000 gallons.

Personal and Obituary Notes.

Mr. P. W. Gates has been elected general superintendent of the Allis-Chalmers Co., with headquarters at Chicago.

Mr. J. Beyers Holbrook has been admitted to the partnership of Charles Henry Davis & Partners, 25 Broad Street, New York, as the firm's heating and ventilating engineer.

John M. Walbrecht, deputy city engineer of Los Angeles, Cal., died at his home in that city on November 26. He was born in Chicago in 1846, and was graduated from the St. Louis School of Engineering.

The Engineers' Society of Western New York, elected the following officers at Buffalo: President, Samuel J. Fields; vice-president, George H. Norton; secretary, L. W. Eighmy; treasurer, George B. Bassett; librarian, William A. Haven; director, S. T. M. B. Kielland.

Mr. Bruce W. Duer has been appointed superintendent of the Pittsburg division of the Baltimore & Ohio Railroad, succeeding Mr. S. P. Hutchinson, who resigned a short time ago to become assistant general superintendent of the Michigan Central Railroad at Detroit.

Mr. Charles A. Van Keuren has been reappointed chief engineer of the Board of Street and Water Commissioners of Jersey City, N. J., for a term of two years. He entered the service of the city, as surveyor, in 1884 and received his first appointment as chief engineer in 1898.

Mr. Charles E. Dafoe has been appointed superintendent of the Northwest division of the Chicago Great Western Railway to succeed Mr. J. A. Kelly, who resigned, and Mr. Charles S. Weston has been appointed superintendent of the Wisconsin, Minnesota & Pacific division, filling the vacancy caused by Mr. Dafoe's transfer.

Prof. C. L. Crandall has been appointed professor in charge of the College of Civil Engineering, Cornell University, for the remainder of the current year, succeeding Prof. Estevan A. Fuertes; and Prof. L. M. Dennis has been made professor in charge of the Department of Chemistry to take the place vacated by the resignation of Prof. Caldwell.

Mr. Desmond FitzGerald, past president Am. Soc. C. E., has resigned his position as engineer of the Sudbury Department of the Metropolitan Water and Sewerage Board of Boston, on account of ill health. He has been in the service of that city since 1873, when he became superintendent of the Western division of the Boston water-works.

George Leach, M. Am. Soc. M. E., died after six weeks' illness at his home in Providence, November 27. He was born in 1843, and began his engineering career working in industrial shops. Since 1891 he has been largely engaged in plant design and erection, for the Brown & Sharpe Manufacturing Co., the Oakdale Manufacturing Co., and others.

Prof. W. Kendrick Hatt, professor of Applied Mechanics at Purdue University, has been granted leave of absence for the remainder of the academic year, and will resume his duties September 1, 1903. During this interval he will be connected with the Road Material Laboratory, Bureau of Chemistry, U. S. Department of Agriculture, Washington, D. C.

Mr. Edward S. Larned has been appointed New England representative of the United Building Material Co., with an office at 101 Milk Street, Boston. For the past six years he has been with the Metropolitan Water Board, lately as principal assistant engineer in direct charge of masonry construction and of the cement testing laboratory of the Weston aqueduct.

Prof. Henry Mitchell died of heart disease in Boston, December 1, aged 72 years. He was a member of the Mississippi River Commission for many years, a member of the American Society of Civil Engineers since 1880 and a member of the National Academy of Arts and Sciences. Without the advantages of a college education, he achieved a position of prominence.

At its meeting in New York this week the American Society of Mechanical Engineers elected the following officers: President, James M. Dodge, Philadelphia; vice-presidents, F. H. Daniels, Worcester; James Christie, Philadelphia; John R. Freeman, Providence; managers, R. C. McKinney, New York; S. S. Webber, Trenton; Newell Sanders, Chattanooga; treasurer, William H. Wiley.

Salem Howe Wales, a prominent figure in both the municipal and business life of New York City, and for nearly 24 years managing editor of "The Scientific American," died at his home in that city December 2, of apoplexy. He was born in Wales, Mass., in 1825, and came to New York in 1846, where two years later he became associated with "The Scientific American." In 1855 he was appointed New York State commissioner at the Paris Exhibition. In 1873 he was made Park Commissioner of New York, and later became president of the commission, and besides a number of years in this service was also for a time president of the Dock Department. He was one of the early commissioners of the New East River Bridge, was one of the founders of the Metropolitan Museum of Art and a director and member of a large number of institutions of business, art, science and charity.

CONTRACTING NEWS

OF SPECIAL INTEREST TO

CONTRACTORS, BUILDERS, ENGINEERS AND MANUFACTURERS

OF ENGINEERING AND BUILDING SUPPLIES.

For Proposals see pages xvii, xix and xx.

WATER.

Norwalk, Conn.—At a recent citizens' meeting a vote was taken in favor of extending the 16-in. water main from its present terminal at Daniels' mill to the distributing reservoir on Spring Hill, a distance of 23,700 ft. Estimated cost, $70,000 to $80,000.

Hartford, Conn.—The Water Bd. has secured the option on considerable property in the meadows north of the New England R. R. for the new system of filtration of Connecticut River water, which the Commissioners have under consideration.

Long Island City, N. Y.—Bids are wanted Dec. 18 for furnishing, delivering and laying water mains in several streets in the Boro. of Queens. Robt. Grier Monroe, Water Comr., N. Y. City.

Erie, Pa.—Geo. C. Gensheimer, Secy. and Treas. of City Water Works Comrs., writes that preliminaries have just been started for the proposed extension of the present intake from the crib in Erie Bay through Presque Isle and into Lake Erie. The engineer's work will probably not be finished before next spring. Estimated cost, about $200,000. Geo. H. Fenkell, Engr. in Charge.

Great Notch, N. J.—Bids are wanted at once by Stewart & Abbot, Ltd., Times Bldg., N. Y. City, for doing about 30,000 cu. yds. of earth stripping at Cedar Grove Reservoir, Great Notch, N. J.

Rochester, N. Y.—Mayor Rodenbeck has disapproved the ordinance providing for the purchase or condemnation of Cobbs Hill as a site for a reservoir.

Buffalo, N. Y.—Comr. of Pub. Wks. Ward recommends the expenditure of $70,000 for 10 new boilers with fittings at the water works plant.

Baltimore, Md.—The Bd. of Awards is reported to have awarded the contract for building a storehouse on Gay St., to be used by the Water Dept., to Jas. W. Arthur, at his bid of $29,952.

Long Branch, N. J.—The Bd. of Comrs. has granted a 10-year contract to the Tintern Manor Water Co. to supply the city with water for municipal and other purposes. Rufus Blodgett is Pres. of the Co.

Ocean City, N. J.—At the annual meeting of the Ocean City Water and Sewer companies held recently it was decided to spend $10,000 in improvements before next season.

Newark, N. Y.—The contract with the Newark Water Works Co. expires in Oct., 1904, and local press reports state that there is a growing sentiment in the village in favor of the purchase of the present plant or the construction of a new plant to be owned by the village.

Coatesville, Pa.—The Boro. Council has under advisement the question of asking the voters to authorize a loan of $50,000 for the purpose of improving the water and sewer systems of the Boro.

Scotia, N. Y.—Local press reports state that the survey has been completed for the village water works to be constructed next summer. The new reservoir is to be located on Horstmann farm, and have a capacity sufficient for a population of 20,000.

Nassau, N. Y.—Local press reports state that R. H. Strong, of Albany, has the contract for constructing a system of water works for $10,500.

Jersey City, N. J.—The Consolidated Water Co., principal office, Corporation Trust Co., 15 Exchange Place, Jersey City, has been incorporated, with a capital of $2,000. Incorporators, John D. Stocker, Wm. Walker and Chas. H. Wellea.

Allegheny, Pa.—The Councils Water Com. has approved ordinances authorizing the City Recorder and the Dir. of Pub. Wks. to ask for bids for a pumping station on B'way, 2 electric pumping engines for the same and 2 iron water tanks to be located on Greentree Hill.

Penngrove, N. J.—The Council has under consideration the proposition of Geo. Pfeiffer, of Camden, to seek artesian water at his own expense if the Council will give him the contract to erect the water plant.

Parkside, Pa.—The Parkside Water Supply Co. has been incorporated with a capital of $5,000.

McKees Rocks, Pa.—Local press reports state that the Pittsburg & Lake Erie R. R. Co. has awarded to the Kennecott Water Softening Co., of Chicago, Ill., the contract for a plant at McKees Rocks, having a capacity of 1,500,000 gal. per day. Cost, $20,000.

Danielsville, Pa.—A charter has been granted to the Lehigh Acme Water Co., of Danielsville. Capital stock, $1,000. Incorporators: F. M. Hower and H. H. Hower, Danielsville; W. E. Beck, of Nazareth, and others.

Atlantic City, N. J.—The Water Comrs. have asked the City Council to issue $150,000 bonds to cover the cost of increasing the capacity of the water plant and making numerous improvements.

Griffin, Ga.—See "Sewerage and Sewage Disposal."

Lexington, Va.—The Town Council is said to be taking steps for the general installation of water meters in the town.

Richmond, Va.—The Common Council on Dec. 1 adopted the recommendation of the Water and Finance Com. in reference to the issue of $405,000 bonds for the erection of settling and coagulating basins and the construction of a stand-pipe in the western part of the city.

Chicago, Ill.—Bids are wanted Dec. 11 for furnishing and delivering the following approximate quantities of cast iron water pipe: 400 pcs. of 4-in., 4,000 pcs. of 6-in., 3,000 pcs. of 8-in., and 500 pcs. of 12-in. internal diameter; also for furnishing and delivering during the term ending Dec. 31, 1903, the following: Special castings for water pipe; cast iron rings and covers for hydrant chambers; necessary patterns and from these patterns to construct and deliver complete cast iron valve basin covers, and for furnishing and delivering at the water works shops, 22d St. and Ashland Ave., all hydrants and stop-valve castings. F. W. Blockl, Comr. of Pub. Wks.

Wellsville, O.—Bids will be received by the Bd. of Water Wks. Trus. until Dec. 16 for 2 triple single-acting pumps of 2,000,000 gals. per 24 hours capacity, 2 gas engines of 175 H.-P. and 1 hand-power traveling crane of 20 tons capacity. For specifications address Robt. W. Hunt & Co., Monongahela Bank Bldg., Pittsburg, Pa. Wm. Perkins, Supt.

Findlay, O.—City Engr. John W. S. Riegle writes that the time for receiving bids, for laying 10.6 miles of 24-in. vitrified pipe or 10.6 miles of 20-in. cast iron pipe, has been postponed to make tests for a water supply at a point nearer to the city.

Minneapolis, Minn.—City Engr. G. W. Sublette writes that the contract for placing steam mains and feed pipes in the new northeast pumping station has been awarded to Robinson & Cary Co., of St. Paul, for $3,298.

Cincinnati, O.—See "Power Plants, Gas and Electricity."

Reinbeck, Ia.—According to press reports, W. P. Walsh, of Grundy Center, Ia., seeks a franchise for an electric light and water plant.

Alexandria, Ind.—Press reports state that the Council proposes to establish the meter system.

Henderson, Minn.—A water works system is said to be under consideration.

Moline, Ill.—The Council is said to be considering the purchase of additional meters.

Buffalo, Minn.—The proposition to install a water and light plant at a cost of $15,000 is being agitated.

Barnesville, O.—John P. Force, of Columbus, is reported to have been engaged by the Council to prepare an estimate of the cost of water works and a sanitary sewerage system. Mr. Force is said to be in favor of a municipal water system, using drilled wells as the source of supply, with a pumping station and a stand-pipe or elevated tank having a capacity of 100,000 gal.

Duluth, Minn.—The Common Council has approved the bid of N. J. Upham & Co. for the purchase of $140,000 bonds; said bonds to be used for the purchase of the West Duluth water plant, to incorporate it in the general municipal plant.

Dubois, Ill.—The Illinois Central R. R. Co. is reported to have purchased a tract of land in Dubois on which to construct a reservoir by building a dam 600 ft. long and 20 ft. wide. W. J. Harahan, Ch. Engr. of R. R., Chicago.

Marinette, Wis.—Local press reports state that the Marinette Water Co. has asked for bids for lowering the intake pipe of said Co., which crosses the Menominee River. Estimated cost about $30,000.

Cincinnati, O.—The Bd. of Water Works Trus. has decided to sell to the sinking fund trustees $75,000 worth of manuscript bonds.

Two Harbors, Minn.—At a recent special election the Council was authorized to issue water and light improvement bonds to the amount of $24,000.

Clinton, Ind.—The Council has been petitioned for a franchise to establish a water system.

Ottumwa, Ia.—City Engr. J. T. Brady writes that bids were received Dec. 1 as follows for furnishing and laying C. I. water pipe, in all 470 net tons of pipe, and 19,000 lbs. of specials: The U. S. Cast Iron Pipe & Fdy. Co., Chicago, for furnishing pipe delivered by Feb. 1, 1903, bid $35.25 per ton for 6-in., $34.25 for 8-in., $33.25 for 12-in., 14-in. and 16-in.; $60 per ton for specials. The Des Moines Bridge & Iron Wks., Des Moines, for laying pipe, work to be finished by April 1, 1903, bid 46 cts., 48 cts., 54 cts., 68 cts. and 65 cts. for 6, 8, 12, 14 and 16-in. pipe and specials per ft.

Clarion, Ia.—The Council is reported to be considering the question of building a water works plant.

Oshkosh, Wis.—The Oshkosh Water Works Co. has filed an amendment to its articles of incorporation, increasing its capital stock from $200,000 to $300,000.

Austin, Minn.—The State Bd. of Investment has authorized a loan of $25,000 to this city for the purchase of a water works plant.

Searcy, Ark.—Bids will be received by Emmet Snipes, Secy. of Comn. until Dec. 26 for constructing a water works and electric light plant. Owen Ford, Consulting Engr., 710 Security Bldg., St. Louis, Mo.

Springfield, Tenn.—See "Power Plants, Gas and Electricity."

Memphis, Tenn.—The Council has adopted the report of the Water Com. recommending that the city purchase the plant of the Artesian Water Co. E. B. LeMaster, Chmn. of Water Com.

Kansas City, Mo.—The Council is reported to have appropriated $4,000 for about 100 additional fire hydrants to be erected in the business part of the city.

Marshall, Tex.—Bonds to the amount of $25,000 are reported to have been sold for the betterment of the water works.

Sheffield, Tex.—The City Council has granted to Parsons Sons & McIntyre a 30-year franchise for a water works.

Cameron, Mo.—The subject of water works is being agitated by the business men of this place.

Vicksburg, Miss.—Gov. Longino has approved an amendment to the charter of Vicksburg which gives this city additional rights to issue $300,000 municipal bonds for the purpose of building water works, sewerage, a city hall, etc.

La Follette, Tenn.—Press reports state that Pennsylvania capitalists propose to spend $250,000 in a water works system for this city.

Kingman, Kan.—Citizens of this place are said to be considering the bonding of the city to the amount of $35,000 for the construction of water works.

Wilbur, Wash.—Bids will be received by the Town Council until Dec. 17 for furnishing material and constructing a water works system and pumping plant, work to include 7,200 ft. of 4 to 8-in. pipe, the construction of a cement and concrete reservoir, a brick pump-house, installation of a gasoline engine and pump. Bids will be received on steel lap welded pipe and wood stave galvanized wound asphalted pipe. Geo. N. Matzger, Town Clk.

Havre, Mont.—The City Council will receive bids until Dec. 20 for the construction of water works, estimated to cost $20,000; also for electric lights.

Denver, Colo.—A. L. Fellows, Hydrographer, U. S. Geological Survey, writes from Denver that the construction of the Gunnison tunnel will depend upon the decision of the Secy. of the Interior. The work as planned provides for 1 tunnel 4 miles long and 1 tunnel of 2 miles, with perhaps 50 miles of canal. Estimated cost, $1,500,000.

Warner, S. D.—A company is being formed to sink an artesian well.

Egan, S. D.—A water works system is said to be projected by the village. Estimated cost, $6,000.

Souris, N. D.—Press reports state that bids are being taken by this village for boring a well. A. C. O. Lomen, Clk.

Wenatchee, Wash.—Local press reports state that this city will probably construct a new system of water works next summer the source of supply to be Wenatchee River.

Santa Barbara, Cal.—Steps have been taken by the city to acquire by condemnation sites for a reservoir and retaining dam in the Mono flats, involving an area of 2,000 acres; the object being to increase the water supply of this city. In order to connect with the lands specified it will be necessary to run a tunnel through the Santa Ynez mountains, a distance of about three miles. Estimated cost, $500,000.

Los Angeles, Cal.—Supt. of Water Works Wm. Mulholland writes that the following bids were opened Nov. 24 for 2 250-H.-P. water-tube boilers for the pumping plant at Buena Vista: John Wigmore & Sons, Los Angeles, Cal., $9,499; Fulton Engine Wks., Los Angeles, $8,342; Baker Iron Wks., Los Angeles, $10,645; Western Electric Co., Los Angeles, $11,100; Stirling Co., Chicago, Ill., $8,525 (awarded). The time for receiving bids for a pump has been deferred; time not yet set.

Suisun City, Cal.—The question of establishing a water plant is said to be under consideration.

Hinsdale, Mont.—Articles of incorporation of the Rock Creek Canal Co. have been filed with Secretary of State. The Co. proposes to build ditches, canals and flumes for purposes of irrigation, and has a capital stock of $9,600. The principal place of business will be at Hinsdale. The incorporators are: Wm. M. Wooldridge, Fred Hellesten, Jerome Hutchens, and others, of Hinsdale.

Los Angeles, Cal.—Imperial Water Co., No. 8, has been incorporated, with a capital of $1,000,000. Directors: F. C. Paulin, W. J. Boden-Hamer, R. T. Perry, J. C. Coy, J. W. Oakley.

Colorado Springs, Colo.—The special water committee appointed to arrange some plan of unwatering the Cripple Creek district is reported to have adopted a plan known as the El Paso tunnel, and estimated to cost between $80,000 and $100,000. Sherwood Aldrich is Chmn. of Com.

The Trus. of the North Side Water Works are reported to have let a contract to the Iron City Mfg. Co. for a standpipe to be erected at Fairmount Park for $6,900, and the contract for 3 miles of pipe, leading to the tower, to the Holme & Allen Pipe Co. for $35,000.

Aguascalientes, Mex.—See "Sewerage and Sewage Disposal."

North Toronto, Ont.—Local press reports state that further extensions of the town's water works system are contemplated.

Hamilton, Ont.—See "Sewerage and Sewage Disposal."

Durango, Mex.—Julian Bermudez, representing Eusebio Rodriguez, Nicolas Lopez and Manuel Soto Martinez, is reported to be soliciting permission to construct an irrigation dam at San Juan del Rio with the object of irrigating the ranches of La Galera and La Boca di Cachila.

SEWERAGE AND SEWAGE DISPOSAL.

Boston, Mass.—Bids will be received by the Metropolitan Water and Sewerage Bd. until Dec. 15 for building Section 48 of the high-level sewer in Quincy. Length, 5,880 ft.; average cut in embankment, 12 ft.; inside diameter of sewer, 135x150 inches. Wm. M. Engr.

Stamford, Conn.—Surveys are being made under the direction of City Engr. Paul Nash for the East Side sewer.

New York, N. Y.—Bids are wanted Dec. 15 for constructing sewers and appurtenances in portions of Vyse St. Louis Haffen, Pres. Bronx Boro.

Washington, D. C.—The time for receiving bids for the construction of a sewerage pumping station has been changed from Dec. 20 to Jan. 3, as advertised in The Engineering Record.

Brooklyn, N. Y.—Bids are wanted Dec. 17 for furnishing material and constructing a 36-in. brick and 12, 15, 18 and 24-in. vitrified stoneware pipe sewers in portions of several streets. J. Edw. Swanstrom, Boro. Pres.

Camden, N. J.—City Engr. Farnham has completed the survey made with a view to ascertaining what changes will be necessary in the sewer system along Bridge Ave., on account of the proposed elevation of the tracks of the Pennsylvania R. R. Co., on said street.

Coatesville, Pa.—See "Water."

Harrisburg, Pa.—Highway Comr. McConkey is reported to have received the following bids for the construction of State St. sewer: J. S. Bayard, $9,950; Bradley & Caldwell, $10,080; Fisher & Lynch, $9,975.

New Brunswick, N. J.—Property owners of Highland Park, at a recent meeting, considered plans for a sewerage system as prepared by Augustus N. Whitlock, and plans for the Raritan Ave. branch of the system, estimated to cost $6,000, were adopted.

Erie, Pa.—The Mayor has approved an ordinance for a sewer in McCarter and Pennsylvania Aves.

Rockaway Beach, L. I., N. Y.—The Property Owners' Association has appointed a committee to call upon Boro. Pres. Cassidy, the Bd. of Health and Mayor Low to urge the necessity of a sewer system at the beach. Surveys and plans prepared a year ago by the Topographical Bureau of the City of New York call for a sewerage system and disposal plant, estimated to cost $350,000.

Brooklyn, N. Y.—The contract for constructing a sewer in 92d St., from 11th Ave. to N. Y. Bay (bids opened Oct. 29), has been awarded to Jas. Malloy & Co., of Bridgeport, Conn., at $656,233.

Griffin, Ga.—An election will soon be held here to vote on the issue of $100,000 bonds for the purpose of putting in a sanitary sewerage system, improving the light and water plants, and for other improvements.

Pensacola, Fla.—Waring, Chapman & Farquhar, 874 Bway., New York City, have just finished surveys and are preparing plans for sewerage, street grading, paving and surface drainage for this city.

Richmond, Va.—Maynard & Ford are reported to have received an $8,000 contract for the construction of a sewer on Broad and 30th Sts.

Miami, Fla.—Local press reports state that the City Fathers are receiving bids for constructing a sewer in a portion of 8th St.

Chillicothe, O.—Bids are wanted Dec. 22 for furnishing material and constructing an 8-in. sewer in a portion of Second St.

Cincinnati, O.—The Bd. of Pub. Service has approved specifications for a sewer in Eastern Ave., to cost $10,618, and for one in Morris Place, to cost $2,010.

Columbus, O.—The contract for constructing the west side main trunk sewer is stated to have been awarded to J. B. Shetts & Co., of Pittsburg, Pa., for $51,840. For bids received for this work, on Oct. 30, see The Engineering Record of Nov. 8.

The Bd. of Pub. Wks. has adopted a resolution declaring the construction of that part of the west side main trunk sewer system which will be west of Central Ave., to be necessary. Estimated cost, $33,255.

Crookston, Minn.—Local papers quote Geo. A Ralph, Engr. of the State Drainage Bd., as having stated that as a result of the decision of the Supreme Court upholding the State drainage law, work will be undertaken in the spring which will call for the expenditure of over $500,000 for drainage ditches.

Charlotte, Mich.—A petition has been circulated in the townships of Brookfield, Eaton, Carmel, Walton and Bellevue, and presented to the County Drain Comr., asking that Battle Creek be dredged from its source at Narrow lake in Brookfield township to the Bellevue dam. The ditch will be about 30 miles in length and will cost about $75,000 to complete.

St. Joseph, Mich.—The City Council has ordered the Bd. of Pub. Wks. to proceed with the work of constructing a sewer 5,086 ft. long on Wisconsin, Michigan, Morton and Harrison Aves. Estimated cost, $5,203.

Chicago, Ill.—Plans for draining the Calumet region have been presented to the Sanitary Trus. by Ch. Engr. Randolph. He suggested that a canal 70 ft. in width be constructed to connect the Calumet River with the main channel of the sanitary canal, thereby reversing the flow of the Calumet River and diverting large quantities of sewage from the lake. He estimates the cost as follows: Excavation, $8,863,820; right of way, $472,534; bridges, $1,943,500; guard locks, $600,000. Total, $11,879,854.

Milwaukee, Wis.—The Council Com. on Finance has recommended the passage of a bond ordinance for $50,000 for the west sewerage district.

Findlay, O.—The construction of pipe sewers, in E. Lincoln, W. Lincoln, W. Front, 3d and other streets is contemplated. John W. S. Riegle, City Engr.

Gibson City, Ill.—This city is said to be planning to put in a sewer system.

Wichita, Kan.—City Clk. J. L. Leland writes that estimates have not yet been made for the proposed storm water sewer system. H. J. Harding, Engr. in Charge.

Osceola, Ark.—County Clk. W. D. Howard writes that the contract for constructing 27½ miles of drainage canal was let Nov. 28 to C. H. Moore, of Memphis, Tenn., at 12.95 cts. per cu. yd.; estimated contents, 550,000 cu. yds.

Big Spring, Tex.—Acting in conjunction with the Comrs.' Court of Howard County, the Texas & Pacific R. R. Co. will construct a drainage canal through Big Springs as a precaution against floods. Estimated cost, $15,000.

Vicksburg, Miss.—See "Water."

Marysville, Cal.—Marsden Manson, of San Francisco, is reported to have completed an inspection of this city and its surroundings in relation to the proposed installation of sewerage and drainage systems. Plans for said improvements will be adopted by the Council and a bond issue of $50,000 submitted to the people.

Oakland, Cal.—Bids will be received by the City Council until Dec. 20 for constructing a concrete and steel sewer across the right of way of the Southern Pacific R. R. Co. R. W. Church, City Clk.

Aguascalientes, Mex.—Texas papers state that plans are being prepared for a sewer system and addition to the water works.

Montreal, Que.—See "Paving and Roadmaking."

Hamilton, Ont.—The City Council is considering the proposition to submit to the people a by-law for the raising of $100,000 to be expended as follows: West-end sewage disposal works, $50,000; water mains, $5,000; Home for Incurables, $7,000; Ferrie St. opening, $12,500; East-end fire station, $5,000. The balance to be expended on macadam roads.

BRIDGES.

Charleroi, Pa.—A charter is stated to have been granted to the Charleroi & Monessen St. R. R. Bridge Co. to construct a bridge across the Monongahela between Charleroi and Monessen; it will be 1,700 ft. in length, and cost about $175,000.

Beaver Falls, Pa.—A press report states that John Warren, of Beaver Falls; W. A. Park, of Freedom; Richard Holt, of Beaver, and others will on Dec. 12 apply for a charter to build a bridge over Beaver River between this place and New Brighton. The plans are already drawn, and it is said the contract for the stone work has been let.

Steelton, Pa.—Dr. W. R. Powell is reported interested in the construction of an iron bridge, about 50 ft. in width, between Steelton and New Cumberland.

Erie, Pa.—An ordinance has been approved authorizing the construction of an overhead crossing over the P. R. R. tracks on Buffalo Road, at an estimated cost of $45,000 (exclusive of damages). The P. R. R. assumes $20,000, the Erie Electric Motor Co., which will have a track crossing the structure, assumes $15,000, and the city assumes the balance. This crossing, which will be a steel structure on masonry abutments with filled approaches and paved top, will eliminate two grade crossings.

Buffalo, N. Y.—Bids will be received by the Dept. of Pub. Wks. until Dec. 9 for constructing retaining walls, wing walls, piers and roadway on Sprenger Ave. at Scajaquada Creek; also for taking down, moving and resetting bridge now at Perry St., over Ohio Basin Slip at Sprenger Ave. and Scajaquada Creek. Bids will also be received until Dec. 12 for constructing substructure for a bridge on South Park Ave. over Cazenovia Creek. Francis G. Ward, Comr.

Seneca Falls, N. Y.—The proposition to borrow $15,000 with which to purchase land and construct the Ramsey St. bridge is reported to have carried at the recent election.

Warsaw, N. Y.—The Wyoming Co. Superv. are reported to have granted the following towns permission to issue bonds to repair bridges destroyed by the July floods. Benningtin, $12,500; Eagle, $3,250; Java, $8,600, and Sheldon, $9,000.

Allegheny, Pa.—Separate bids will be received until Dec. 11 for doing the following work: Constructing and erecting superstructure; constructing piers and abutments; and for paving the roadway and sidewalks of a bridge across Woods Run Valley in Shady Ave. D. L. Fulton, Dir. Dept. of Pub. Wks.

Tonawanda, N. Y.—A correspondent writes that the Town Bd. has awarded the contract for constructing the superstructure and steel work for a bridge across Two Mile Creek, to the Rochester Bridge & Construction Co. for $9,350.

New York, N. Y.—Mayor Low has approved the bond issue of $350,000 for the construction of a bridge across East Chester Bay, in Pelham Bay Park, Bronx Boro.

McKees Rocks, Pa.—Local press reports state that the business men of this city have taken up the matter of building a bridge across Chartiers Creek at Furnace St., to connect with Sheridan.

Doylestown, Pa.—The Jury appointed to view the site for a bridge across Park Creek, on the Kansas Road, reports in favor of constructing a structure, to cost not more than $9,000.

Wrightsville, Pa.—It is stated that the Pennsylvania R. R. Co. intends constructing an elevated span over the top of the bridge connecting Wrightsville and Columbia, to be used by vehicles and pedestrians.

Scranton, Pa.—It is reported that bids will soon be asked by Dir. of Pub. Wks. Roche for constructing the W. Lackawanna Ave. viaduct.

Columbia, S. C.—See "Electric Railways."

Hammond, Ind.—The Michigan Central Ry. Co. is reported to be preparing to place a new bridge over Calumet River, west of this city. The structure will be a 500-ton draw bridge. W. S. Kinnear, Ch. Engr., Detroit, Mich.

Kokomo, Ind.—The Co. Comrs. are reported to be figuring on 2 new bridges, one over Charley Creek, to be built as soon as the City Council and Co. Comrs. agree as to the kind of structure needed, and the other over Wabash River, to cost about $30,000.

Racine, Wis.—Engineers are reported to be in the city looking over the ground and laying out stakes for the proposed new bridges for the Northwestern Ry. Co. The 6th St. viaduct will be made into a double structure and a new double swinging bridge will be constructed over the river. Edw. C. Carter, Ch. Engr., Chicago, Ill.

Boscobel, Wis.—It is reported that the wooden bridge over Sanders Creek, at Oak and Bell Sts. in the 1st Ward, has been condemned, and the city will at once commence the erection of an iron structure.

Montezuma, Ia.—Press reports state that bids will be received by the Co. Aud. until Jan. 5 for constructing county bridges during the year 1903.

Dayton, O.—The officials of the Cincinnati, Hamilton & Dayton R. R. are reported to have submitted to the Bd. of City Affairs, plans for the construction of overhead bridges for pedestrians at Albany St., Edgemont and Kiefer Sts., North Dayton.

Portland, Ind.—Bids will be received by the Co. Aud. until Dec. 18 for constructing an iron bridge across Salamonia River in Green Township, to be 120 ft. long, 16-ft. roadway and 16-ft. truss.

Columbia City, Ind.—Bids will be received by the Bd. of Co. Comrs. until Dec. 19 for constructing several small steel truss bridges, ranging in size from 14 to 56 ft. long. W. H. Carter, Co. Aud.

Decatur, Ill.—The cost of the proposed viaduct at the West Main St. crossing of the Wabash Ry. has been estimated at $45,000.

Chicago, Ill.—Local press reports state that Lydon & Drews Co. have secured the contract for the substructure of both Loomis St. and 18th St. bridges at $62,728 and $63,854, respectively. The contract for the superstructures is reported to have been secured by Jackson & Corbett Co., at $121,620 for Loomis St., and $115,870 for 18th St.

Saginaw, Mich.—Local press reports state that the American Bridge Co., Lafayette, Ind., submitted the lowest bid Nov. 26 for constructing a 2-span bridge across Cass River, at $8,990 for the 120-ft. span, and $10,400 for the 150-ft. span; total, $19,800. The cost had been estimated at $15,000 and it is reported that these bids will likely be rejected and new bids asked.

Hot Springs, Ark.—Deputy Circuit Clerk J. M. Anderson, ex-Mayor W. W. Waters and Jas. Richards are stated to have been appointed as a commission by County Judge O. H. Sumpter to build a steel bridge across Ouachita River, on Central Ave., to cost about $80,000.

Phoenix, Ariz.—It is stated that a bridge will be built over Salt River by the Phoenix & Eastern R. R. Co. F. M. Murphy, Pres., Prescott.

Stockton, Cal.—Carl Salbach, Deputy Co. Clk., writes that it is proposed to construct a bridge at Millers Ferry, between San Joaquin and Sacramento Counties. For further information address F. E. Quail, Co. Surveyor, Stockton.

Spokane, Wash.—Local press reports state that the City Engr. has been instructed to prepare plans for a steel and wood high bridge to be built across Hangman Creek.

San Bernardino, Cal.—Superv. Glover has received permission from the Bd. of Superv. to purchase 2 80-ft. steel spans for a bridge to cross Warm Creek at East Colton Ave.

Redding, Cal.—The Co. Surv. has been directed to prepare plans and specifications for a steel bridge, of the Platt truss pattern, to cross Pit River at Elena, also for a steel bridge, of the same kind, to cross Pit River near Baird. It is reported that the plans are to be presented at the January meeting of the Bd. of Superv. when bids for construction will be called for.

New Westminster, B. C.—City Clk. W. A. Duncan writes that contracts have been let as follows for the construction of an $800,000 bridge across Fraser River at New Westminster: Substructure, to Armstrong, Morrison & Balfour; superstructure, to Dominion Bridge Co.

Joliette, Que.—See "Railroads."

PAVING AND ROADMAKING.

Boston, Mass.—The Street Comrs. have reported the estimated cost of widening Albany St., from Troy to Lehigh Sts., at $90,000, of which $75,000 is for land and building damages and $15,000 is for construction.

Quincy, Mass.—The City Council has authorized Mayor Bryant to petition the Legislature to appropriate $200,000 for building a State boulevard along the shores of Quincy Bay to the Blue Hills.

Pittsfield, Mass.—City Clk. Jos. Ward Lewis writes that on Dec. 2 it was voted to issue $100,000 bonds for street paving.

New York, N. Y.—Bids are wanted Dec. 12 for furnishing material and paving with asphalt the new-made land between 18th and 21st Sts., East River, and with granite between piers old 20 and new 16, East River. McDougall Hawkes, Comr. of Docks, Dept. of Docks and Ferries.

Butler, Pa.—This Boro. will issue $30,000 bonds for street improvements.

Allegheny, Pa.—See "Bridges."

Salisbury, Md.—Property owners are said to be interested in a movement to pave the business streets of this city.

Jersey City, N. J.—The Street and Water Bd. has adopted a resolution declaring that the only pavements which should be put down in this city, in the future, are Belgian, granite and asphalt.

New York, N. Y.—Bids are wanted Dec. 15 for regulating and laying macadam pavement on a telford foundation on a portion of Arthur Ave., Engrs.' estimate, 22,700 sq. yds. pavement, 8,700 lin. ft. of curbstone rejoined and reset; for regulating and grading, setting curbstones, flagging sidewalks, laying macadam pavement on a portion of Morris Ave., estimated quantities, 3,400 sq. yds. of macadam, 7,780 sq. ft. new flagging, 1,010 sq. ft. new bridgestone for crosswalks, etc.; for regulating, grading, setting curbstones, flagging sidewalks, etc., on portions of several streets requiring in all 101,210 sq. ft. of new flagging; for paving with granite block the roadway of E. 133d St., requiring 7,060 sq. yds. of granite block pavement laid on a sand foundation with sand joints, and for repaving with asphalt pavement on the present block pavement the roadway of 144th St., requiring 5,050 sq. yds. of asphalt pavement, including binder course, and 5,050 sq. yds. of old stone pavement, to be relaid as foundation or in approaches, etc. Louis F. Haffen, Pres. Bronx Boro.

Schenectady, N. Y.—Bids are wanted Dec. 9 for furnishing material and grading, curbing and paving portions of Lincoln Ave. and Seward Place. Address City Engineer.

Williamstown, N. J.—It is stated that bids will be received by the Monroe Township Com., H. B. Garwood, Chmn., until Dec. 20, for constructing about 9,350 ft. of Main St. Wm. C. Cottell, Township Engr., Wenonah, N. J.

Reading, Pa.—An ordinance is pending in the Council providing for an increase in the appropriation for paving Cherry St., to a total of $15,000; work to be done in the spring.

Erie, Pa.—The Mayor has approved an ordinance for curbing and paving German St., from 8th to 18th Sts.

McKeesport, Pa.—It is stated that bids are wanted Dec. 18 for grading, curbing and paving on portions of Fourth Ave. and Diamond St. R. A. Hitchins, City Compt.

Niagara Falls, N. Y.—The Common Council has rescinded all previous action in regard to the paving of Niagara Ave., and has adopted a new resolution declaring its intention to pave the avenue with waterproof bituminous macadam at a cost not to exceed $69,561.

Cumberland, Md.—The Council has authorized the paving with vitrified brick of Green St., at a cost of about $12,000.

Pensacola, Fla.—See "Sewerage and Sewage Disposal."

St. Augustine, Fla.—It is stated that bids are wanted Dec. 30 for paving with vitrified brick the north end of Washington St. John M. G. Carrera, City Clk.

Cincinnati, O.—Bids will be received by the Bd. of Pub. Service until Dec. 22 for furnishing material and improving a portion of Gilbert St. by paving and repaving the roadway with granite blocks redressing and resetting old curbs, furnishing and setting new granite curbs where necessary and relaying old and furnishing and laying new granite crossings. Bids will also be received at the same time for improving a portion of Rochelle St., by grading, setting curbs, and paving the roadway with brick and constructing the necessary drains. Geo. F. Holmes, Clk.

Chicago, Ill.—Bids will be received until Dec. 10 by the Lincoln Park Comrs. for furnishing 10,000 to 20,000 sq. yds. of blocks for paved beach work on the lake front near North Ave. Bids must be made for blocks delivered at work and also F. O. B. Chicago; delivery to begin not later than April 1, 1903. Sizes of block to be 4 to 5½ in. wide, 6, 7 and 8 in. deep and 9, 12 and 14 in. long. W. W. Tracy, Pres.

Glenville, O.—Bids are wanted Dec. 13 for grading, curbing, flagging and improving a portion of Lakeview Ave. B. F. Davis, Jr., Village Clk.

Keokuk, Ia.—City Engr. J. Ross Robertson writes that the following bids were opened Nov. 29 for brick paving to be done in the spring of 1903: *a*, 4,574 yds. of brick paving; *b*, 1,860 ft. curb; *c*, 1,344 yds. of excavation: Cameron & McManus, *a*, $1.51½; *b*, 62c.; *c*, 50c. Keokuk Const. Co., *a*, $1.33; *b*, 57c.; *c*, 39c. The contract will be awarded to the Keokuk Const. Co. Work is to be completed by June 1, 1903.

Lake Geneva, Wis.—The Geneva Lake Good Roads Asso. has been formed for the purpose of improving the parks and drives in the vicinity of Lake Geneva, Walworth Co. Incorporators: E. Davidson, Geo. W. Barr, C. S. Douglass, and others.

La Crosse, Wis.—The Common Council has passed ordinances providing for the paving of portions of 3d, Main, Jay and 5th Sts. with brick; also for curbing and macadamizing portions of numerous other streets.

Medford, Wis.—Taylor County Bd. has voted to construct a road 16 miles long from Medford to Aurora.

Holland, Mich.—The Common Council is considering the question of issuing $30,000 bonds for street paving purposes.

Marshalltown, Ia.—The City Council has ordered brick paving on 4th St. and on the east side of the square.

Indianapolis, Ind.—The City Park Bd. has instructed Park Supt. Power to make plans for the condemnation of land, for the Fall Creek Boulevard, under the Park Bd. law. It is hoped to build the driveway next year.

Wichita, Kan.—Bids will be received by the City Clk. for repairing approximately 70,000 sq. yds. of old asphalt pavement for a term of from 1 to 5 years; surface to be 2½ in. thick. Bids to state price per sq. yd. and whether sheet or rock asphalt. A 10-year guarantee is required.

Louisville, Ky.—Local press reports state that bids will be opened by the Bd. of Pub. Wks. Dec. 10 for paving with vitrified brick on a portion of Peterson Ave., cost about $5,000.

Albany, Ore.—It is stated that bids are wanted Dec. 9 for paving a portion of First St. J. S. Van Winkle, Recorder.

Portland, Ore.—Samuel Connell, Pres. of the Albina Improvement Asso., writes that it is proposed to pave the streets of Lower Albina with macadam or crushed stone.

Los Angeles, Cal.—Press reports state that ordinances for 8 miles of street improvements are now pending. Notices will be posted on 18 different streets, covering 39,642 ft. of street improvement.

Denver, Colo.—The Bd. of Pub. Wks. has acted favorably upon the petition to pave 6 blocks of Ogden St. with macadam.

Hamilton, Ont.—See "Sewerage and Sewage Disposal."

Montreal, Que.—In a report to the City Council City Engr. Barlow estimates the total cost of work required to be done by the Road Dept. in 1903 as $2,376,788. Of this amount $293,734 is asked for macadamizing old roads, $128,161 for macadamizing new roads, $197,000 for repairing permanent pavements, $199,042 for wooden sidewalks, $216,272 for paving between car tracks, $504,372 for new pavements, $325,000 for sewers and pump stations, $60,000 for snow removal and a number of smaller items.

POWER PLANTS, GAS AND ELECTRICITY.

Boston, Mass.—See "Public Buildings."

Kenmore, N. Y.—The Bd. of Village Trus. has awarded the contract for laying and installing a gas system to John B. Winter, 94 Amherst St., Buffalo, N. Y., who is lowest bidder at a price of 16c. per ft. for 4-in. pipe, $2.50 for setting lamp posts and $1 for setting syphons. Mr. Winter expects to begin work immediately and complete his contract by Dec. 20th, 1902.

Dansville, N. Y.—It is stated that plans are being prepared, and contracts will soon be let by the Mill Creek Electric Light & Power Co., for its proposed plant.

Cape May, N. J.—Saml. Shields and Chas. Fitzgerald, representing a syndicate, are stated to have purchased the local electric light plant for $95,000.

Philadelphia, Pa.—One bid for supplying naphtha lamps to the city was opened by Dir. of Pub. Wks. Haddock Nov. 26 and it was from the Pennsylvania Globe Gas Light Co., who at present have the contract. The prices offered are $29.50 a year for each Welsbach burner and $21 a year each for the old style Maloney burners. There are 12,537 naphtha lamps. The appropriation to maintain these lamps for the present year was $306,500. The Bureau of Lighting has asked $310,066 for next year.

York, Pa.—The Merchants' Electric Co. is reported incorporated with a capital of $300,000. Chas. H. Bear, Geo. W. Campbell and J. A. Walker, all of York, are among the directors.

Pittsburg, Pa.—The stockholders of the Manufacturers Light & Heat Co., at a special meeting, Nov. 25, voted to increase the authorized capital stock from $5,000,000 to $10,000,000. This means according to reports a vast extension of the company's operations and the taking over of contemporary interests. The Shadyside Electric Light Co. has been incorporated with a capital of $15,000, by John Eaton, W. L. Abbott and others, of the 20th Ward.

Lancaster, Pa.—The stockholders of the Lancaster Gas, Light & Fuel Co. have decided to recommend to the Bd. of Dirs. the betterment of the services, purchase of new equipment, etc.

Aberdeen, Md.—The Aberdeen Electric Light, Heat & Power Co. is reported organized, with D. B. Arthur, Pres., and Dorsey Rowe, Secy. The Town Comrs. are stated to have made a contract with a newly formed company to light the streets for the next 5 years.

Kenmore, N. Y.—Bids are wanted Dec. 15 for the purchase of $5,000 lighting bonds. Chas. V. Busch, Village Treas.

La Salle, N. Y.—The Village Bd. is stated to have granted the Ontario Power & Transmission Co. a franchise for the distribution of power. The company agrees to have 5,000 H.-P. ready for transmission by Sept. 1, and to erect a transformer house in the village.

Y.—The following bids were opened Dec. 1 by the Dept. of Educ., New York City, for alterations in, and additions to, the heating and ventilating apparatus for school 16, Boro. of Richmond: The Baldwin Engineering Co., 107 W. 17th St., N. Y. City, $7,900; Frank Dobson, $9,990; E. Rutzler, $8,775; Williams & Gerstle, $9,368; John Neal's Sons, $8,866; United Htg. Co., $8,840.

Braddock, Pa.—Bids will be received by the Bd. of Educ. until Dec. 15 for erecting a school in Braddock. Plans and specifications may be seen at the office of E. J. Carlisle & Co., Archts., 901 Westinghouse Bldg., Pittsburg. Address, V. C. Knoor, Secy., c. o. E. J. Carlisle & Co., Pittsburg.

Meadville, Pa.—The Trus. of the Meadville Theological School are stated to have decided to erect a $26,000 building.

New York, N. Y.—Bids are wanted Dec. 15 for erecting School No. 183, Boro. of Manhattan, and for installing electric elevators in the Morris High School, Boro. of Bronx. C. B. J. Snyder, Supt. of School Bldgs.

Sterrett, Pa.—Separate bids will be received until Dec. 20 by W. J. Fleming, Secy. School Bd., care of Ellsworth Dean, Archt., 612 Fitzsimons Bldg., Pittsburg, for erecting 2 schools, 1 on Braddock Ave., the other on Linden Ave., 22d Ward, Sterrett.

Spartanburg, S. C.—It is stated that bids will be received until Dec. 15 for erecting a brick and stone Science Hall for the Wofford College at Spartanburg. Avery Carter, Archt., Cleveland Bldg.

Cincinnati, O.—Bids will be received until Dec. 15 by the Bd. of Directors of the University of Cincinnati for erecting a building for observatory purposes on the grounds of the University in Burnet Woods Park. Oscar W. Kuhn, Chmn.

Cleveland, O.—School bonds amounting to $600,000 have been sold.

Jackson, Mich.—Harry J. Rill, 54 Buhl Blk., Detroit, is reported to be preparing plans for an $18,000 school for the Polish Society. Rev. Joseph Heir, Pastor.

Chicago, Ill.—Bids will be received by the Bd. of Educ. until Dec. 12 for erecting a school at Washtenaw Ave. and 15th St., work to include heating, ventilating, plumbing, etc. Address Com. on Bldgs. and Grounds.
The City Council has granted the Bd. of Educ. permission to expend $140,000 for the erection of an English High and Manual Training School at Sedgwick and Division Sts.

Sac City, Ia.—The citizens are stated to have voted to issue $20,000 bonds for a new school.

Leavenworth, Kan.—Wm. P. Feth, of Leavenworth, is preparing plans for the proposed $60,000 high school.

St. Louis, Mo.—Hiram Lloyd, 816 Olive St., is stated to have secured the contract for erecting the Jas. E. Yeatman High School, for $307,766.

Dallas, Tex.—The Dirs. of the Patton Seminary are stated to have decided to erect a hall, with a seating capacity of 1,000.

Lawton, Okla. Ter.—The Bd. of School Directors is stated to have voted to erect 2 schools, one a high school, to cost $25,000, the other to cost $15,000.

Aberdeen, S. D.—The Bd. of Educ. is reported to be considering the erection of a school, to cost about $25,000.

Denver, Colo.—E. P. Varian, 413 Taber Blk., has prepared plans for a $10,000 brick and stone school to be built for the State Home at S. Iliff and Clarkson Sts.

STREET CLEANING AND GARBAGE DISPOSAL.

New York, N. Y.—Mayor Low has approved an ordinance authorizing the issue of $141,144 bonds for new stocks and plant for the Street Cleaning Dept., Boro. of Brooklyn, and $165,557 bonds for stock and plant for the Boroughs of Manhattan and Bronx.

Philadelphia, Pa.—The following bids were opened Dec. 1 by Dir. of Pub. Wks. Wm. C. Haddock, for cleaning the streets, private alleys and public market houses, also for the removal of ashes for the entire city, for the year 1903: Jas. Curran, $714,000; Harmer & Quinn, $691,000; David Peoples, $690,000; Ruch & Bates, $680,000.
Bids were opened at the same time for above work by districts. The lowest bids received were as follows: Districts 1 and 2, from Ruch & Bates, at $115,000 and $168,000 respectively; Districts 3, 4 and 5 from Thos. Parker at $56,000, $159,000 and $119,000 respectively; District 6, from Richard P. Bennis at $23,400. Total by districts, $640,400.

Rochester, N. Y.—Local press reports state that the Bd. of Contract & Supply will soon ask bids for the disposal of garbage.

Chicago, Ill.—The Council has ordered the sum of $14,000 spent for a garbage crematory at the bridewell.

Ft. Brady, Mich.—See "Government Work."

Parkersburg, W. Va.—City Clk. Jesse L. Cramer writes that contracts for the removal of all kitchen garbage and offal accumulating in this city for 1 year from Jan. 1, 1903, have been awarded as follows: 1st and 5th Wards to John W. Curry at $798 and $500 respectively; 2d and 4th Wards to R. A. Little at $639 and $490 respectively; 3d Ward to Richard Ellis at $783.

Des Moines, Ia.—In a proposition submitted by the American Underwriting Co. (represented in Des Moines by A. N. Talcott) to Secy. Milo Ward of the Commercial Exchange, in reference to the disposition of waste of this city, said Co. offers to collect all garbage and all other waste matter, excepting night soil, at $1.40 per ton, and to collect and dispose of night soil in a sanitary and odorless manner at $1.75 per cu. yd. A franchise for not less than 10 years is asked by above Co.

Elwood, Ind.—Local press reports state that estimates are being prepared by S. H. Digel, under instructions from Mayor Smith, of the probable cost of a new garbage furnace.

Monroe, La.—A Com. of the City Council has under consideration the question of the disposal of city garbage.

Oakland, Cal.—The City Council has passed an ordinance granting a franchise to the Pacific Odorless Incinerating Co. to erect a Dixon steel shell crematory; the ordinance provides that after 20 years the crematory shall become the property of the city.

GOVERNMENT WORK.

Ft. McKinley, Me.—Bids are wanted Dec. 27 for constructing a sewer system, with all manholes, outlets, flushing tanks, etc., at Ft. McKinley, Gt. Diamond Island, Me. Address, Capt. A. W. Yates, Q. M., Portland, Me.

Ft. Banks, Winthrop, Mass.—Bids are wanted Dec. 29 for constructing granolithic walks and macadam roads at this post. Address, Lieut. H. B. Grant, Q. M.

Ft. Williams, Me.—Bids are wanted Dec. 26 for constructing, plumbing and electric wiring hospital stewards' quarters. Address, Leroy T. Hillman, Q. M., Ft. Williams, Me.

Portsmouth, N. H.—The Bureau of Yards and Docks, Navy Dept., Washington, has awarded the contract for constructing building No. 60, at the Portsmouth Navy Yard, to Snare & Triest, 39 Cortlandt St., New York City, for $67,750.

Boston, Mass.—Bids are wanted Jan. 2 for constructing at Ft. Strong, Boston Harbor, Mass., an Administration Bldg., a Double Set, N. C. O. Quarters and an Ordnance Storehouse. Address, A. M. Palmer, Depot Q. M., Boston.
Bids are wanted Jan. 5 for dredging in Cohasset Harbor and Weymouth and Town Rivers, Mass. Lieut.-Col. W. S. Stanton, Corps Engrs., U. S. A.

New Castle, Pa.—A correspondent writes that the location of the new government building at New Castle has been decided upon, and contracts will be let for a building to cost about $100,000.

Washington, D. C.—Bids will be received by Jas. Wilson, Secy. Dept. of Agriculture, Washington, until Dec. 17 for erecting a 3-story stone building for the use of the Weather Bureau, U. S. Dept. of Agriculture, on the summit of Blue Ridge Mountains, about 1½ miles from Trappe, Loudoun Co., Va., and 60 miles from Washington, D. C.

Philadelphia, Pa.—The following bids were opened Nov. 29 at the Bureau of Yards and Docks, Navy Dept., Washington, D. C., for the removal of 500,000 cu. yds. of material from the waters of the Navy Yard, League Island, Pa.: American Dredging Co., Philadelphia, 37c. and 40c. per cu. yd.; Bowers Hydraulic Dredging Co., Kansas City, 35c. and 37c. per yd.; H. Steers, Jr., New York City, 25¾c. and 27¾c. per yd.

Philadelphia, Pa.—Bids will be received until Jan. 3 by Mordecai T. Endicott, Ch. Bureau of Yards & Docks, Navy Dept., Washington, D. C., for constructing a retaining wall at the Navy Yard, League Island, Pa. Appropriation available, $85,000.

Washington, D. C.—Bids will be received by the Bureau of Supplies & Accounts, Navy Dept., Washington, until Dec. 16, for furnishing a quantity of steel, steel castings and forgings, structural steel, pipe, pipe fittings, asbestos covering, etc. A. S. Kenny, Paymaster Gen., U. S. N.

Ft. Barrancas, Fla.—Bids are wanted Dec. 23 for constructing a wharf at Ft. Pickins, Fla. Address W. E. Cole, Q. M.

Norfolk, Va.—Bids will be received until Dec. 15 by Jas. Knox Taylor, Superv. Archt., Treas. Dept., Washington, D. C., for installing an electric passenger elevator in the U. S. Court House and Post Office Bldg., at Norfolk.

Ft. Brady, Mich.—Bids are wanted Dec. 24 for constructing a garbage crematory and shed for same at this post. Address Col. E. B. Atwood, Ch. Q. M., Chicago, Ill.

Mobile, Ala.—Bids are wanted at the U. S. Engineer Office until Dec. 29 for dredging in Pascagoula River and Mississippi Sound, as advertised in The Engineering Record.
Bids are wanted Jan. 8 for furnishing, delivering and completing the metal work for Sabine Bank Light Station, Tex. Bids will also be received at the same time for furnishing, delivering and constructing the Sabine Bank Light Station, Tex. Lieut. Col. A. N. Damrell, Corps Engrs., U. S. A.

St. Louis, Mo.—Bids are wanted Jan. 6 for installing in complete working order an ash elevator in the U. S. Custom House and Post Office Bldg., St. Louis. Address, Custodian, U. S. Custom House and Post Office, St. Louis.

Louisville, Ky.—Local press reports state that contracts will be let, so that construction can begin by Jan. 1 for lock No. 6 on Green River. Amount available, $180,000. Maj. Geo. McC. Derby, Corps of Engrs., U. S. A., Engr. in Charge.

New Orleans, La.—Bids will be received until Dec. 28 at the Bureau of Supplies and Accounts, Navy Dept., Washington, D. C., for furnishing at the Naval Station, New Orleans, a power plant. A. S. Kenny, Paymaster Gen., U. S. Navy.

Emporia, Kan.—The following bids were opened Dec. 3 at the Treasury Dept., Washington, D. C., for the construction including plumbing, heating and ventilating apparatus, electric wiring and conduits for the U. S. Post Office at Emporia: Latimer & Benning, Kansas City, Mo., $34,407; J. S. Morse, Topeka, Kan., $34,973; J. W. Berry, Jewell City, Kan., $37,277; Congress Const. Co., Chicago, Ill., $39,923.

Carson, Nev.—Bids are wanted Dec. 20 for furnishing material and constructing a bathhouse and furnishings, at the U. S. Indian School, Carson. For further information apply to Jas. K. Allen, Supt.

Helena, Mont.—Bids are wanted at the Treasury Dept., Washington, D. C., until Jan. 14 for the installation of a conduit and electric wiring system for the U. S. Public Building at Helena, as advertised in The Engineering Record.
Bids are wanted Jan. 3 for installing an electric passenger elevator in the U. S. Public Bldg., at Helena. Jas. Knox Taylor, Superv. Archt., Treas. Dept., Washington, D. C.

Los Angeles, Cal.—The following bids are reported to have been received Nov. 26 by Capt. Edgar Jadwin, Corps of Engrs., U. S. A., for completing the jetty work at San Diego Harbor: P. A. Howard and F. D. Lanterman of Los Angeles, at $2.17 per net ton (awarded); W. H. Healy of San Francisco, $2.39½; Atlantic, Gulf and Pacific Dredging Co., $2.50; Rudolph Axman, $2.47 and Waldo S. Waterman, San Diego, $2.30.

Norfolk, Neb.—Bids will be received until Jan. 15 by Jas. Knox Taylor, Superv. Archt., Treas. Dept., Washington, D. C., for the construction (except heating apparatus, electric wiring and conduits) of the U. S. Post Office at Norfolk.

MISCELLANEOUS.

North Adams, Mass.—The City Council has voted to buy the syndicate property on North Church St. for park purposes, the price to be $24,000.

New York, N. Y.—Bids are wanted Dec. 15 for furnishing labor and material required for constructing and delivering fire pumps for a new fire boat. Thos. Sturgis, Fire Comr.
Bids will be received by the Park Bd. until Dec. 11 for regulating and grading Dewitt Clinton Park. Wm. R. Willcox, Comr. of Parks.

Asbury Park, N. J.—See "Sewerage and Sewage Disposal."

Norfolk, Va.—The Norfolk, Hampton Roads Shipbuilding and Dry Dock Co. (John T. Gamble, of Columbus, O., Secy.) proposes to build a solid concrete or stone 1,000 ft. dry dock.

Richmond, Va.—The Common Council on Dec. 1 passed an ordinance from the Finance Com. recommending that $38,000 be appropriated for the purchase of a new dredge and scows for the improvement of the James River harbor.

Terre Haute, Ind.—Bids are wanted Dec. 10 for 1 100 bbl. steel compression tank; 1 100 bbl. galvanized iron storage tank, for the Bigo Co. Home for Dependent Children. Jas. Soules, Co. Aud.

Ashland, Wis.—A correspondent writes that on Nov. 22 the iron ore dock of the Wisconsin Central Ry. Co. (C. N. Kalk, Ch. Engr., Milwaukee), was burned. Insurance, $173,000.

Indianapolis, Ind.—The Niel Improvement Co. has been incorporated, its purpose being to erect dykes, dams and the like along the banks of Eel River and its tributaries in Clay Co. The incorporators are Henry W. Smith, Harry H. Hyatt, G. M. Williamson, and others.

South Bend, Ind.—The contract for constructing the Austin Heston ditch 12 miles in length, in Union township, has been awarded by the County Surveyor, South Bend, to John Hughes, of Napanee, Ind., at 5.94 cts. per cu. yd., or a total of about $10,000.

Houston, Tex.—The Brazos River Improvement Asso. will, it is stated, request the incoming Legislature for the appointment of a board of engineers to determine on a plan which will be feasible and economical for preventing the overflows which periodically destroy property along the river and its tributaries; also a request will be made to submit to the people a constitutional amendment permitting land owners of the counties along the Brazos and its chief tributaries to form themselves into taxing districts for the purpose of raising money to carry out the plan proposed and adopted by the engineers aforesaid. Estimated cost of work is placed at $5,000,000.

Abbeville, La.—The Inland Canal Co. has been incorporated, and obtained from the police jury of this parish a franchise for 99 years to dig and maintain a system of canals and waterways connecting Bayou Vermillion with Mermentau River by way of Schooner, White Lake and Grand Lake.

NEW INDUSTRIAL PLANTS.

Sellers & Montgomery, Marshalltown, Ia., are erecting a threshing machine factory. The main building will be 2 stories, 40x80 ft., and a 25-H.-P. engine will be installed.

The Goshen, Ind., Novelty & Brush Co. have awarded the contract for a 48x100-ft. factory building and a 20x30-ft. engine room.

The A. A. Cooper Wagon & Buggy Co., Dubuque, Ia., will erect a branch factory in St. Louis.

The Sherwin-Williams Co., Cleveland, O., paint and varnish makers, will build a new plant in Montreal.

A. M. Woolson, Toledo, O., is erecting a 3-story and basement, 40x98-ft., manufacturing building to be occupied by the Toledo National Bread Co., who will install a 25-H.-P. electric motor. The building will be provided with freight elevator, steam heating apparatus, electric wiring, etc. Bacon & Huber, archts.

The Rockland-Rockport Lime Co., Rockland, Me., expects to rebuild its recently burned plant, consisting of a 2-story, 40x90-ft. saw mill, 2-story, 40x100-ft. cooperage and a 30x40-ft. pencil plant, on an enlarged scale and make a number of improvements in the machinery. A 100 to 125-H.-P. engine will be required.

The Norfolk-Hampton Roads Shipbuilding & Dry Dock Co., Norfolk, Va., has been reorganized with the following directors: Wm. P. Harrison, Cincinnati, O., Pres.; Wm. H. Knauss, Columbus, O., Vice-Pres. and Treas.; John T. Gamble, Columbus, O., Secy.; T. J. Davis, Cincinnati, and J. V. Ewan, Covington, Ky. The company has bought 679 acres with a 4,700-ft. water frontage, and will erect a shipbuilding plant, including a 1,000-ft. concrete or stone dry dock.

Rice & Hutchins, 6 High St., Boston, Mass., will erect a 4-story and basement, 50x203-ft., shoe factory at South Braintree and install a 150-H.-P. engine and 200 H.-P. in boilers.

T. Millen & Co., Wayland, N. Y., makers of Portland cement, will double the capacity of their dry kilns. The iron work has been contracted for and the buildings will be erected in the spring.

The Bellefontaine, O., Foundry & Machine Co. has been incorporated, with a capital of $50,000, to make hydraulic and pneumatic machinery, and will erect an 85x100-ft. foundry, 95x100-ft. machine shop, 38x75-ft. forge shop, etc. A 50-H.-P. power plant, with generator and motors, will be installed.

The Crabbs Reynolds-Bell Grain Co., Lafayette, Ind., will erect an elevator and install an engine of about 80 H.-P. and a 66-in.x16-ft. boiler.

BUSINESS NOTES.

The Libbe Engineering & Construction Co., Ltd., Toledo, O., has equipped a temporary shop for making sewer and trench machines.

The Ball Engine Co., Erie, Pa., reports the following among recent orders: A 125-H.-P. engine for the electric plant of the City of Farmville, Va.; a 100-H.-P. engine for the Lord & Burnham Co., Irvington, N. Y.

Dodge & Day, of Philadelphia, have been commissioned by the Heating, Ventilating & Foundry Co., of Pittsburg, to equip as engineers their plant at Wheeling, W. Va.

The Sprague Electric Co. reports among recent sales of direct-current apparatus the following: Twenty 200-Kw. turbine generators, three 75-Kw. generators and four 20-Kw. generators to the De Laval Steam Turbine Co., Trenton, N. J.; a 200-Kw. belted type and a 200-Kw. engine type generator to H. O. Wilbur, Philadelphia; a 200-Kw. engine type generator to the Otis Elevator Co., Yonkers; a 200-Kw. belted type generator to W. D. Ewart, Chicago; a 40-Kw. and two 35-Kw. belted type generators to the Criterion Hotel, New York; a 75-Kw. belted type generator to C. Poyet, New York; a 50-Kw. belted type generator to the American Express Co., Chicago; two 3-H.-P. round type motors to the West End Theatre, New York; eight 8-Kw. generators, six 5-H.-P. and four 1-H.-P. motors to the Fisher Motor Vehicle Co., Hoboken, N. J.; a 40-H.-P. medium speed motor to J. F. Perkins Co., Brooklyn; a 15-H.-P. S. S. type motor to L. W. Pond Machinery & Foundry Co., Worcester, Mass.; a 40-H.-P. belted type motor to the Miehle Printing Press Mfg. Co., Chicago; two 20-H.-P. M. S. type motors to the Sigourney Tool Co., Hartford, Conn.; a 17-H.-P. S. S. type motor to the Martinique Apartment House, New York; two electric hoists each to the Phoenix Iron Works, Phoenixville, Pa., and the Michigan Alkali Co., Wyandotte, Mich.; an electric hoist each to Landis Tool Co., Geiser Station, Pa.; American Car & Foundry Co., Berwick, Pa.; Scranton, Pa., Supply & Machinery Co.; Pond Machinery & Tool Co., Plainfield, N. J.

The Engineering Record is published every Saturday at 21 Park Row, New York. Its opinions on technical subjects are either prepared or revised by specialists.

Subscriptions are received and single copies supplied by the International News Company, Breams Building, Chancery Lane, London.

The subscription rate is $5 a year for the United States, Canada and Mexico, and $6 for other countries in the Postal Union. Remittances should be made by check, New York draft or money order in favor of The Engineering Record. No responsibility is assumed for payments made otherwise, except those for subscriptions to the International News Company.

Standards of Measurement.

Very close to the foundation of the structure of civilization lie the principles of standards of measurement, measures of value, space, weight, and of any and all other quantities and forces which form the basis and substance of commercial intercourse. Even among the uncivilized, among peoples with the crudest institutions, some standards of measurement, however imperfect, are found; and one of the best criteria of a people's advancement in civilization is the degree of perfection to which it has carried its standards. But the greater the progress and enlightenment, the greater the achievement in the arts and the more multiplied the industries of a nation, the more intimately do its standards become interwoven into all the processes of its life and the more difficult becomes a radical change. Such a change has been debated in this country for a century, and that the issue is not a dead one is indicated by the length of time and the animated discussion given to the matter in the recent annual meeting of the American Society of Mechanical Engineers, as well as by other evidences.

That there is yet much opposition to the adoption of the metric system, on the part of a class of men whose operations would be very vitally affected by the enforcement of a new set of standards was quite apparent in the meeting. Many expressions of opinion have been made by individuals and by organizations, but there is a feeling in some quarters that much of the loudest talking and most voluminous writing, on both sides of the question, has been done by a comparatively small number of persons and that many of those most deeply concerned have, for various reasons or without reason, abstained from statements of their positions. Why this indifference or apathy on so vital a question? Is it not that there exists a deep-seated conviction that neither coercive legislation nor any other sort of law-making can force such a change upon a people any more than imperial decree could change the language of a race?

The question affects the whole people and enters as far into the ordinary relations of life as, perhaps, any that could be raised; it has a practical interest for every man, woman and child of the population. Why, then, should it not be settled by the people? We believe, however, that there is no provision for such a popular referendum, and the matter is in the hands of Congress in the form of a bill. But whether the question be printed upon the ballots and answered at the polls or no, it, after all, will be the people who will give the final and practical answer. The metric system has had so large a place, from time to time, in engineering discussions and publications that it has become wearisome, and so we hesitate to mention it again; but some questions were raised by the authors of papers and the speakers at the meeting of the American Society of Mechanical Engineers which do not seem to have been answered to everybody's satisfaction. Will the metric system, if adopted, supplant the existing system, even if forced by compulsory legislation? If it will, how long must the transition period be? If it has taken so long a period to advance the system even as near to adoption as it has now come, is it to be expected that the assimilation of it in daily use will be so rapid as to be accomplished within a few years? What will the common people gain by the change; how great a benefit will accrue to any class, trade or profession? How much will it cost to introduce and establish the new system? For it will cost something. All prejudice aside, would the proposed units of measurement be as convenient as those that we now use? What, for example, would be given in exchange for our convenient 1-foot and 2-foot rules which are so common a piece of pocket furniture?

Let us remember that declining the proposed standards of measurement does not mean the rejection of all the advantages of the decimal system of computation. Decimal subdivisions can be applied to existing units with any desirable degree of freedom, and are so applied whenever distinct advantages are to be gained by so doing. Instances of this are so common as to require no mention by way of illustration.

A sentence quoted in one of the papers at the above mentioned meeting is a fitting theme for prolonged and earnest contemplation. The sentence is this: "Measures of length are irrevocably tied to the past." Think over it for a while and see what a change of standard means along the lines of thought which this statement will suggest. There is another stumbling block in the path of the suggested system, it may be but a trivial one, namely, that the names of the units being of Greek and Latin derivation, do not readily fit the mouths of Anglo-Saxons. Those who have hesitated to espouse the metric system have sometimes been accused of being in the rear of modern progress, but it has been suggested recently that while the Anglo-Saxon peoples lead in manufactures and commerce, the units of measurement which they employ will be accepted by the nations with whom they trade.

Instead of adopting another system of standards which, judging by the experiences of other nations, will, at least for many years, increase the number of standards in use rather than supplant existing standards, would it not be more sensible to direct our energies towards the perfecting, the wider dissemination and the surer establishment of the English system?

The Assouan Dam on the Nile was completed December 10, when the Duchess of Connaught laid the last stone. The foundation stone was laid by the Duke of Connaught February 12, 1899. The dam was finished ahead of contract time at a total cost of about $12,500,000. Its greatest height is 131 feet, width on top 23 feet and length about 1¼ miles.

The Meeting of the American Society of Mechanical Engineers.—II.

In the report last week of the December meeting of the American Society of Mechanical Engineers, much in the way of brief reviews of some of the papers and of digests of the discussion of those of likely interest to the readers of this journal was crowded out owing to lack of space. While the convention must always remain one that was devoted largely to a serious consideration of the adoption of the metric system, there was the usual collection of papers of varied scope. Before taking up any of these topics, however, mention may well be made here of the disposition that was finally made of the metric system question. Toward the close of the Friday morning session a motion was passed instructing the council to obtain by letter ballot from the voting membership of the Society an expression of opinion regarding the subject. It is intended that both Mr. Halsey's paper and a record of the entire discussion be issued, and that an answer be requested as to whether or not the member is in favor of the House of Representatives bill providing that the metric system shall be adopted in the business transactions of all departments of the Government and as to whether or not he favors the provision that the system shall subsequently (in 1907, according to the present bill) be declared the legal one.

Prof. Reeve's paper on the entropy analysis of the Otto cycle in gas-engine work was presented to call attention to the advantages and ease of submitting records of tests of gas engines to the temperature-entropy diagrams and to show among other things that the combustion in the Otto cycle takes place in a definite time, after which there is no further development of heat and that there is an interchange of heat between the working fluid and the cylinder walls, similar to that taking place in the steam engine. He believes no observer of a gas-engine test has done his proper duty until he has submitted his results to the entropy analysis.

Mr. J. M. Barnay's paper on a 44-foot lathe described a machine, for which some 480,000 pounds of cast iron were used in construction and which is driven by means of a compressed-paper friction roller, 18 inches in diameter, bearing on the 15-inch rim of the large face plate, which is 30 feet in diameter. The machine has cut 64⅓ cubic inches of cast iron per minute, and on the basis that 0.35 horse-power is equivalent to 1 cubic inch per minute, the friction roller succeeds in transmitting an effective power of 22½ horse-power.

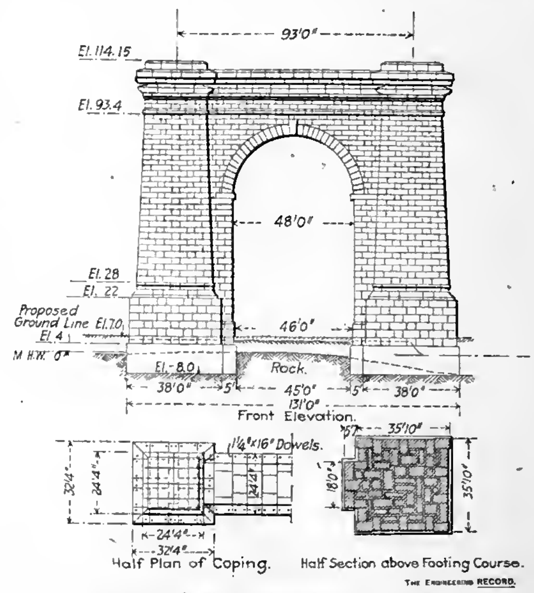
The paper presented by Mr. Chas. T. Porter on finer screw threads argued that the existing system of threads reduces the area of cross-section of the bolt unnecessarily, and that the steep inclination allows the nut to jar loose easily. He advocated a finer thread to avoid these two evils, and incidentally to secure a greater strength to resist stripping. He submitted a table of his system of dimensions for bolts ¼ to 6 inches in diameter with 24 to 6 threads per inch instead of the present standard of 20 to 2¼ threads per inch.

In addition to what has already been noted in the foregoing and in last week's account, a number of subjects were considered as topical discussions, including that of oil burners and that of oil separation from steam. A number of members expressed the belief that generally speaking all burners were good, and that if trouble arose in their operation it was not unlikely due to too small a furnace or an improperly designed one. Prof. Arthur L. Williston called attention to the fact that the necessary storage of oil sometimes increased the cost of fire insurance to such an extent as to favor the use of coal. On the subject of oil separation, Mr. David J. Lewis, Jr., said that he had good success with the baffle-plate type of separator, but it was necessary to clean the plates at more or less frequent intervals. For this purpose the plates were first washed with benzine and then boiled in a solution of soda and potash for 10 hours. He considered it essential that the steam be received as hot as possible, and that therefore the separator be placed between engine and feed-water heater.

Construction of the Blackwell's Island Bridge Masonry.

Bridge No. 4 crosses the East River between 59th and 60th Streets, New York, the western approach being at grade at Second Avenue, borough of Manhattan, and the eastern one at grade at Jackson Avenue, Ravenswood, borough of Queens. The center line of the bridge is a straight line running nearly northwest and southeast, and is about 8,338 feet long including approaches of about 1,100 feet in Manhattan and 3,440 feet in Queens. The superstructure is divided into five spans of a total length of 3,673.5 feet between anchorages, and includes a west channel span of 1,184 feet, an east channel span of 894 feet and an island span of 630 feet, all cantilevers, as was necessitated by the depth of water, the strong current and the heavy traffic in the river. For a length of 400 feet the bridge has a clear height of 135 feet above mean high water, and both approaches have a uniform grade of 3.41:100. The bridge capacity is two elevated railroads and four trolley tracks, two roadways and two sidewalks. The trusses are 170 feet deep and will be much heavier than those of any bridge ever yet built, not excepting the Forth bridge, the chords having maximum cross sectional areas of about 1,000 square inches. The total estimated weight of the superstructure is about 100,000,000 pounds and the estimated cost is $12,500,000, including $3,000,000 for the right of way. There have been some changes made in dimensions of the superstructure, but it still corresponds in most respects to the data published in The Engineering Record of March 16, 1901.

Preliminary surveys were completed in June, 1899, and thirty-six diamond drill borings were made to a depth of 10 feet or more in bed rock at the pier sites and were completed in August, 1900. The lengths of spans and locations of piers were determined by triangulation from a base line 1,671.03 feet long intersecting the center line of the bridge nearly at right angles on the high ground in the center of the island. The base line extended 1,122.05 feet north of the center line and 548.98 feet south of it, each portion being made one side of a triangle for the determination of the distance across each channel. The base line was measured three times with a difference of only 0.002 foot. The angles of the four main triangles were measured 100 times each with a transit having a 10-inch circle graduated to 10 seconds. The variations of the sums of the angles in each triangle from 180 degrees were 0.1—0.35—2.7 and 4.9 seconds. The distances across the channel were com-



Pier No. 4, Ravenswood Shore.

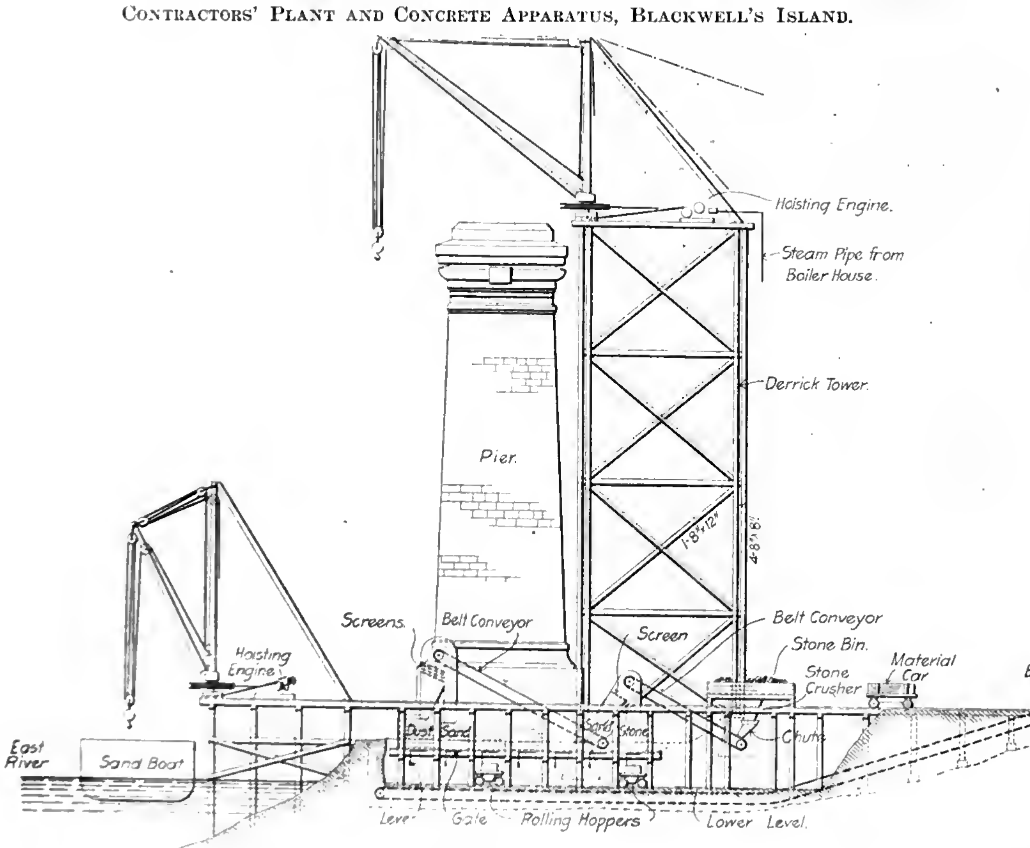
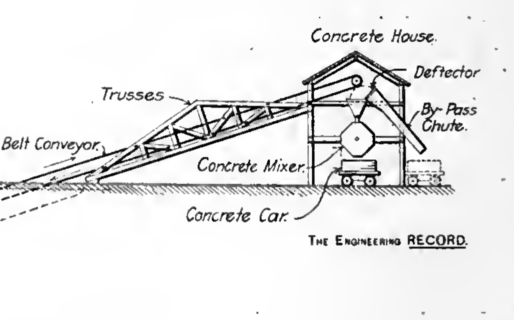
Contractors' Plant and Concrete Apparatus, Blackwell's Island.



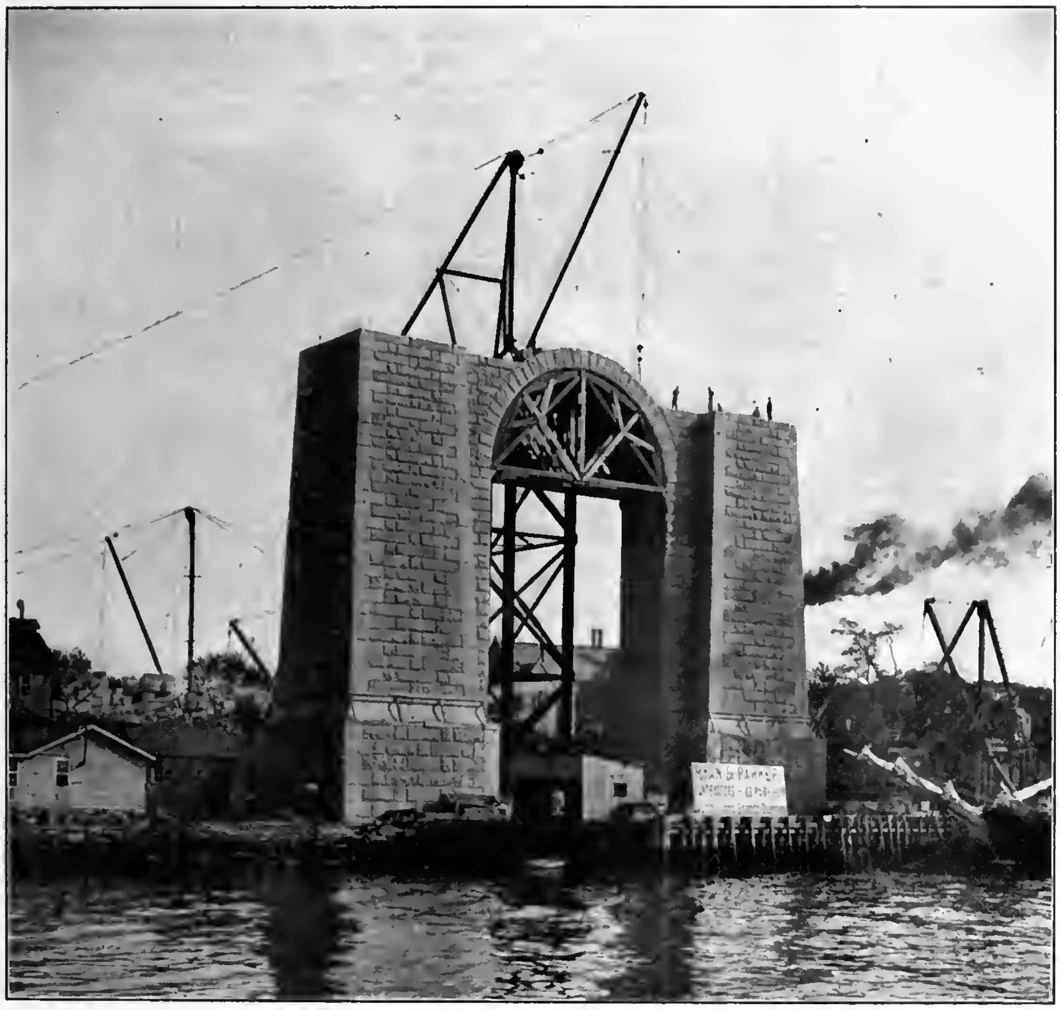


PARTIAL ELEVATION OF BLACKWELL'S ISLAND PLANT.

puted from the triangles and from them the length of one portion of the base line was calculated and checked the measured distance within 0.009 foot.

The base line was measured with a 200-foot steel tape, with a spring balance and adjusting screw, supported in a straight, but not horizontal line, at intervals of 25 feet, on pegs set in holes ¼ inch apart on vertical wooden rods which had steel points resting on line stakes and were clamped at the top to the heads of special extension tripods. At each end of the tape there was attached a brass chain, which passed over a saddle in an adjustable tripod and was fastened to a pin driven in the ground. The end of each measurement was marked on a paper pasted to the top of a horizontal 6x6-inch steel plate clamped to a vertical iron bar driven firmly in the ground. The tape was a steel ribbon 0.125 inch wide and 0.025 inch thick which was compared with the New York State standard at Albany and assumed to be correct at standard temperature under a tension of 11 pounds if supported throughout its entire length, or under a tension of 12½ pounds if supported at intervals of 25 feet. The ends of the base line and other reference points, were marked by monuments, nine of which were set in the center line of the bridge. These are vertical granite pillars, 12 inches square and 3 feet high, set in rammed earth with the dressed upper surface just above grade. The center point is a ⅛ inch hole drilled in a square brass plate which has a dowel pin 6 inches long wedged and cemented into the stone. The transit was supported at the ends of the base line on platforms 12 feet high with a separate outside platform for the observer and a wooden box reaching down nearly to the ground to enclose the plumb bob and protect it from the wind.

There are four main piers and two anchorage piers, each made with two separate shafts connected by a thick transverse wall, all substantially shown in the elevations of pier No. 4, which is on the Ravenswood shore of the river. The other piers vary somewhat in height and bottom dimensions according to the depths of the foundations, and the anchorage pier shafts are only 20 feet square on top and are connected by transverse walls only 12 feet thick. The shafts are battered 1:24, the belt course below the coping has a projection of 4 feet and the full centered arch has a clear span of 48 feet and voussoirs 4 feet deep in the ring courses. All the foundations are carried down to solid rock in open pits, those of the main piers being 6 to 12 feet in depth and easily kept dry by moderate pumping. The surface of the rock is leveled and concrete footings built up to the grade where the rock faced ashlar of the sub-base commences. The face stone is coursed rock-faced granite with point-dressed quoins. The cap and moulded base courses are four-cut work. The arch soffit and the faces of the arch ring are rock faced. The backing is concrete except in the shafts on the main piers, where it is limestone.



Pier No. 2, Blackwell's Island.

There are, in the six main piers, about 22,000 yards of granite, 22,000 yards of limestone backing and 15,000 yards of concrete. The contract for them was let in June, 1901, to Ryan & Parker, for $745,547. Excavations were made to rock inside sheet piling and cofferdams for both the island piers and for the pier on the east shore of the river, and were easily kept dry by pumping. A plant for storing materials and mixing and handling concrete was established near pier 2 on the west side of the island, to serve piers 2 and 3, and another plant was established on the east shore between pier 4 and the anchorage pier to serve both of them. A third plant will be established on the west shore to serve pier 1 and the west anchorage pier. In all these plants the arrangement and system of operation are different and are especially adapted to secure a large output and rapid and efficient work with the greatest economy of labor.

All the stone is brought from the contractors quarries, the limestone from Cobleskill on the Delaware & Hudson Railroad, and the granite from Crotch Island on the coast of Maine. It is stored on Blackwell's Island between piers 2 and 3, and is there cut by a large force of stone cutters. There is about 15 per cent. waste which is all put through a Gates crusher to make broken stone and sand for the concrete and mortar. The spawls are delivered by derricks and cars to the crusher, which discharges on a Robins belt conveyor. The conveyor delivers to an elevated screen of ¾-inch mesh, which is set at an angle of 45 degrees. The material which the screen rejects falls down a chute into a storage bin and is used for concrete. The material which passes through the screen falls on a second conveyor which elevates and discharges it over a set of four ⅛ inch mesh screens set at an angle of 45 degrees. The fine stuff that passes through the screens is sold for top dressing for macadam roads and the remainder falls into a chute which delivers it into a storage bin, from which it is taken as required for use as sand. The grains are very sharp and hard and tests of briquettes made with them are superior to others made with standard sand. The sand and broken stone thus provided are not sufficient for the demand when large quantities of concrete are being made and sand and gravel are delivered by boat and kept in storage to supply the deficit.

The storage and handling of materials on the island is very ingeniously and efficiently arranged. A pile dock is built close to pier 2, projecting far enough into the river to receive schooners and barges at low water. On it is built a cement storage house and the deck is continued to make a horizontal platform 21 feet wide and 23 feet above mean high water, extending 100 feet back from the shore line. A stiff-leg derrick with a 30-foot boom on the outer end of the dock unloads stone, sand, broken stone, gravel and cement from the boats to cars which run on two tracks on the platform, parallel to the bridge axis, and dump into storage bins under the platform, alongside those for the products of the stone crusher. The bottoms of these bins are about 6 feet above a low level track parallel to those on the dock platform and have holes about 1 foot square, closed by horizontal steel plates, operated by levers. When these holes are opened, the contents of the bin are delivered to measuring hoppers mounted on trucks on the low level track. The hoppers are run under any bin, are filled, and discharge their measured contents through the open track platform on a Robins belt conveyor parallel to the track. At the river end of the belt the cement bags are emptied on its surface and the hoppers are so proportioned that one hopper of sand, one hopper of broken stone and nine bags of cement are sufficient for one two-yard batch of concrete.

The belt conveyor is about 30 inches wide and about 200 feet long and passes through a trench and out from under the land end of the platform at an inclination of 20 degrees upwards and is carried over a roadway on the surface of the ground by a 50-foot span bridge having two wooden Fink trusses 5 feet apart. The upper end of the belt is supported on a tower about 30 feet high and 15 feet square in which the 2-yard Carlin concrete mixer is set. The belt discharges its contents directly through a funnel into the mixing box. The funnel is swung out of the way, the box closed and revolved until the concrete is mixed, when it is dumped into a scale box on a car on the surface tracks and is hauled by mules to either pier 1 or 2. With one man to attend the mixer and one man to put sand, stone and cement on the belt conveyor, this plant will mix 75 yards of concrete in 8 hours; with a third man to attend to the cement while the second attends to the sand and stone the capacity is doubled. The concrete mixer is driven by an 8x12-inch engine, and the engine, conveyors and rock crusher and six mason's and stone cutter's boom derricks are operated by steam from a 120 horse-power boiler.

A very ingenious arrangement has been devised by which, when the belt conveyor is not in use for supplying the concrete mixer it can be utilized for distributing sand and broken stone from the screens to remote bins beyond the reach of the chutes. When concrete is being mixed the materials are thrown off from the upper end of the belt and striking against a deflection board fall into the mixer funnel. The deflector can be revolved into such a position as to close the opening of the funnel and at the same time serve as an apron to a by-pass chute. Then the broken stone or sand carried by the belt falls on it and is discharged past the mixer to a car on the surface tracks and can be run back over the upper platform and dumped into any of the bins which ordinarily receive the sand and gravel delivered by the boats.

Pier 2 has been built by a stiff-leg derrick with a 40-foot mast and 80-foot boom set on a tower 36 feet square and about 100 feet high. The tower has a vertical post at each corner and one in the middle of the long side, on the center line of the bridge, to receive the derrick mast, each of which is set on concrete piers 8½ feet high and 8 feet square at the bottom. Each post is made of four 8x8-inch pieces with lap spliced butt joints. Each face of the tower is braced in four vertical panels by 8x12-inch timber, and at each panel there is horizontal diagonal bracing. The top is floored over and the two-drum Lidgerwood hoisting engine is located there. Access is had to the top of the tower by a flight of stairs and the derrick boom commands all parts of the tower. The arch voussoirs were set on five falsework trusses made of 10x12-inch timbers and covered with 3-inch lagging. They were supported on corbels left temporarily projecting from the faces of the stones in the skewback course. After the arch was sprung and the centers removed these corbels were cut off and the faces dressed smooth to correspond with the rest of the masonry there. The face courses of the pier shafts were made of handsome stones weighing up to 16 tons each and from 2½ to 3½ feet thick, alternate headers and stretchers. The stretchers were 6 or 8 feet long and were lifted by dogs engaging holes in the centers of the long sides. In order to avoid permanent dog holes in the faces of the stretchers a projecting lump or boss was left temporarily in the face of each and the dog hole was sunk in it. After the

stone was set this boss was cut off and a perfect face was secured for the stone. After the completion of pier 2 the engine and derrick will be removed from the top of the tower and the latter will be moved across the island and used for the completion of pier 3, which has now been built up to a height of about 40 feet above the water.

At the east end of the bridge, the contractors have built a temporary pile dock with its face about 100 feet beyond the face of pier 4, and from it there extends on the center line of the bridge, a pile and trestle platform about 20 feet wide and 600 feet long which slopes up on a 4.6 per cent. grade to a height of about 30 feet above the ground over the east anchor pier. This platform is carried over Vernon Avenue, adjacent to the anchor pier, by a three-truss wooden bridge and it has two standard gauge tracks from end to end. Scale boxes on flat cars are pulled up the tracks by a cable and hoisting engine at the head of the incline and return by gravity. Underneath the platform, near the upper end are six flat-bottomed storage bins 8 feet wide, 10 feet deep and 30 feet long. They are filled with sand and gravel or broken stone delivered by boats and dumped from cars on the upper tracks, and have horizontal steel gates in the bottom, through which their contents can be drawn into side dumping measuring cars on six 30-inch transverse tracks under the bins. These tracks extend beyond the bins and between their ends, on the arc of the circle described by the 60-foot boom of the concrete derrick, are four 4½x5½-foot pits, 4½ feet deep. Charging boxes are set in these pits and bags of cement from the adjacent store house are brought to them by hand trucks on a run way and enough put in one of them for one batch of concrete, a car of sand and a car of broken stone are then brought from the bins on the track both sides of the pit, and, their contents being dumped into the box, the latter is lifted by the derrick, swung around and dumped into the concrete mixer.

Concrete is delivered by the mixer into scale boxes on cars which are pulled up the incline empty and return loaded by gravity to pier 4, where they are hoisted by a derrick for each shaft. These derricks are carried up independently as the masonry rises and dispense with the necessity of a tower and stiff-leg derricks at this end of the bridge. Alternate storage bins are filled with sand, the others with broken stone and the delivery cars dump on either side so that each pit is supplied with sand from one side and with stone from the other side. The bins have their floor-beams about 6 feet clear of the ground and are supported on trestles set on the rock bottom of an excavation made in the side hill to provide for the delivery tracks and mixing pits. The inclined platform is carried on the bin posts and elsewhere is supported on ordinary framed trestle bents with mud sills on the surface of the grounds. A force of about 250 men is now at work on the piers and it is expected that they will be completed in about one year. The concrete buckets have a capacity of 1.7 yards and can make a round trip every five minutes. Over 175 yards of concrete has been mixed and delivered by this plant and put in pier 4 in one 8-hour shift, and it is expected that when concrete is delivered simultaneously to the anchorage pier and pier 4 this output may be nearly doubled.

The stones in the coping course of pier 2 have maximum dimensions of 9½x3½x4½ feet and weigh as much as 25,000 pounds, an amount which was thought to be too large to lift 125 feet at the extremity of the 80-foot boom of the tower derrick, although it was proportioned for 20 ton loads. These stones were therefore delivered from the yard on cars to the short boom of the dock derrick, transferred by it to a transverse track on the low level dock and taken to the middle of the tower face. There they were lifted with a comparatively short radius by the long boom of the tower derrick which was then in the most favorable position, bisecting the angle of the stiff legs and pulling against both legs and the four guys, two in the lines of the legs and two at a wider angle. After the stone was lifted to the top of the tower by chains attached to dogs, it was set down on the masonry, picked up by Lewis bolts and swung carefully to place at an elevation only just clearing the top of the pier, so that in case of any breakage it would not drop far.

The granite is of a very uniform, warm gray color, is coarse grained and has a high crushing strength. It is quarried in regular rectangular blocks with sharp true edges and straight sides and of any required dimensions. The quarry reaches from the water's edge to the top of a knoll about 125 feet high. The strata worked are very regular, from 1 to 12 feet in thickness and are intersected by two open fissures, normal to the surface and about 500 feet apart, which define the limits of the quarry. The dip is about 20 degrees and the surfaces in contact are entirely separate and very smooth planes. The strata are uniform and continuous and fifteen or twenty of them are being worked upwards from the lower edges, giving faces of from 1 to 12 feet high. Where the superimposed rock is stripped off from a wide surface of a stratum it will split across in long straight lines, but where it is heavily loaded with upper strata extending nearly to the working face it splits in curved lines convex toward the pressure.

Crotch Island Granite Quarry.

A diagram of the method of working is shown on the sketch of the quarry plan, not made to scale or true dimensions, but merely indicating the operation. 1-2-3-4 and 5 are successive strata of increasing height and from 5 to 12 feet thick. Suppose that stratum 4 is 9 feet thick and it is desired to quarry from it stones 12 feet long. On the required line B-H a pair of holes about 12 inches apart and 9 feet deep are made at D with a compressed air drill and black powder is fired in them, they are swabbed out, recharged and refired, and so on several times until a crack has been opened from J to L. Another similar pair of holes is made in the line of the crack about 40 feet away at E and they are similarly fired. Holes are drilled at G-H and so on, and the crack is produced as far as desired, extending everywhere through to the stratum below. Holes 9 feet deep are drilled 12 inches apart in two rows 12 inches apart from A to B, adjacent to the open seam which bounds one side of the quarry. The pair of holes nearest A are heavily loaded with dynamite and fired, then the next pair are fired, and so on. Each blast pulverizes the granite between and close to the holes and throws the fragments so far that these blasts are fired at night when only the two men in charge remain on the island. When the whole set of holes has been fired a channel has been formed about 24 inches wide which extends through the stratum from A to B and gives a free face. The slab A-B-H-M, 12 feet wide, 9 feet thick, and perhaps 300 feet long, is thus detached from the stratum, but is not moved more than the fraction of an inch from its original position. Blocks of any required width are laid off by lines K-K-K, etc., of small holes, which are drilled by hand, and the stone is split along them by the regular plug and feather method.

The method of removing these blacks is ingenious. Dog holes are made in them and the main line from a derrick is attached and a strain is put on by the engine, but does not move it. The crack B-H is perhaps ⅛ to 1/16 inch wide, and in it, opposite the center of the blocks, are poured two cups of thick black oil at points about a foot apart. Between these points is poured a handful of black powder, which is covered with dirt, and has a fuse attached. The powder does not spread beyond the oil line, and so is confined in a thin sheet, filling the crack from top to bottom. When the fuse is lighted there is a light explosion which does not break the stone, but suffices to kick it out of its place and thus started it is easily pulled by the derrick line, over the smooth steep slope of the underlying stratum to a point within reach of the derrick boom. There it is split and cut in any required sizes by plug and feather, and the pieces are loaded by the derrick on cars lowered down inclined track by cables to the two docks where other derricks load them on schooners for shipment.

All the derricks are swung by bull wheels and are operated by hoisting engines driven by compressed air, which is furnished by a McKiernan compressor. Steam is supplied by a 200 horse-power boiler, and air is piped all over the quarry. There are ten guyed derricks, most of them with 10-ton 50-feet booms, and they and the inclined cable roads are operated by fifteen Lidgerwood and Mundy hoisting engines. With a force of about 140 men the output of the quarry is about 1,500 yards of stone a month, all of it practically without waste. The larger sizes are all required for the contractors work in New York, but that which is cut from strata less than 2½ feet thick is sold by the ton for miscellaneous building purposes. This quarry can furnish stone up to 12 feet in thickness, and of any desired length and thickness, the dimensions being limited only by the possibilities of handling. On one occasion a single stone weighing 2,500 tons was split off from the face of the stratum, kicked free by one pound of powder and dragged 120 feet to the derrick boom, as described, and when cut up made sufficient large blocks to load four schooners and did not leave a single yard of waste.

The quarry derricks are rigged in a special manner, as indicated in the diagram. The hoisting line is a single 1½-inch wire rope reeved through a single sheave at the point of the boom. Thence it is led around a sheave at the foot of the mast and thence to the heavily loaded three-sheave lower block of a six-part vertical tackle. The upper block of the tackle is fastened to the top of the mast, and its fall line leads over a single sheave on the opposite side of the mast and thence down around a bottom sheave and to the engine drum. This arrangement provides a hoist line with a single part, free from blocks, which, for hauling the immense blocks of stone down the slope to the boom radius is often extended by another line of the required length to reach as far away as necessary. The end of this line is hooked to the ring on a light return line and the latter being led around an anchored sheave beyond the block, is wound up by the capstan head of the hoisting engine and pulls the heavy hoist line up the slope to the required position, where it is detached and secured to the stone which it pulls down with the main tackle.

The bridge is being built by the Department of Bridges, New York City, Mr. Gustav Lindenthal, commissioner, and Mr. Oscar Erlandsen, assistant engineer in charge.

The "Clean Street Ordinance" of Chicago, passed February 18, 1901, provides for the use of metal receptacles for garbage and ashes, and the abolition of wooden boxes. In the first efforts to enforce this ordinance it was found necessary to call upon the police department for assistance, and three officers were assigned to each ward superintendent, a total of one hundred and six officers being used for this work. Mr. M. J. Doherty, superintendent of streets, states in his last annual report that with the assistance of these officers there were distributed from May to September, 1901, inclusive, 314,430 copies of the ordinance, 99,939 notices to provide metal receptacles, 82,489 notices to remove wooden garbage boxes, and 15,854 notices to remove manure boxes; 795 arrests were made for non-compliance with the ordinance. Within two months after enforcement of the ordinance, wooden garbage boxes, with but few exceptions, were removed, and 218 cement, stone, or brick manure vaults built.

Submerged Steel Pipes for the Jersey City Water-Works.

A new water supply of 50,000,000 gallons per day will be provided for Jersey City, N. J., by the works now under construction at a contract price of nearly $7,000,000, as described in The Engineering Record of July 21, 1900. A masonry dam at Boonton, N. J., which will be over 110 feet in extreme height and 3,400 feet long on the crest, will impound 12,660,000,000 gallons of water. From this reservoir water will be delivered through a steel and masonry conduit nearly 23 miles long. The masonry portion of the conduit is to be built at hydraulic grade and have a capacity of 70,000,000 gallons a day. There is in all about 94,000 feet of 6-foot riveted steel pipe under pressure up to 100 pounds per square inch.

Each length of pipe is made of a single sheet of steel with a lapped longitudinal joint having a double row of 1⅛-inch rivets, and the lengths are put together with telescopic taper joints. The circular seams have single rows of rivets, and all seams are caulked inside and outside with pneumatic tools. The submerged pipe at the river crossings is made with 25-foot sections, field-riveted together, each composed of five 5-foot lengths shop-riveted together. Elsewhere four 7½-foot or five 6-foot lengths are shop-riveted together. The 25-foot and 30-foot sections are delivered along the line by special trucks which hold the pipe on pairs of longitudinal skids swung low between the axles. These trucks are drawn by four or more horses. Before shipment the sections are dipped in a bath of hot asphalt and are all consecutively numbered and delivered in order, although many sections are duplicates. All vertical and horizontal deflections are made with flat curves by cutting the forward end of a length of pipe to a bevel while the rear end is cut square. The estimated weight of the steel pipe is about 30,000,000 pounds and it is being manufactured and laid in several separate contracts awarded to the same firm.

At the Hackensack River crossing there is approximately 840 feet of pipe 11/16 inch thick which weighs about 600 pounds per linear foot and is submerged to a maximum depth of about 40 feet. It is a continuous rigid section, without flexible joints, riveted together on one shore, with vertical curves corresponding to the plotted profile, and laid in an open dredged trench 70 feet wide over all with a bottom width of 15 feet and side slopes not steeper than 4:1. The method of laying and protecting the pipe is somewhat unusual and has been executed rapidly and successfully. The pipe was riveted together complete on shore, enclosed in a continuous protecting tube of concrete, drawn across the river under water and suspended just clear of the bottom by the aid of floats and trestles.

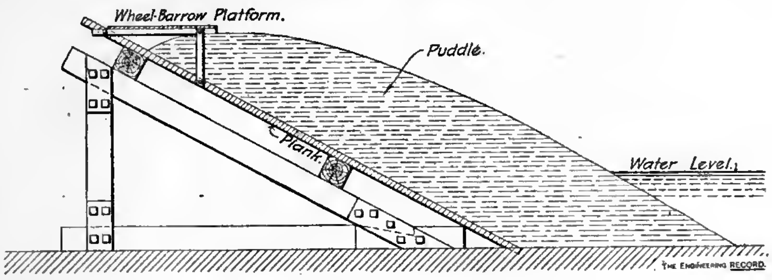
The first section, 25 feet long, had the forward end closed with a water-tight steel bulkhead, pointed in front, and was suspended at an angle of about 20 degrees from the horizontal by tackles from a double pair of sheer legs. It was guyed securely in a convenient position and rings of armored concrete 5 feet long were slipped over the upper end, their adjacent ends cemented together and the space between the rings and the pipe poured full of grout. Lines attached to the pipe were wound up on the drum of a hoisting engine and pulled the pipe forward over the center line of its trench.

The total weight of the empty pipe and the concrete covering being about 40 pounds per linear foot more than that of the water displaced imposed only a moderate stress on the suspending tackles and allowed it to move easily. The forward end was carried in a loop of rope suspended under the bottom of a boat, and the rear end of the pipe was held back by tackles and supported by jacks on low timber blocking on shore, just above the water line. Another 25-foot section of steel pipe was then connected to the shore end of the first length and held in position by two boom derricks until the joint was bolted up. The rivets were then driven, the seams caulked and painted, five concrete rings slipped over the pipe and grouted, and finally the whole pipe was pulled forward. Other sections were added successively in the same way. The rivet holes required very little reaming and the 92 field rivets for one joint were driven in about 2 hours.

Assembling and Launching Pipe.

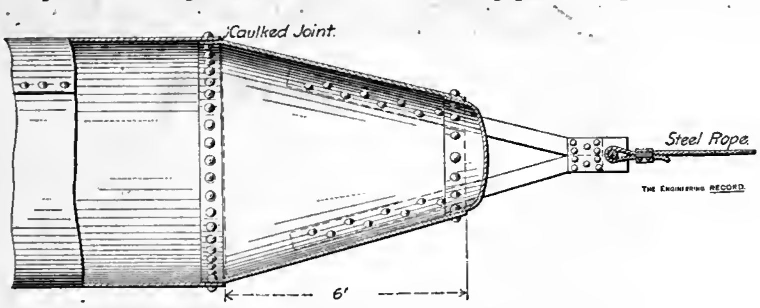
The concrete rings were put on and cemented and one complete 25-foot section finished and pulled forward ready for the next in 12 hours by a total force of about 46 men including the dredge crew. The concrete rings have an internal diameter of about 6.73 feet, external diameter of 7.70 feet, length of 5 feet and weight about 10,000 pounds each. They were made, at the site, of 2:5:9 Atlas Portland cement concrete mixed very wet and rammed into steel moulds. They are reinforced with welded rings of ½-inch square steel, 12 inches apart, and with six lines of ½ inch square twisted steel longitudinal rods. The pipe is laid everywhere with the longitudinal seams up and alternately on each side of the middle. The concrete rings rest on its upper side so as to leave a clearance of about 5 inches on the lower side, thus having an eccentricity of a little more than 2 inches. As the rings were successively slipped in place, each joint between abutting ends was covered by a thick rubber band 6 inches wide having its ends riveted to short transverse steel angles making flanges by which the band was drawn very tight, with two bolts. At the land end of the last ring, a temporary wooden collar was attached to close the space between the steel pipe and the loose ring and retain, until it set, the 1:1 grout which was then poured in to make a solid filling and cement the ring to the pipe.

Temporary piles in groups of four about 150 feet apart were driven both sides of the pipe and capped with transverse horizontal timbers



DIVERSION DAM.

just above the water level. In some cases these caps supported longitudinal rollers, one on each side of the pipe, on which the ends of the suspension ropes were wound. The rollers were 10-foot lengths of 6-inch gas pipe with cross holes through the ends for capstan bars which made it possible to hold, wind up or slack, the ropes. In the other cases the rollers were replaced by vertical screw rods passing through holes in the caps, one on each side of the pipe, with nuts bearing on washers on the caps. The ends of the suspension rope slings were secured to eyes at the lower ends of the rods. Between the groups of piles four canal barges were moored with their longitudinal axes in the vertical plane through the pipe and were used as floats to support the pipe while it was being moved across the river. From each side of each barge ropes were suspended to form



BULKHEAD FOR LAUNCHING PIPE.

slings passing under the bottom of the boat and carrying the pipe. After each successive section had been riveted on the shore end of the pipe and the concrete rings threaded on it, the slings under the floats were carefully adjusted to the same tension as those suspended from the pile caps, and the latter were then slacked off, completely so as to gradually throw the weight of the pipe entirely on the floats and release the stationary slings without changing the position of the pipe. Then the shore tackles were slacked off and snubbed carefully, and, if the pipe did not, as usual, move forward under its own weight, it was assisted by putting a pair of 20-ton differential screw jacks under the shore end to raise it free of the cribbing on which it was assembled and by pulling on two four-part tackles attached to the rear end of the pipe and to dead men between the end of the pipe and the river. The tackles were operated by a hoisting engine on shore near the concrete plant, and when the pipe was nearly completed the engine was taken across the river to wind up the line attached to the forward end of the pipe and pull it up out of the water, this being the only part of the operation which required much force to move the pipe.

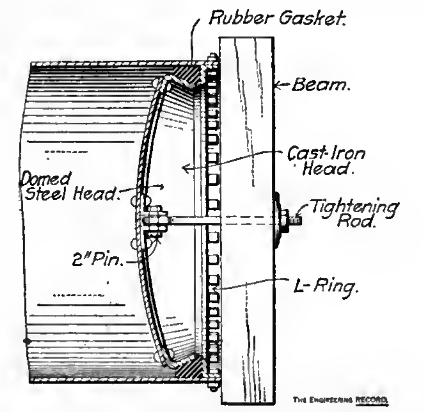
The wire hauling rope was attached to the forward end of the pipe by a 2-inch pin passing through a pair of jaw plates, to each of which was riveted a pair of 5x1-inch steel bars. These bars were riveted equidistantly to the conical part of the bulkhead which, together with a domed head 3 feet in diameter closed the end of the pipe. By this arrangement the tension was applied to the elements of the cone without eccentricity or danger of distorting the bulkhead.

As the net weight of the submerged pipe between supports was only about 6,000 pounds the stress produced by the moment of flexure was entirely negligible, considering the section of pipe as a tubular grinder, 6 feet in diameter and 150 feet long. It was considered of great importance to keep the pipe at all times in exactly the required vertical position, and to maintain equal stresses on all the slings. The former object was attained by frequently raising and lowering the pipe and locating its position by measurements checked with the distances on a profile of the bottom of the trench as plotted from soundings; the latter was attained by inspection of the ropes and testing their tension by feeling the rigidity.

As the pipe is a rigid tube fitted to the profile of the river bottom it was not parallel to it until completed, and its successive positions were determined by the location of the extremities, the shore end being fixed and the forward end movable. It resulted that the whole pipe revolved in a vertical plane around the shore end as a center, and that the weight and inclination of the portion of the rear end of the pipe above the surface of the water was generally sufficient to make it move forward by gravity when released, without pulling on the tackle provided to haul it across the river. The proper manipulation of the pipe in its slings was considered a very delicate and important matter and was successfully accomplished.

The principal advantages of this method of laying submerged rigid heavy pipe in long lengths are that all work is done on shore with plenty of room and complete stability; that it can be sunk and its weight adjusted without admitting water ballast or complicated temporary loading; that it is efficiently and permanently protected without back filling or rip-rapping; that it is kept at all times entirely free from the bottom so as to be easily handled and at the same time deep enough to clear passing boats and offer no obstruction to navigation; that it is uninfluenced by storm, flood or tides and that except during the brief intervals when it is actually in longitudinal motion it is firmly secured to solid pile bents. After the pipe was pulled entirely across the river and the forward end appeared above the surface ready to join the shore section, it was lowered to its final position on the bottom of the trench by men simultaneously operating all the pipe windlasses and screw adjustments. As the concrete jacket is considered ample protection and will hold it down if it is ever necessary to empty it for inspection or repairs, there will be no back filling or additional covering except that resulting from the silting and washing of the river bed.

On both shores of the river the ground is low and soft and special methods were devised for laying, supporting and covering the steel pipe. On the west shore the embankment around the pipe is back filled by side dump cars drawn by a locomotive, bringing spoil from a cut which the contractor is making for the Delaware, Lackawanna & Western Railroad. The



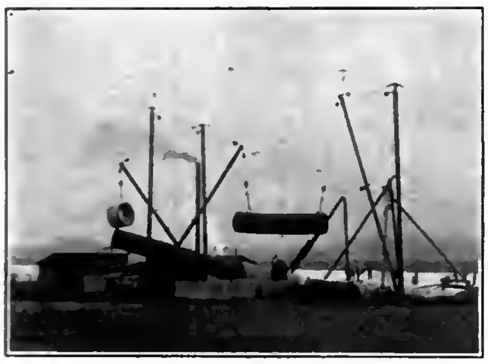
BULKHEAD FOR PIPE TESTING.

track is laid on top of the pipe and none of the fill is made by hand. On both sides of the river the line is carried for several thousand feet over marshes where it was necessary to first build a clay bank causeway. Enough clay was dumped into the causeway bank on the east side of the river to fill it up to the level of the center line of the pipe and to leave extra material on the sides so that after the excavation has been made for the pipe and it is laid, riveted and tested, there will be sufficient earth there for all the required covering of a minimum depth of 3 feet.

In some places the swampy ground was sheet piled and with constant heavy pumping a trench was dug, in which 3 feet of clay were filled to make a bed for the pipe. On the east side of the river there is a power house with a Rand air compressor from which compressed air at about 90 pounds is piped along the line to operate pneumatic caulkers, reamers and hammers. Holes are left in the top of the pipe about 50 feet apart to insert the pressure hose for driving rivets inside, and are afterwards closed by screw plugs.

After being riveted and caulked in the trench the pipe is tested in sections of 5,000 to 20,000 feet by hydrostatic pressure of 120 pounds per square inch, applied with a contractors steam pump. Generally the ends of the section under test are closed by the regular valves of the pipe line, but when these are not conveniently located for this purpose the ends are closed by a special removable bulkhead patented by the contractor. This consists, as shown in the sketch, of a domed steel head with a circular cast-iron flange having clearance inside the pipe. The outside of the flange is finished smooth and beveled to fit a solid circular rubber gasket which abuts against an inside circular flange of heavy angle iron, bolted through the rivet holes in the end of the pipe. The domed head is pin-connected at the center to a horizontal screw rod with a nut bearing on a transverse straining beam, by which the bulkhead is pulled tightly to place and leakage is prevented while the pipe is being filled with water; afterwards the internal pressure keeps the joint tight and the screw is removed.

At the Lyndhurst, N. J., crossing of the Passaic River, there is about 450 feet of pipe submerged to a maximum depth of about 15 feet which will be laid like that across the Hackensack river, but entirely different methods were employed for the two submerged pipe crossings near Boonton. Temporary dams were built across the Rockaway River above and below the pipe line and the river was carried between them in a wooden flume 12 feet wide, 4 feet deep and 30 feet long about on the center line of the old channel. The flume was caulked and floated into place in 3 feet of water and sunk on sills, after which the water was drained out from between the dams, a trench 11 feet deep dug across the 80-foot channel and under the flume. Then the pipe was laid and back filled, and the dams and flume removed.



Handling Pipe Section and Concrete Sleeve.

At the Passaic River crossing the topography favored the construction of a canal to by-pass the flow of the river around the dams, and where this canal intersected the pipe line the water was carried over the latter in a short length of flume so as to allow the pipe to be laid continuously, without waiting to return the river to its original channel. Here the river channel was 80 feet wide and 4 feet deep. At both crossings the bottom was of hard sand or gravel. The diversion dams were made with a puddle bank laid against a tight plank apron inclined about 30 degrees to the horizontal and supported on triangular timber frames about 10 feet apart. They were built with 2-inch planks and 8x8-inch timbers and had horizontal wheeling platforms on top from which the puddle was dumped in place.

The work is being built for the Jersey City Water Supply Company, Mr. W. B. Fuller, resident engineer in direct charge of all construction work, Mr. J. H. Gregory, division engineer in charge of all conduit lines, Mr. J. W. Smith, consulting engineer, and Mr. E. W. Harrison, chief engineer of the Jersey City Water Supply Company. The pipe is built, laid and tested under the supervision of the engineer corps and some of its special features were devised by Messrs. Smith, Fuller and Gregory, to whose efforts and ability as well as to the skill and experience of the contractors credit is due for the satisfactory execution of the difficult work involved in the construction at Hackensack River crossing of one of the largest and deepest of submerged pipes. The pipe is built and laid by the T. A. Gillespie Company, which has a plant at Paterson, N. J., for making riveted pipe, and has built several of the largest steel pipe lines in this country, including nearly 60 miles for the East Jersey Water Company, and lines for Allegheny, Minneapolis and other cities.

Concrete-Steel Piles and Their Driving.

While the new method of reinforcing concrete by embedded steel in various shapes has rapidly gained favor among the engineers of the world, the main attention has been given to that application which promised to be the most fruitful, concrete beams reinforced by steel. Now that the advantages of the concrete-steel combination for sustaining loads by flexure have been definitely established, the attention of engineers has turned to concrete-steel in the form of long columns and piles. Concrete steel piers were used on the X-bridge at Mans, France, by its able chief engineer, Harel de la Noè, and concrete columns reinforced by steel in the form of wires and rods have heretofore been used for various purposes, but there now appears to be a tendency to give more room to the application of this form of post. The experiments conducted by the Austrian Society of Civil Engineers and Architects, described in The Engineering Record of November 23, 1901, proved the great value of properly reinforced concrete in compression.

In a recent paper before the Institution of Civil Engineers of England on "Construction in Concrete and Reinforced Concrete," Mr. C. F. Marsh says: "The fact that piles made of reinforced concrete stand driving proves that beams, etc., of these materials may be subjected to moving loads without damage." He further describes the piles used in the Hennebique system. The square piles of concrete have a rod of mild steel in each corner about one inch from the surface of the concrete; the rods are bent inwards at the bottom and embedded in the shoe, which is of the ordinary form, and are held in position by 3/16-inch wire distance pieces, which are bent to fit loosely around the rods. These are dropped down from the top as required, and the sets are placed about six inches apart. The piles are moulded in an upright position, supported in timber racks, and about 3 inches of concrete are allowed over the tops of the rods, although piles can be driven with the tops of the rods flush with, or even slightly above, the top of the concrete without shattering.

Piles can be made of any length, size or shape required, and should it be desired to add to the length, when the pile is driven, or to connect piles to columns, it is only necessary to break away the concrete for the required distance, insert additional bars, and mould to the required height. The piles are driven with an iron cap in which a bag of sawdust is placed. Piles constructed in this way, 14x14 inches in cross-section, have been driven by a 2-ton monkey with a drop of 6 feet, and have stood perfectly. The driving of 12x12-inch piles with a 3,000-pound monkey and a drop of 4 feet is quite usual. The piles can be driven with perfect safety 3 weeks after moulding in the summer, but it is better to leave them for a month or 6 weeks in the spring and autumn, and, if not required after that interval, they can be taken from the rack and stacked.

Groups of piles driven to carry columns have the concrete at the top of the piles broken away for the required distance after being driven to the necessary depth; the rods of the column are then placed so as to overlap the rods of the piles and the concreting of the column is commenced. Columns and other vertical members are formed in much the same manner as the piles, but are generally moulded in place; the wire or flat iron cross-pieces need not be so close together as in the piles, being usually about 15 inches apart. The rods of the columns terminate at the bottom just above a steel plate which is embedded in the upper part of the foundation block. These foundation blocks are also of concrete reinforced by steel.

In the "Zeitschrift des Oesterreichischen Ingenieure und Architecten Vereins" of November 7, Mr. F. von Emperger describes a special pile driver built for concrete piles and the driving of such piles for the pier foundation of a small bridge. The pier rests on 11 piles, which form one solid body with the pier proper. This was attained by breaking away the concrete on the top of the piles and embedding the extended reinforcing bars in the pier. The piles were 16x16 inches, and were made in one length 14 to 16 feet long while lying horizontally. The ground was about 6.5 feet swamp on coarse gravel. The driving weight was 8,800 pounds and through the soft material it caused a penetration of 8 to 12 inches under a fall of 20 inches. When the gravel was reached the fall was increased to 3.3 to 4.25 feet, and at the beginning the pile sank 2 inches, but finally was driven practically to refusal by 80 to 120 blows with a penetration of 5/16 to 0.4 inch. Computing the bearing power of the pile by the well-known Ritter formula, the resistance to further penetration is:

$$W = \frac{h}{e}\,\frac{Q^2}{Q+q} + Q + q, \text{ in which}$$

Q = Weight of hammer in pounds = 8,800
q = Weight of pile in pounds = 8,800
h = Height of fall in inches = 48
e = Last penetration in inches = 0.4

This gives for W, 546,000 pounds. The load allowed per pile is controlled by the character of the material and about 22 tons or 178 pounds per square inch has been adopted as the upper limit. The latter value offers considerably more than the usually required safety and with it an increased stability of the structure. To determine the resistance of the concrete against shock the work done by the falling weight, 48x8,800 = 422,400 inch pounds is computed and distributed over the cross-section of the pile, giving 1,650 inch pounds per square inch as the impact resistance of the concrete.

Inquiry made by Mr. von Emperger on the behavior of the above described concrete-steel piles from the ministry of Elsass-Lothringen resulted in an elaborate reply which concludes that only good workmanship will give good results. The shattering of the concrete by the blow was of no account. In the case of one pile only the concrete broke away at the top of the pile and even this is believed to be avoidable. Another bridge built on concrete-steel piles has been decided upon by the same administration.

Siberian Coal was produced in 1900 to the amount of 320,000 tons, according to a British contemporary. There are a number of very rich and extensive fields which are being developed with increasing rapidity. In the Government of Tomsk there is a coalfield 270 miles long and 70 miles wide which contains seams of great thickness. In central southern Siberia there are five valuable deposits of coal and further eastward, in the Government of Irkutsk, there is a coalfield which produced 80,000 tons in 1900. A large supply of coal, accessibly situated, is of the utmost importance to the great railway lines recently built and now in progress.

Rail Tracks for Highway Traffic.

For some time past attention has been directed to the development of a suitable wheel track, especially for the use of heavily loaded wagons, which could be laid in streets and roads. The desirability of such a smooth track for wheels is evidenced by the persistency with which teamsters make use of street car tracks. Such a track should be of a gauge and width to accommodate a variety of vehicles, and the rails should be of such form as to facilitate turning into or out of the track and should not be dangerously slippery for horses' feet.

In a recent issue of the "Organ für die Fortschritte des Eisenbahnwesens" Herr A. Nessenius publishes an extensive study of the efforts and experiences of German engineers in the construction of an economical and serviceable iron track for highway purposes, which is abstracted below. The importance of this subject is well known and the discussion of the desirability and construction of iron tracks on highways has also been taken up among American engineers.

The first practical attempt to lay iron tracks on a highway was made in Germany in the year 1894, in the Province of Hannover, by the engineer Gravenhorst, where some 1,600 feet of iron track were laid as an experimental section. This first attempt was made with a cheap flat rail weighing 6.7 pounds per linear foot. The rails were in 33-foot lengths and their joints were made on cast-iron seats, which also secured the position of the track. There were no cross-ties nor any cross connections between the rails, which were supported on a layer of cement mortar laid on a continuous solid concrete foundation. The rail was depressed about 0.1 inch and longitudinal depressions were intended to provide a foothold for the horses. The width of this rail was about 5 inches.

While even this cheap and simple track proved to be in favor with most drivers, especially for the heavier traffic, it appeared very soon that it was not sufficient to offer a smooth rail for vehicles, but a more reliable guide must be provided to keep poorly horsed, carelessly driven and badly maintained vehicles on the track. It also proved to be wrong to depress the rails in the pavement, as was done in the trial section. The rough edges of the projecting stones were not sufficient to form a guide but caused shocks to the vehicles and rapid abrasion of the paint of the wheel-rims. It became further apparent that it was not sufficient to secure the flat rails at their joints to the concrete stringer which served as their foundation. When the sun heated the track, the loosely lying rails became wavy and began to rattle, while in rainy weather water and mud collected under them and spattered all around. An attempt was made to secure the flat rail to the concrete foundation by short pieces of Z-bars, but it proved to be a failure.

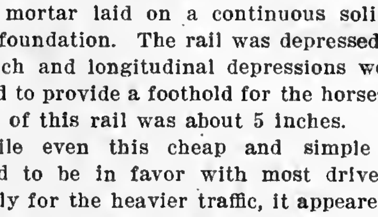


Fig. 1

A second trial with the section, shown in Figure 1, was successful. The flat rail is stiffened by two continuous Z-bars bolted to it from underneath, the space between them is filled with concrete and to prevent the separation of the filling from the rail a thin sheet of iron is bolted to the under side.

In the meantime, in another district a trial section was laid with an experimental rail similar to the street railway T-rail. After several experiments the section shown in Figure 2 proved to be serviceable and was adopted. Some difficulties were at first experienced in rolling this section, but they were soon overcome. The rail is now rolled the same as an I-beam section and the guide is bent up in passing the finishing rolls. These rails are manufactured in lengths of from 30 to 40 feet and weigh about

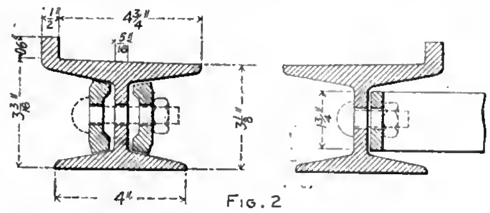

Fig. 2

50 pounds per yard. No difficulty is experienced in bending them to the required curvatures. The joints are made, as shown in Figure 2, the same as in railroad track. The rails are connected crosswise by light bars 1¾ inches by about ⅜ inch, and the weight of the completed track is 36 pounds per running foot. The rails must be laid with both guiding ribs on the inside, so that they will be between the wheels of the vehicles and thus provide secure guidance.

This arrangement makes the leaving of the track easier than when the guides are laid outside, since if a wagon has to leave the track and the horses draw in an oblique direction the externally running wheel is lifted up as with a lever. The drainage of the rainwater also offers no difficulty with this arrangement, while it would stay between the rails if the projecting guides were placed outside. In the Gardelegen district the gauge of track has been made 4.4 feet to centers of rails or 4.1 feet between guides. This makes the least width between wheels of vehicles using the track 4.1 feet.

With the adoption of the section shown in Figure 2 with its width or rolling surface of 4¾ inches in height of guide 0.6 inch, the correct form of the head of the rail seemed to have been found. The new track proved to be so successful that it was immediately laid on several long stretches of road. The guiding offered by the track is so secure that no special attention of the driver is required. Thus, for instance, a hunting party of the Imperial court, with about twenty wagons, drove a long distance over the track at night at the fastest trot, without any difficulty whatever. Three wagons coupled together always remain on the track notwithstanding sharp curves. It should be pointed out, what can be seen everywhere, that the horses begin to run faster as soon as the wagon gets on the track, due to the considerably reduced traction resistance. Vehicles passing across the track are not much annoyed by the projecting guides.

The favorable results which were obtained with the above described tracks induced the Province of Hannover to utilize them, but the box section first used was continued. This was done because the stresses in the different parts of the section are better distributed in the box section than in the T-section and thinner metal may therefore be used. When a crossing vehicle hits the guiding rib bending moments of considerable amount are caused in the T-rail section; this cannot occur in the box section where the bending moments must be very small on account of the direct support of the guiding rib. The greatest bending moment takes place in the box section in the upper level portion when a heavily-loaded narrow wheel runs in the middle; but even if the solid filling is neglected, the computed stresses are comparatively small. Still less are the stresses due to heavy vehicles with wide rims. It was further taken into consideration that the wide bearing area of the box rail will be less pressed into the soil than the comparatively narrow foot of the T-rail.

As a result of the above considerations Gravenhorst developed a rail section shown in Figure 3. It weighs 34 pounds per yard without appurtenances. Cross-connections are not provided. The hollow space is carefully filled with bricks or with concrete so that the rail bears with its full width on the foundation and

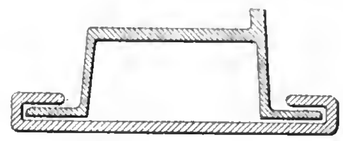

Fig. 3

the bearing area is thus made as large as possible. The sheet-iron bottom shown in Figure 1 is omitted, because the filling, consisting either of bricks grouted with a thin cement mortar and leveled up with a stiffer mortar, or of concrete, adheres firmly to the iron so that the rail can be overturned after 36 to 48 hours without loosening the filling.

The apprehension that the filling would gradually loosen under the effect of the vibrations and the unavoidable changes of temperature of the rails has not been realized so far; but even if a loosening should take place little harm would result, as the rails are secured to the foundation and the filling cannot drop out. The total width of this rail is 8⅝ inches and the rolling area is 4.8 inches; the guiding rib is 0.6 of an inch high and for ease in rolling and reduction of friction on the wheels the ribs have a 10 per cent. bevel. Trouble was at first experienced with the joining of this box rail, but finally the splice shown in Figure 3 was adopted. The box-rails are supported for their whole length by the foundation and secured by the pavement against displacement sidewise. No such displacement can be observed even at the ends of the track. The splices are, therefore, not stressed so severely as in railroad tracks. They have little to hold and thin iron wedges are sufficient to keep the rails in place. At the same time the rail can be straightened and the ends properly aligned.

The connection between the street pavement and the railroad track of street railways is generally one of the principal difficulties encountered in paving streets. The wagons using the track strike every time they get off the track against the adjacent pavement and once a slight depression is formed the wheels are easily guided along the rail and always hit the same spots of the pavement. The latter is thus comparatively easily depressed and is soon destroyed. The same difficulty is experienced with the above described tracks, but not in so high a degree, since the vehicles are securely guided by the track and commonly leave it only when passing each other or turning into another road. It should also be considered that the traffic on highways is much smaller than on city streets having railroad tracks. For cobble stone pavement, all that is necessary is to select the deeper stones and put them near the projecting rib and the shallower stones near the external edge of the rail. If the rails are deeper than the stones, they can be let into the foundation for the required amount or shallower rails used. With the box-rail the cobble stones lean against the walls and rest on the lower flanges. The level of the track is secured by the solid foundation which is required for this kind of pavement; the only precaution to be taken is that the sand cushion should be made sufficiently thin.

Should it be desired to lay the track on macadam roads having a foundation, the same would also prove sufficient for the rails; but the joint between the broken stone surface and the rails is so difficult to make, so unenduring and so troublesome in maintenance that the laying of tracks on such roads cannot be recommended. Even if the stones immediately adjacent to the rails could resist the wheel pressure of the vehicles hitting them accidentally, it could not resist the constantly recurring attacks of the horses. Recently the experiment of paving for a short distance the space between and adjacent to the rails with broken stones has been repeated; but has failed, as have all similar experiments.

For first-class pavements of large blocks or bricks, the foundation must be designed in each case. A good method is to fill the space in the rail section with tamped gravel. If conditions are favorable, the track will prove satisfactory even if laid on sand, but in most cases tracks laid on sand without foundation were soon distorted. Where gravel is not abundant and where good coarse sand which could be mixed with some cement is also scarce the rails may be laid on a layer of bricks.

To obtain a satisfactory joint between the rail and the pavement a new rail section has been invented which is shown in Figure 4. It weighs 12 pounds per linear foot. The rails are pushed in from both sides in the splice shown in the section, and are secured with thin metal wedges. Holes are bored in the rails, in which end pieces of the splices are bent over for further security. The lower ends of the sides of

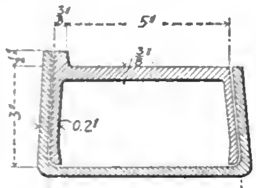

Fig. 4

the rails are somewhat bent in while passing the finishing roll to prevent the concrete filling from falling out should it get loose. For better drainage the surface of the rail has a slight inclination outwards. This is hardly necessary since the rails show a tendency to bend slightly outwards; for when a vehicle, with wheels further apart than required by the gauge of the track, passes over the rails, one pair of wheels will, as a rule, be near one guiding rib and the other pair will bear fully on the outer edge of the other rail; furthermore, the inner edges of the rails will usually bear the wheel load only when the vehicle goes on or off the track; and the T-rail would tend to overturn because of its narrow foot if the cross-ties did not prevent, but even with cross-ties a slight, though harmless, rotation of the rails takes place. Observations made recently by Gravenhorst at twenty points have shown an angle of inclination of 4 degrees 45 minutes in the average; but it should be remarked that no observations were made immediately after the track was laid and that it is therefore impossible to tell how much of the inclination was there initially and how much of it is due to later rotation. On good foundations the rotation of the box sections has been the smaller, notwithstanding the fact that there are no cross connections at all. Soon after the track is laid a slight side inclination can be noticed, but it does not seem to increase after the foundation has had time to settle.

There has been little experience to determine the allowable grades on the above described tracks. In 1900 a mile and a quarter was built with long grades varying from 2.5 per cent. to 3.8 per cent., with many curves, which proved to be fully satisfactory. Older roads having similar grades have also shown no disadvantages. Curves offer no difficulties and the rails are easily bent in the shop.

The question of the proper width of rail which was assumed 4¾ inches is a very important one. Supposing that the gauge adopted will suit most vehicles and that there will be a tendency to set the wheels to the adopted gauge, there will always remain a sufficiently great number of vehicles which will exceed somewhat the gauge so that their wheels on one side will run outside the rail, on the pavement. Experience affirms it by pointing to the ruts which are formed in the pavement alongside the rails, the width of these ruts varying from 3 to 4 inches, and evidently demands an increased width of running surface. Such a widened rail of a section similar to the one shown in Figure 3 but heavier has been laid on the busy highway between Mainz and Wiesbaden. Its rolling width is about 6 inches and it weighs 54 pounds per yard, but even this rail has not proved to be sufficiently wide. For a recently planned road, a new box section has been rolled which has a rolling width of 7 inches and a depth of 3⅛ inches.

The requirements for the guiding rib are to prevent involuntary derailment and to offer the least resistance to a wagon leaving the track, which are at once seen to conflict. The importance of this difficulty becomes more evident if it is remembered that, for reasons of economy, by far the greater number of highways have only a single track. Every meeting of two vehicles necessitates leaving the track. It was stated above that a ⅝-inch projecting rib kept the vehicles on the track, but it makes too difficult the leaving the track, and breaks of wheels have repeatedly happened. Whether the breaks were due to the bad condition of the wheels, careless driving, narrowness of road and sharp curvature, or to the rib, is not easily determined, but it cannot be disputed that the rims of the wheels are pressed with great force against the guide while turning off the track and that stresses are caused which the wheels were not designed to resist. A tendency to reduce the height of the projecting rib has therefore manifested itself. Experiments on some 120 feet of trial rails having ribs ½ to ⅜ inch high have been made and no objections have developed. An attempt to cut down the rib for a certain length in each rail to ¼ inch has failed, as the drivers pay no attention to these depressed sections.

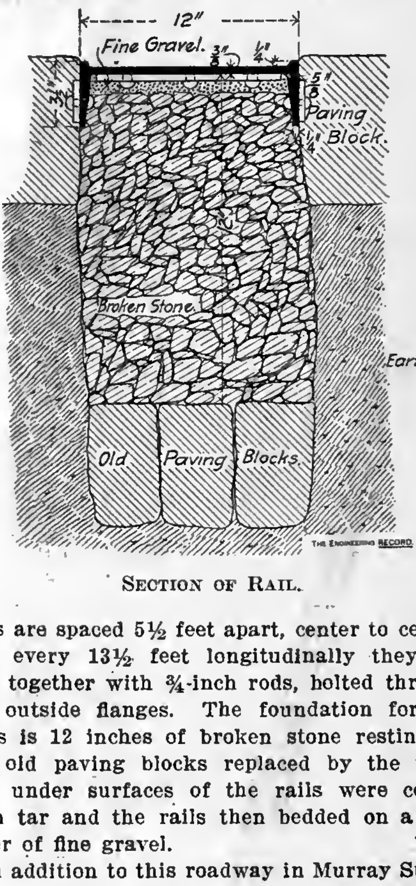
Measurements taken recently by Gravenhorst, and experience on the tracks, laid both with box section and T sections, seem to indicate that the best inclination to be given to the inside face of the guide rib is about 25 per cent., which is the inclination to which the ribs show a tendency to wear. The wear will then not be on the upper edge only but quite uniformly over the whole face and will be reduced in amount.

To the end of 1901 there were laid in Germany some 42½ miles of T-rail track and about 10 miles of box-rail track. From observations it has been found that a horse will move with the same effort a load three to five times as great on an iron track as on a stone pavement. The great favor which the iron tracks, where laid for long distances, enjoy among drivers is therefore understood. As to the effect of the use of iron tracks on the cost of maintenance of the highways, no data are available at present, since such information can only be obtained by many years of experience; but it is quite certain that the pavement near the track is used remarkably little, serving only for occasional turnouts. This will reduce the cost of repairs and maintenance in a considerable degree. Against this reduction the cost of repairs and the first cost and interest of the track must be charged.

A Steel Roadway in New York.

An experimental steel highway has recently been laid on Murray Street, between Broadway and Church Street, New York. The Automobile Club of America has been instrumental in securing this trial, and President Charles M. Schwab, of the United States Steel Corporation, furnished the steel at his own expense. Gen. Roy Stone, formerly head of the Bureau of Road Inquiry, Department of Agriculture, has charge of the experiment.

At present there is only a single roadway up the center of the street, on which loaded teams coming from the North River piers are given the right of way. The accompanying sketch shows a section through one of the rails, the depth of foundation shown, however, being somewhat greater than that finally adopted. The rail section is very similar to that of a 12-inch channel, the main difference being that there are slight ridges along the outside edges of the wearing surface, which tend to keep the wagon wheels in the track. The rails came in 40-foot lengths and were riveted together by means of three splice plates, one on the under side of the main web of the channel, having three rivets for each rail, countersunk on the top surface. The other two plates connect the flanges, each with two rivets to a flange. The



Section of Rail.

rails are spaced 5½ feet apart, center to center, and every 13½ feet longitudinally they are tied together with ¾-inch rods, bolted through the outside flanges. The foundation for the rails is 12 inches of broken stone resting on the old paving blocks replaced by the rails. The under surfaces of the rails were coated with tar and the rails then bedded on a thin layer of fine gravel.

In addition to this roadway in Murray Street, which will be subjected to the heaviest kind of traffic, it is proposed to lay another stretch of the steel road on Seventh Avenue in the neighborhood of 120th Street. Here the pavement is an old macadam, and there will necessarily be modifications of the foundation and the methods of construction to suit the locality. A trial will also be made on some dirt road, for the advantages of the steel rail are considered to be as great for a country road as for city streets.

At the present price of steel it is stated that the rails can be furnished for $4,000 per mile. The cost of construction would of course vary with local conditions, and as the work so far done is experimental and workmen had to be taught how best to perform the various operations of laying the track, no reliable estimate has been made as to the total cost of laying this roadway.

A thorough series of traction tests are to be carried on in connection with the roadway in Murray Street, and the other places where the rails are laid. A dynamometer will be used and the tractive force necessary to draw a truck over the granite paving will be compared with that necessary to draw it along the steel roadway. In addition to this test, records have been made showing the amount and weight of traffic on the street previous to the improvement, and further observations will be taken from time to time to see whether there is any increase in the traffic passing up this street.

Gen. Stone has made a very exhaustive study of steel highways, and has had several patents issued to him in regard to constructive details. These he states are to be entirely free to the city of New York to make use of, should the experiments prove as successful as is hoped. In rolling rails for further experiments it is proposed to make use of a special roll having slight projections on its surface, perhaps an inch square. The last time the rail goes through the rolls this will be put on and will leave corresponding depressions in the finished rail. The object of this is to reduce to a minimum the danger from horses slipping, and is an important consideration. However, it is claimed that the use of the steel rails will so reduce the amount of tractive force required that under ordinary conditions there will not be much danger from that source. Another proposed modification is to have the bead along the outer edges of the tread fluted so as to prevent wheels from skidding as they leave the track. In some cases it might also be advantageous to have the flanges of the rail flaring outward from the web on both sides, thus presenting a wider base.

There have been a few experiments on a small scale in this country with steel trackways, conducted by the Bureau of Road Inquiry, but lack of means to procure the desired shape of rail has hampered the Bureau in its investigations. One of these trials was with an 8-inch trackway on a gravel foundation, the weight of steel being about 100 tons per mile of single track road, furnished at $35 per ton. The most extended use of steel rails for roadways for which data is available, is in Spain on the road between Valencia and Grao, where about two miles of flint stone roadway was replaced by steel rails some ten years ago at a total cost of $9,500. The surface of the rails was placed somewhat lower than the paved road at the sides. The cost of maintenance of this road, over which a traffic of 3,200 vehicles passed daily, was at once greatly reduced, and the result was considered satisfactory in other ways. It seems probable that such a roadway as this would be greatly appreciated by market gardeners in the vicinity of large cities.

The Degree of Doctor of Engineering (Eng. D.) is to be conferred by the Massachusetts Institute of Technology, Boston, upon students in a graduate school of engineering research which is to be opened October 7, 1903. Students of marked ability who have received a degree of Bachelor of Science or have done work equivalent thereto, will be admitted to the school upon proper application and acceptance. Facilities will be afforded for advanced studies in civil, sanitary, mechanical, marine, mining and chemical engineering, applied mechanics, naval architecture, metallurgy and industrial chemistry. Six fellowships of $500 will be open to competition at the opening of the year 1903-04. The degree will be conferred upon candidates from the graduate school who shall have given not less than two consecutive years to special work, after presentation of a written dissertation on a subject previously elected, and examinations by the faculty of the Institute.

The Removal of Snow in New York City.

The form of contract for the removal of snow and ice in the Borough of Manhattan, New York City, this winter differs greatly from any previous contract given in that city. The chief difference is in the method of measurement. The amount of snow to be removed by the contractor and to be paid for by the city is to be determined by multiplying the depth of snow in the city as officially determined by the United States Weather Bureau by the superficial area of snow actually removed; this area to be ascertained from the area of streets as given in a set of maps prepared for this purpose.

Among the advantages of this system over that which has been followed during the past seven winters are, first, the city will have to pay only for work actually done, and not as before for imaginary cart loads corruptly or mistakenly checked off under the complicated system of measuring by cart loads previously pursued; second, the great temptation to dishonesty among the employes of the street cleaning department and others, afforded by the previous system will be avoided; third, under this system the members of the department of street cleaning, in place of being required, as under the previous system, to do a large part of the work for which the contractor was paid, will be employed wholly in the proper work of the department, as in cleaning crosswalks and the like.

It will be seen at once that the number of cubic yards measured by the recorded snowfall and the actual area cleaned will be considerably more than the amount as measured by the cart load. This shrinkage has been estimated at from 50 to 60 per cent.

Last winter under the old system there were removed 1,255,500 cubic yards at a contract price of 36¾ cents per yard, giving a total of something over $420,000. Adding to this amount the estimated value of the work done by the department in the way of furnishing officers and in many cases performing the actual work, the total cost is brought up to $570,000. This winter the contractor is required to furnish all the officers and do the entire work, the only cost devolving on the city being the salaries of eleven inspectors, one for each snow district. Thus the price bid by the contractor this year includes the $150,000 worth of work that the city performed under the old arrangement. At the contract price for this year, 25 cents per cubic yard, it would require the removal of 2,280,000 cubic yards measured on the new basis to bring the total cost up to $570,000. For the 30.36 inches of snowfall during last winter, this would mean about 75,000 cubic yards removed for each inch of snowfall.

There are 155 miles of streets in Manhattan to be cleaned, or over 6,000,000 square yards of surface, and it has been found that for every inch of snowfall there will be 170,000 cubic yards of snow on the complete schedule to be removed. In some cases, however, part of this will have been reduced to 4 inches or less in depth before the last part of the schedule is reached, and will not have to be removed; and as what is not removed is not paid for by the city, the actual amount paid for will in many cases be less than 170,000 cubic yards per inch of snowfall. Moreover when the snowfall is less than 4 inches it is optional with the commissioner whether or not any at all shall be removed. The average snowfall for the past 18 years is 35.27 inches, the smallest was 8 inches in 1900-1 and the largest 77 inches in 1892-3. On the snow maps the streets in which the different gangs will work are distinguished by different colors, and the area of each block, exclusive of intersections is printed on the map. The areas of the intersections are also printed in their respective places. No block will be paid for until it is completely cleaned.

It is interesting to note that under the new system it makes no difference to the city whether streets outside the schedule are cleaned or not, for the contractor can get no pay for such work. Neither does the city care how many times the same load is counted when the snow is being carted away, for that loss will also fall directly on the contractor. All the complicated system of inspection and oversight on the part of the street cleaning department is therefore done away with. In this connection it should be noted that much of the work of snow removal done by the department under the old form of contract was done at the expense of the removal of garbage and ashes, so that the accompanying inconvenience to householders will not occur this year. It may be stated that the contractor to whom the award has been recommended is in a position to do the work as cheaply and efficiently as possible. He is one of the large contractors on the subway, and therefore has a large and fully organized force at his disposal, which at the time of a heavy snow storm could not very well be employed on the subway.

This new manner of measuring the snow has been used in Europe to some extent, and the results of the present trial will without doubt be of much interest to municipal officers throughout this country. Mr. John McG. Woodbury is the present commissioner of the street cleaning department, and Mr. M. D. Bouton, who has advocated the new plan from the start, is the superintendent of the snow office. A few extracts from the contract as published in "The City Record" follow:

The Borough of Manhattan is divided into eleven districts, maps of which are submitted, as well as schedules showing the streets and portions of streets to be cleaned of snow and ice, and the order in which the cleaning is to be done. These maps and schedules herewith submitted form part of the contract. The contractor will have employed and working at least twenty vehicles and drivers and fifty laborers, exclusive of officers, in every gang on the subdivision specified in the schedules, within a period of three hours after the work shall be ordered. Such gangs to be kept continuously employed day and night, until stopped by the commissioner, with whom it shall be discretionary to order additional gangs at any time or at any point that may seem to him necessary.

The contractor shall remove the snow and ice from the streets and avenues hereinbefore specified, and from such other streets or portions thereof as may be designated by commissioner, and also from such portions of the sidewalks designated.

The contractor will secure the use of all necessary dumps and dumping places and will keep the water in and about the slips, piers and bulkheads clear from the snow and ice dumped therein, and the commissioner is to co-operate with the contractor in securing said dumps.

The contractor will furnish a sufficient amount and number of officers, laborers, materials, machines, etc., necessary to prosecute the work with all possible care, efficiency and speed. The contractor will go back over the work, if directed to do so by the commissioner, and will perform as many additional cleanings as the commissioner shall deem necessary.

The contractor will begin all the work at points designated on schedules and follow the schedules day and night without deviation, except by order of the commissioner or snow inspector. The contractor will on scheduled streets cause the snow and ice to be piled at least one long block or three short blocks ahead of each and every gang of vehicles or any division thereof.

The contractor shall promptly pay all laborers and other persons employed by him, and shall provide and keep on hand necessary funds and facilities for such payments and shall make such payments at least once in each week.

If the commissioner shall deem it necessary to use the regular force of the department of street cleaning, or any part thereof, or any other persons, materials, etc., for the removal of snow and ice, or, if surface or other railroad companies shall clean the snow and ice between their tracks in conformity with any law or ordinance, or from the entire width of any street or streets with the consent of the commissioner, the contractor shall not in any way interfere with or molest such other force, persons, etc., and shall carry on the work on the remainder of the schedule, and shall not ask any compensation on account of the work so done by the department of street cleaning or other forces as aforesaid.

The contractor may use machines, appliances, etc., for melting the snow and ice, if approved by commissioner, such melting to be so carried on as not to unnecessarily impede or interrupt traffic.

The amount of work done by the contractor shall be ascertained as follows: The commissioner shall station in each district one or more special inspectors or district superintendents, whose duty it shall be to report in writing to the snow inspector the number of blocks of streets fully cleaned by the contractor during the previous twelve hours; and from these reports the snow inspector shall compute the number of cubic yards of actual snowfall removed by the contractor during the said twelve hours preceding. Only entirely completed blocks shall be considered, and no block only partially cleaned shall be considered in the amount of work for which the contractor shall be paid.

All computations of work done by contractor shall be made from measurements of the area of the department of street cleaning districts drawn from the original surveys made by the Sanborn Map Company for the department of street cleaning, a set of which is attached to contract. In all computations for payment, the cubic yards of actual snowfall shall be the basis of calculation, as determined by said maps.

The depth of the snow for any given snowfall shall be the depth as officially determined and reported by the United States Weather Bureau located in the city of New York; provided, however, that if the commissioner of street cleaning shall establish his own method and appliance for measuring the depth of the snow, then the depth so measured and determined shall be the depth made use of under the contract.

When, from weather or other conditions, the snow and ice shall be reduced to an average depth of four inches or less, it shall be discretionary with the commissioner to suspend the work until the occurrence of another storm. The inspector shall, in all cases, determine the amount of work to be paid for under the contract.

The damages to be paid by the contractor for delay in beginning the work within the period of three hours is fixed at $25 for each and every hour of delay at each and every block. The damage to be paid by contractor in case the drivers or others dump on any public street or place not approved by the commissioner is fixed at five dollars for each and every load so improperly dumped.

The Earnings of the Steel and Iron concerns of the United States for the year 1902 are estimated at nearly $200,000,000.

New Books Received.

It is intended to publish under this heading, from time to time, brief mention of books recently received. These books will be reviewed and more extended notes relating to them printed at as early a date as practicable.

THE CIVIL ENGINEER'S POCKET-BOOK. By John C. Trautwine, C. E., revised by John C. Trautwine, Jr., and John C. Trautwine, 3d. New York: John Wiley & Sons. 16mo., 1,100 pages, illustrated, morocco. Price, $5.

ELEMENTARY APPLIED MECHANICS. By T. Alexander, C. E., M. Inst. C. E. I., professor of engineering, Trinity College, Dublin, and A. W. Thomson, D. Sc., professor of engineering, College of Science, Poona. New York: The Macmillan Company. 8vo., 575 pages, illustrated. Price $5.25, net.

THE RAILWAY CONTRACTORS' HAND BOOK, containing tables of level cuttings or banks, for single or double track and for second track work, etc. By John M. Hazen, 501 New York Life Building, Minneapolis, Minn. 4½x6 inches, 147 pages. Published by the author at $2.

ANCIENT AND MODERN ENGINEERING AND THE ISTHMIAN CANAL. By William H. Burr, C. E., M. Am. Soc. C. E., M. Inst. C. E., professor of civil engineering in Columbia University. New York: John Wiley & Sons. 8 vo., 473 pages, illustrated. Price, $3.50 net.

A DISCUSSION OF COMPOSITION, especially applied to architecture. By John Vredenburgh Van Pelt, Architecte diplomé par le Gouvernement Français; professor in charge of the College of Architecture, Cornell University. New York: The Macmillan Company. 8vo., 275 pages, illustrated. Price, $2 net.

Book Notes.

Information relating to municipal affairs is so frequently presented in an uninteresting tabular form that one is sometimes apt to think that these subjects cannot be presented in such a way as to be attractive and interesting reading. In a book entitled "American Municipal Progress, Chapters of Municipal Sociology," Mr. Charles Zueblin, professor of sociology in the University of Chicago, has succeeded, however, in presenting many statistics and drawing a variety of interesting comparisons in a readable form. The tabular information is not interspersed in the reading pages, but is conveniently collected in appendices. The book treats of transportation, public works, sanitation, public schools, public libraries, public buildings, parks and boulevards, public recreation, and public control, ownership and operation, and is one of the series of the Citizens' Library of Economics, Politics and Sociology edited by Richard T. Ely, Ph.D., LL.D., and published by the Macmillan Company, New York, price $1.25 net. The book is provided with a good index.

In the 1901 revised edition of "Cooper's Specifications for Railroad Bridges," now so well known, the constant increase of weight of rolling stock of railroads has found its expression in the engine diagrams for live load, which now provide axle loadings up to 50,000 pounds and following uniform loads of 5,000 pounds per linear foot. Among new features exemplifying the onward march of the art of bridge construction it may be mentioned that no distinction is now made in the unit stress permissible in eye bars and on riveted tension members. All lateral sway and portal bracing must be made of shapes capable of resisting compression as well as tension and must have riveted connections, rods and bars being thus prohibited. Adjustable members generally are discountenanced, one stipulation being that adjustable counters be avoided where practicable. Floorbeams of through bridges are to be riveted to the posts above or below the pins. All bridges of over 80-foot span are to have hinged bolsters at both ends. For the first time in his general specifications Mr. Cooper specifies the process of manufacture for steel, the open hearth process being called for, and a limit has been placed on the percentage of phosphorus. The elastic limit has been given a specific definition, the so-called yield point being accepted only under clearly defined conditions. Sheared edges must be planed, but the requirements for reaming are less rigid than before. The greatly increased foreign trade of the United States in bridge work is covered in a paragraph on "Export Work," in which special conditions governing such work are given. In an appendix are added useful tables of moments and shears for different lengths of span, and a table of recent heavy passenger and freight engines. At the end of the specifications are some very pertinent remarks about the relative cost of bridges proportioned for the different classes of live load, the probable development of rolling loads of the future and recommendations for the use of the heavier classes of live load for all railroads with a future. Printed by the Engineering News Publishing Company.

Assistant Professor C. E. Coolidge, of Cornell, is the author of "A Manual of Drawing." This book is written principally for the use of students of mechanical drawing. It is designed to give them an understanding not only of the different instruments and materials used in the preparation of commercial mechanical drawings, but also a knowledge of what these drawings are and how they are to be prepared. The system of drafting room practice described is similar to that used in many of the leading commercial drafting-rooms. It is unfortunate that the illustrations in the back part of the book are not of better quality. The book is published by John Wiley & Sons, New York, at $1.00.

While prepared primarily for the use of beginners, a book of value to all persons interested in structural design is Professor Malverd A. Howe's "The Design of Simple Roof-Trusses in Wood and Steel." In addition to the collection of tables and other useful information concerning roofs, this book contains an introduction to graphical statics, a chapter on the strength of wood and steel, and designs for three roof-trusses of short spans. The chapter on framing of joints in wood is interesting and the details therein given can be applied to many forms of wooden structures. There is little that is new in the book, consequently its value lies in the fact that information, which has been heretofore more or less scattered, is now brought together and well arranged. It is published at $2.00 by John Wiley & Sons, New York.

A second edition of the "Diagram of Connections of the Series-Parallel Controller" has been published by Loxley Bros., Sheffield, Eng., price one shilling. This is a chart 13½x18¾ inches, designed by E. A. C. Kochs, engineer in charge, Corporation Tramways Power Station, Sheffield, and shows the various connections of a series-parallel controller for two motors and an electric brake. The diagram is clear and the path of the current can be easily traced for every position of the controller handle. The leads, connections and contacts are shown in colors, which facilitates the use of the chart. All the accompanying devices, such as switches, fuses, circuit breakers, lightning arresters, etc., are also shown properly connected in the wiring system. It is useful for reference to the engineer or electrical worker and equally intelligible to both, the explanatory text being clear and easily understood.

A book intended for use in the metallurgical laboratory of technical school, is "Metallurgical Laboratory Notes," by Henry M. Howe, professor of metallurgy in Columbia University, published by the Boston Testing Laboratories, at $2.50. The author's intention is to work out a system by which the student may become familiar, not so much "with the individual processes each as a whole, but with the individual underlying principles, each by itself," and to familiarize the student with such instruments of precision as those required in pyrometry, calorimetry, and the microscopy of metals and alloys. He has endeavored to make plain all the little details of the various experiments, so that the student may have nothing to distract his attention from the principle which the particular experiment is meant to show. The book is devoted entirely to experiments, beginning with those which would give a large class a smattering of metallurgical conditions, passing on to the examination of the principles of pyrometry and calorimetry and the instruments used therein, the melting points of various silicates and the determination of the relation between the formation point and the melting point, and finally taking up the principles of iron, steel and copper work, giving a fair proportion of attention to the microstructure of various steels and alloys. At the end of the book are given a few tables which are of value to the student undertaking the course.

On account of the present scarcity of books upon the subject, "Stereotomy," by Arthur W. French, professor of civil engineering, Worcester Polytechnic Institute, and Howard C. Ives, instructor in civil engineering in the same institute, just issued by John Wiley & Sons, will prove valuable to many. The book begins with a short description of building stones and the methods of quarrying, dressing and laying them, which is supplemented with a few general specifications for stone masonry. Attention is called to the manner of preparing and using the various bevels and rules needed by the stone cutter. The suggestions made and directions given to study stone work by means of models cast in plaster are useful and practical. A few neat methods of laying out the outlines of arches of various forms are given, together with a number of exercises in the application of descriptive geometry to stone plans, the value of which is chiefly theoretical. Interspersed with these, however, are examples of stone plans for buildings, piers and arches taken from actual practice. The authors properly recognize the increasing use of concrete in places where, a few years ago, cut stone would have been used, by devoting one plate to the working drawings for a concrete arch culvert. In a few places, references to the literature of the subject are given; a larger number of such references would add to the value of the book. The book is illustrated in the text, and has numerous plates. It is sold at $2.50.

The Sanitary Protection of the water supply for Brooklyn, N. Y., for the months of July, August and September is summarized as follows in the quarterly report of Commissioner Monroe: In connection with the patrolling of streams, ponds and wells throughout the watershed, 4,844 privy-closets and cess-pools, 2,327 of them in and about Hempstead, were cleaned. A new map giving the location and nature of all nuisances in the watershed has been prepared with the view of applying to the State Board of Health for more stringent regulations to suppress pollution of water needed for Brooklyn's supply.

Ventilation and Heating in a Philadelphia Department Store.

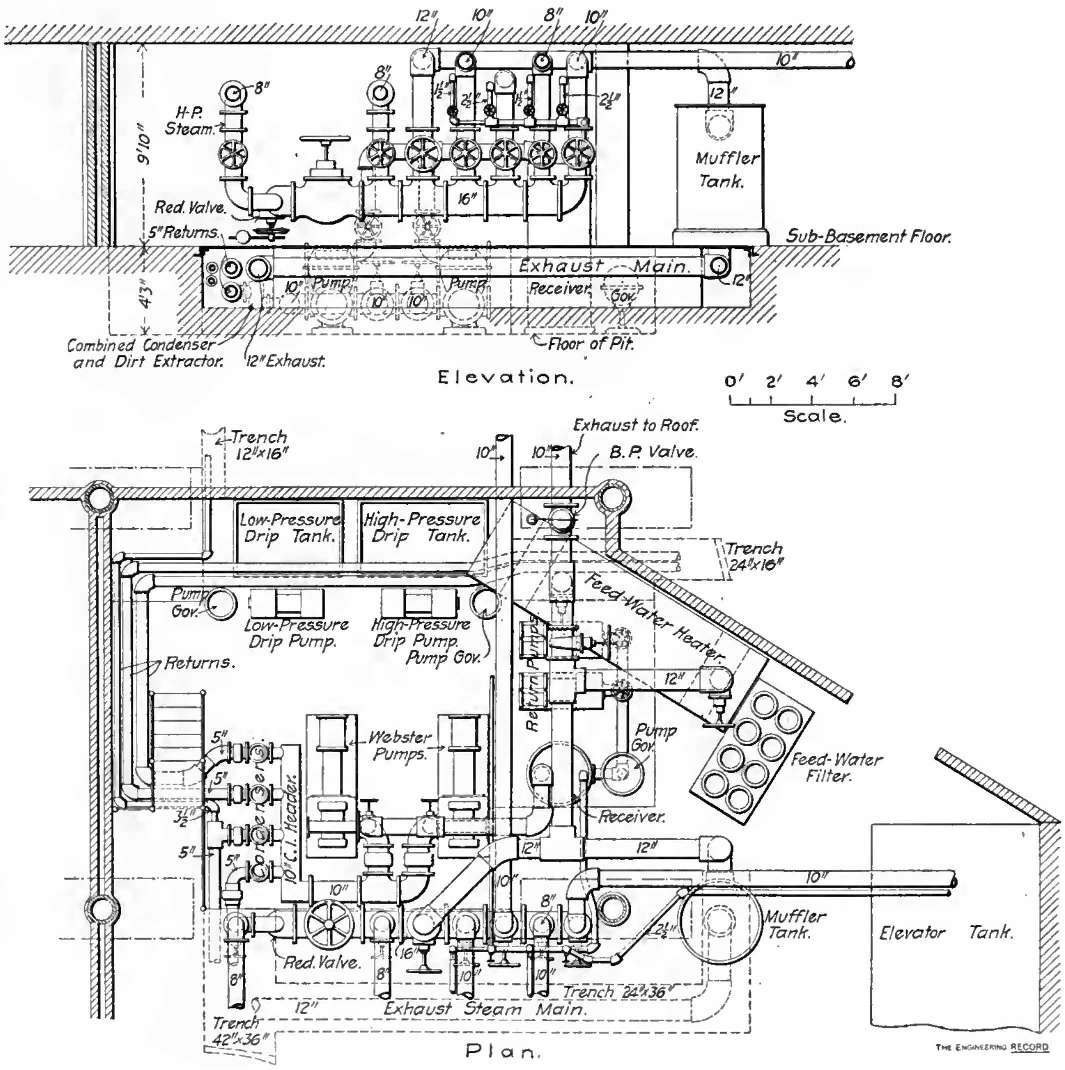
Messrs. Gimbel Brothers, of Philadelphia, have recently completed a large addition to their department store in that city, in which they have combined their mechanical apparatus in a single plant serving both the old and new structures. The design and performance of the new system of ventilating and heating furnishes a good example of a method of performing those operations in a large department store, where each floor consists practically of a single room, of large area as compared with its height. In the lower and most used floors, the combined plenum and exhaust system has been employed, hot air being delivered through generously distributed outlets. The total capacity of the exhaust system is slightly less than that of the plenum system, the purpose being to establish within the store a sufficient pressure to prevent an indraft of cold air every time a door is opened. Special attention has been paid to the warming of the entrance vestibules, no radiators being used, but hot air provided instead.

The building is located on Market Street, between Eighth and Ninth Streets. The new addition is on Eighth and Market Streets and about 300x135 feet in area, which makes the total ground area, now, 95,280 square feet. The main part of the old building and the addition are nine stories in height, with a small tenth story addition on the corner of Market and Ninth Streets, which contains a barber shop, manicure and dental parlors, and dressing and work rooms in connection with a photographic studio. The mechanical work brought about by the additions and changes included the complete erection of the steam power, heating and ventilating plants for the new building, the installation of a ventilating plant for the basement and sub-basement of the old building, of an indirect heating system for the old part of the first floor, the installation of the Webster system for the entire heating apparatus, and the re-arrangement and removal of piping, pumps, boilers, etc., where replaced by the new systems.

There were formerly two separate power plants in the building, but these have been removed and are now replaced by one new power plant. The boiler equipment consists of four Edge Moor steam boilers of 300 horse-power each, which generate steam at 110 pounds pressure. An outlet from each boiler is connected into the high-pressure steam main, dropping down to the sub-basement floor in the form of a drip leg 16 inches in diameter. From this leg, the main pipes are taken with branches to the blower engines, all pumps, the hot-water tank, the refrigerating machinery, the air compressors for the sewage ejectors, the steam injectors, the auxiliary live steam connection to the heating system and the kitchen and lunch room supply mains.

In the last named places, i. e., the lunch room in the sub-basement and the kitchen on the seventh floor, the steam is used for cooking purposes. It is supplied at 40 pounds pressure through reducing valves with the usual by-passes. The returns from the apparatus thus supplied connect to the high-pressure drip system. All sinks and plumbing fixtures likely to accumulate grease are also provided with live steam connections for blowing them out.

All individual branches to engines, pumps, etc., are taken from the top of the mains and have two valves, one near the main pipe and one at the pump or engine, as the case may be.



Distributing Center of the Heating System.

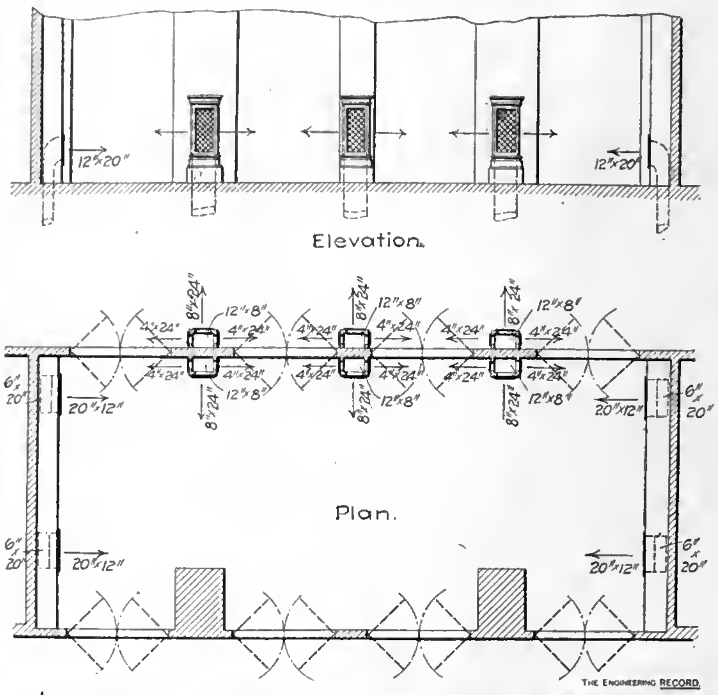
The branches to the elevator pumps, cash system blower engines and to the refrigerating machine are fitted with steam separators.

The drainage from all high-pressure lines is brought to a high-pressure drip tank which is 3 feet 6 inches in diameter by 6 feet long, and made of ⅝ inch charcoal hardened iron, with heads of ½ inch flange iron. It contains a cooling coil of 3 inch seamless brass pipe, containing 60 lineal feet, through which cold water is passed. A 3 inch vent from the tank allows the escape of entrained air and vapor. The tank is drained by a 6x4x6-inch duplex pump, controlled by an automatic governor, and discharges its contents to a 3½-inch main feed line, or may be by-passed to the cess-pool.

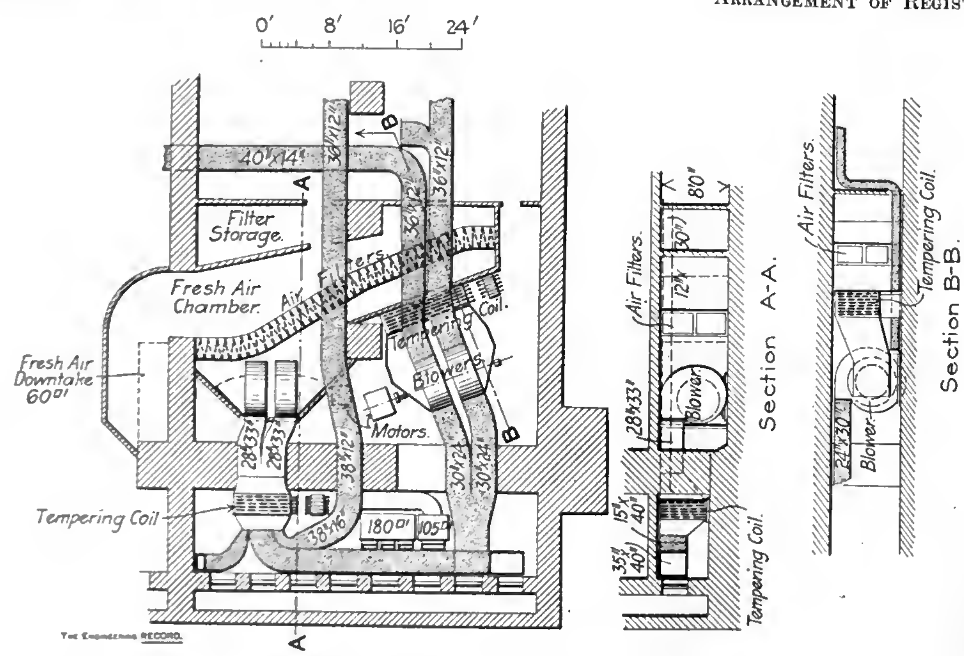
There are five engines in all, two driving the blowers for the cash-conveying system, and three upright engines are each direct-connected to blowers for the hot air heating of the main entrances. Altogether there are sixteen steam pumps. Besides the pump mentioned for draining the high-pressure drip tank, there is one of the same size for discharging the low-pressure drip tank. Three 7½x5x6-inch pumps drain the cess-pool and the blow-off tank and feed the boilers. The heating system is provided with two Webster vacuum pumps, 12x16x16 inches, with a special vacuum controlling valve connected to the return pipe of the heating system, and two return pumps, 7½x5x6 inches, for returning the water of condensation from the heating system and tempering coils to the main feed line. The feed, blow-off and cess-pool pumps, are cross-connected, and being of the same size, may be used interchangeably. The return pumps and the high and low pressure drip pumps are similarly cross-connected. The pumps used for hot water are brass-fitted throughout and built to stand a working pressure of 150 pounds.

The exhaust steam from the cash blower engines and all of the pumps, is collected by branches into a 12-inch exhaust main under the sub-basement floor, and conveyed to a Potter muffler tank. This tank is 4 feet in diameter and 6 feet long, made of the same material as the drip tanks, contains 24 galvanized screen disks, and is dripped to the low-pressure tank. Beyond the muffler, the exhaust main contains a Cochrane grease extractor and then branches, one part going to the 16-inch header from which the mains to the heating system and hot-water tank are taken, and one part to the feed-water heater.

A heavy pressure Berryman closed feed-water heater, 45x173 inches, of horizontal pattern, is used. It contains 300 square feet of heating surface consisting of 2-inch seamless drawn brass tubing. The shell is of steel, 7/16 inches thick with heads ½ inches thick and is supported by pipe columns. The heater has 3½-inch feed-water connections. The exhaust steam inlet and outlet are 12 inches in diameter, and there is a full-size bypass around the heater. Continuing from the heater, the exhaust passes through a back-pressure valve to the 10-inch exhaust riser to the roof. The top of the riser is fitted with an exhaust head of galvanized iron, which is dripped to the low-pressure drip tank.



ARRANGEMENT OF REGISTERS IN A TYPICAL ENTRANCE.



DETAIL OF THE 5 AND 5½-FOOT BLOWERS.

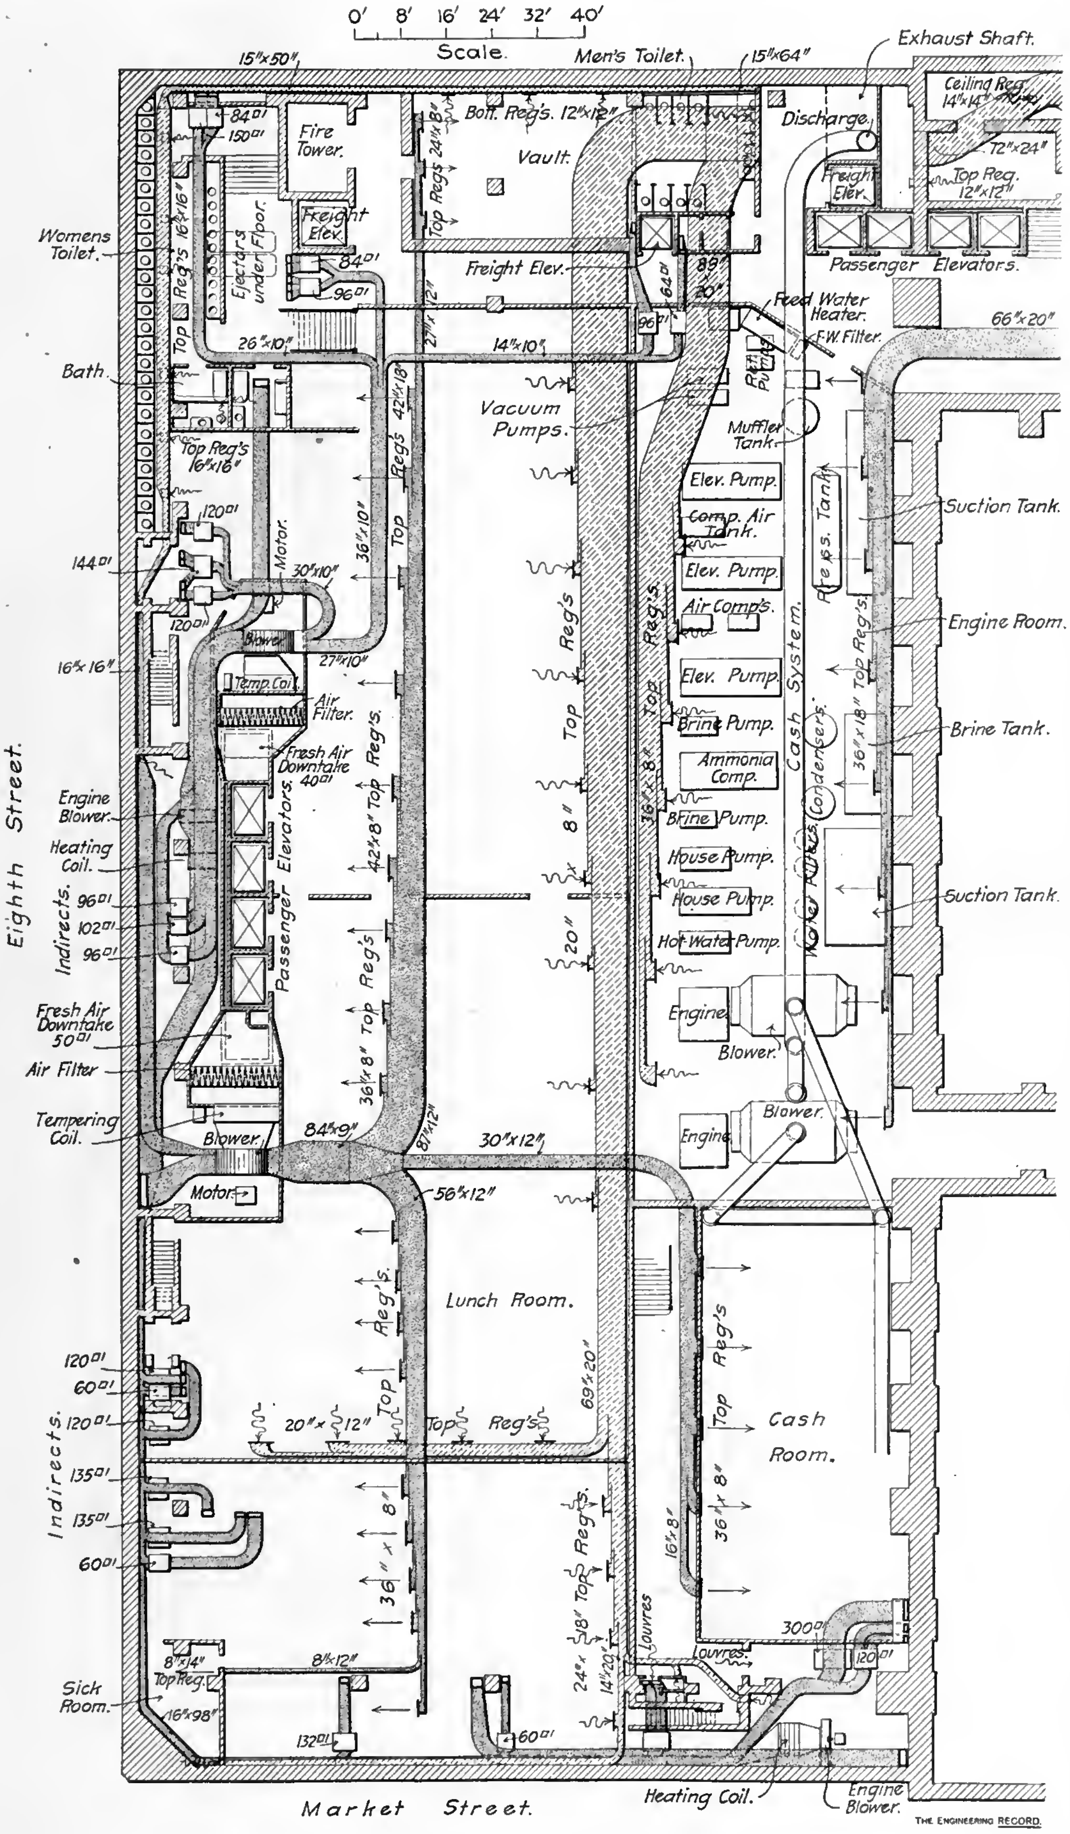
The low-pressure drip tank, which receives all oily drips, is one foot shorter than the high-pressure tank, but is otherwise its exact counterpart. It is drained by a pump, which is controlled by a Kieley automatic governor, and discharges its contents to the sewer. Three-inch vapor pipes from both drip tanks and the blow-off and receiving tanks, with a valve on each, connect to a 5-inch vapor riser to the roof, at which point there is an exhaust head of galvanized iron, similar to the exhaust steam head, and also dripped back to the low-pressure drip tank.

The 16-inch low-pressure header, from which four steam mains for heating purposes are taken, is supplied ordinarily by exhaust steam, but may also be fed with live steam through a reducing valve. One 10-inch main supplies the direct radiators, the indirect stacks for the first floor of the new building, and such low pressure steam as may be required by the fan systems for heating the entrances in the new part. Another 10-inch main supplies the corresponding apparatus in the old building. A third 10-inch and an 8-inch main supply the tempering coils of the ventilation blowers in the new and old buildings respectively.

Direct radiators are used entirely on all floors above the first. The first floor is heated by hot air in connection with the ventilation, the heating being done by indirect stacks located at the bases of flues from the main ventilating ducts in the basement. The indirect stacks are enclosed in casings of galvanized iron No. 20 gauge and stiffened with angle iron. The entire bottom of the casing is hinged to allow ready access to the heating surfaces. This hot-air system is assisted in a few places by direct radiators, and the basement also has a few. As the basement is not so exposed as to require much more heat than rises naturally from the sub-basement, its air supply is merely tempered.

The six main entrances are heated by hot air, through vertical registers set in the sides of cast-iron boxes. The register boxes rest on the floor and form caps to the flues opening under them. Some of the boxes are at the sides of the vestibule, and others are arranged in pairs between the doors of the partition which separates the vestibule from the inside of the store. The placing of the registers is shown on the accompanying detail of one of the Market Street entrances. As the large doors of the entrances are being continually opened, it is necessary to discharge a considerable quantity of air into the vestibules and under high pressure. The velocity through the registers is about 300 feet per minute.

In the proportioning and placing of radiators and indirect stacks, it was designed to warm all rooms in the old and new buildings to 70 degrees in zero weather with a pressure of steam in the heating main not to exceed 5 pounds. There are about 350 radiators throughout the entire building, ranging in size from 36 to 200 square feet of heating surface, the average being about 70 square feet. There are



Plan of the New Part of the Sub-Basement.

14 indirect stacks in as many hot air flues, with an average of about 50 square feet of heating surface in each. The total surface of all radiators is 26,346 square feet, of indirect stacks 699, making a total in both of 27,045 square feet. Adding to this the surface in the tempering and heating coils in connection with the blowers, which will be discussed in their proper place, the complete total of heating surface supplied is 35,745 square feet.

The returns from radiators and heating and tempering coils are brought back in mains under the floor of the sub-basement to combination dirt extractors and jet condensers, and are then collected in a cast-iron header from which the vacuum pumps remove the condensation and pass it to the receiving tank. The receiving tank is 36 inches in diameter and 8 feet long, of the same material as the drip tanks. Its contents are removed by the two return pumps, controlled by a Kieley governor, and delivered to the main feed line, or may be discharged to the cess-pool. The 3½-inch feed main is also supplied with the high-pressure drips. The water is discharged from this main through a filter and the feed-water heater in turn, after which it is delivered to the boilers by the feed pumps. The filter is of the Ward type, composed of 8 cast-iron cylinders, 15 inches in diameter by 7 feet 3 inches high, fitted with a complete set of special cast zinc bars and filled with animal charcoal. Ordinarily the loss of condensed steam through the low-pressure drips, which are wasted, and the loss of steam to the atmosphere, are compensated for in the make-up of boiler feed, by introducing cold water through a 1-inch pipe from the street service, into the high-pressure drip tank.

Blow-off pipes are run from each boiler connecting into a 3½-inch main line leading to the blow-off tank. The suction pipe from this tank is connected with the blow-off pump which discharges to the sewer. The blow-off tank is of the same size and construction as the receiving tank, and like the drip tanks, it contains a cooling coil of 3-inch brass pipe, in this case consisting of 80 lineal feet. The cess-pool is drained by the pump for that purpose, and is discharged into the sewer. It is fitted with a Worthington automatic regulator for controlling the water level in the cess-pool, and a foot valve with a removable strainer.

All steam pipes 4 inches in diamater and above, subjected to boiler pressure, are of extra heavy wrought-iron pipe with extra heavy flange unions and fittings, and the joints are packed with corrugated copper gaskets. All cold water pipes are of galvanized iron with galvanized fittings, and all other pipes are of standard wrought-iron with gray cast-iron screw fittings made up without packing of any kind. All boiler-feed pipes from the feed and return pumps and injectors are of iron-pipe-size hard-drawn brass with brass fittings. The feed-water heater, filter, muffler tank, grease extractor, blow-off, receiving and drip tanks, separators, pump governors, traps, fittings, valves and hot pipes are covered with 85 per cent. carbonate of magnesia covering of the Philip Carey Manufacturing Company's make.

The ventilation of the building combines the plenum and vacuum systems, as will be seen from the accompanying cuts. The basement and first floor are supplied with fresh air by five forced systems, established by seven Sturtevant centrifugal fans in the sub-basement, in connection with tempering coils to heat the fresh air to the proper degree in zero weather, and all floors are vented by two exhaust systems, an east and a west with two Blackman disk fans in houses on the roof.

One fan for the fresh air supply to the new part of the sub-basement and basement, has a blast wheel 9 feet in diameter by 4 feet 6 inches wide. There is a tempering coil in its discharge 10½x8 feet over all, having a heating surface of 2,300 square feet. The blower is driven at 150 revolutions by a 20-horse-power motor and has a capacity at that speed of 48,000 cubic feet per minute.

The old part of the sub-basement and basement is supplied by two blowers on the same shaft, and connected on one side to a 16-horse-power motor. Each wheel is 5½ feet in diameter and 2 feet 8 inches wide. They are driven at a speed of 240 revolutions per minute with a capacity of 17,000 cubic feet each, and their combined discharges are passed through a tempering coil, 10½x6 feet, containing 1,700 square feet of surface.

The first floor of the new building receives fresh air from a blower with an 8x4-foot wheel, direct-connected to a 12-horse-power motor and running at 150 revolutions per minute. It discharges through a tempering coil, 8½x7 feet in size, with 1,700 square feet of heating surface. The old part of the first floor is supplied by two connected fans on the same shaft with a 10-horse-power motor. The wheels are 5 feet in diameter and 2 feet 4 inches wide, run at 240 revolutions and discharge together 22,600 cubic feet of air per minute through a tempering coil with 1,200 square feet of surface and 6½x6 feet over all. The blowers take their cold air from fresh air shafts having inlet windows between the first and second stories.

The air for the engine and boiler rooms is taken from an in-take in the rear of the sub-basement and delivered untempered by a blower with a 6x3½-foot wheel, direct-connected to a 12-horse-power motor. It runs at 225 revolutions, discharging in one minute 23,300 cubic feet of air.

For the combined heating and ventilating of the three main entrances, there are three steam-driven fans in the sub-basement. These have blast-wheels 60x16, 54x14 and 48x12 inches, and are direct-driven, respectively, by 7x5, 6x5 and 5x4-inch double enclosed upright engines of the automatic cut-off type. The 5-foot blower runs at 475 revolutions and discharges 8,000 cubic feet of air per minute through a 5½x4-foot heating coil containing 800 square feet of surface. The 4½-foot blower runs at 500 revolutions and discharges 6,000 cubic feet per minute through a heater 5½x3 feet with a total surface of 600 square feet. The 4-foot blower discharges 4,000 cubic feet per minute, at 550 revolutions, through a 4½x3-foot heater with 400 square feet of heating surface.

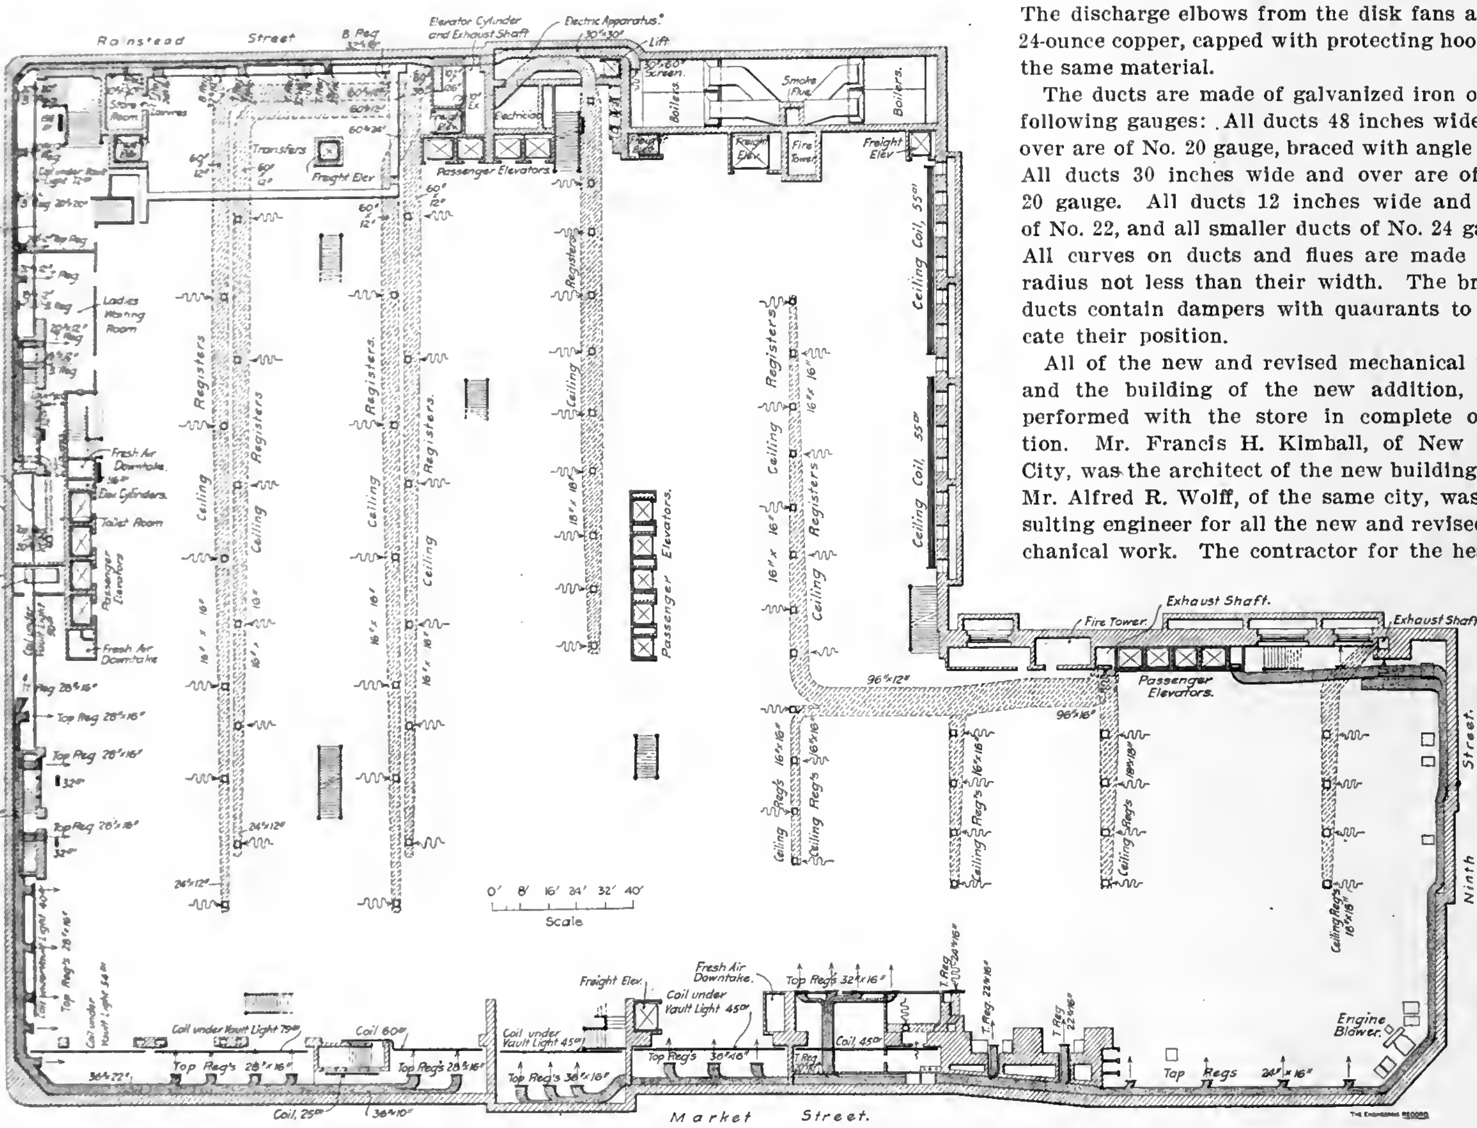
All blowers are encased in full steel plate housings and have wheels with curved blades. Where parts of fan housings extend below the floor level, such parts are built of steel ¼ inches thick, riveted, caulked and made water-tight. All fans have steel shafts of extra large diameter and are connected to their motors by flexible couplings. The tempering coils in connection with each motor-driven blower are divided into seven 2-row sections, making the coils 14 rows deep. The heating coils for steam fans are divided into one 2-row and four 4-row sections, making the coils 18 rows deep. The outside sections of the blower heaters are supplied by the exhaust of their respective blower engines, and return their condensation to the low-pressure drip system. Each section is controlled separately by hand valves on the supply side, and a thermostatic trap on the return. The sections are all made of 1-inch pipes screwed into separate cast-iron headers on steam and return ends, are encased in jackets of No. 12 steel plate, and are supported from the floor by a framework of I and channel beams. The blowers are of the B. F. Sturtevant Company's make and the motors are of the C. & C. type. The latter are equipped with controllers to give them three variations of speed ranging from two-thirds to the full speed as given before. Current for the motors is taken from the street supply.

Each fresh air inlet is provided with a brass wire screen of 3-inch mesh, and operating devices such as dampers, doors or pivoted louvres. The fresh air chambers contain air filters consisting of galvanized wire netting on wooden frames and covered with cheese cloth. The filter area from the 9-foot blower is 720 square feet, that for the 8-foot 860 square feet, and the two 5½ and two 5-foot blowers have a single filter with an area of 1,200 square feet. The frames are supported by galvanized iron, stiffened by T-iron and anchored to the floor and ceiling.

For the removal of foul air from the basement and sub-basement, ducts of large area and many openings are run on the ceilings. These lead to vent shafts rising beside two groups of passenger elevators. On the top floors these shafts are connected by ducts with all of the vent flues from the upper parts of both sections. The east section is exhausted by an 11-foot disk fan coupled to a 30-horse-power motor and running at 150 revolutions per minute, and the west section by a disk fan with a 7-foot wheel and coupled to a 15-horse-power motor running at 250 revolutions per minute. The larger fan has a capacity of 120,000 cubic feet per minute and the smaller one 40,000 cubic feet per minute. The discharge elbows from the disk fans are of 24-ounce copper, capped with protecting hoods of the same material.

The ducts are made of galvanized iron of the following gauges: All ducts 48 inches wide and over are of No. 20 gauge, braced with angle iron. All ducts 30 inches wide and over are of No. 20 gauge. All ducts 12 inches wide and over of No. 22, and all smaller ducts of No. 24 gauge. All curves on ducts and flues are made on a radius not less than their width. The branch ducts contain dampers with quadrants to indicate their position.

All of the new and revised mechanical work and the building of the new addition, were performed with the store in complete operation. Mr. Francis H. Kimball, of New York City, was the architect of the new building, and Mr. Alfred R. Wolff, of the same city, was consulting engineer for all the new and revised mechanical work. The contractor for the heating and ventilating work was Mr. E. Rutzler, of New York City.



BASEMENT PLAN, SHOWING THE VENTILATING SYSTEM FOR THAT FLOOR ONLY.

Malleable Iron Companies controlling seventeen plants and manufacturing 85 per cent. of the output of the United States were recently consolidated in Detroit. The capital represented is reported to be between $16,000,000 and $20,000,000.

The Revised Health Laws of the State of Ohio, taking effect May 4, 1903, provide for a local board of health for each city and village, such board to be composed of five members serving without compensation, appointed by the mayor and confirmed by the council. In villages (incorporations having less than 5,000 inhabitants) the council may appoint a health officer instead of a board of health, such appointee to be approved by the State board of health.

Letter to the Editor.

Typhoid Fever and Oysters.

Sir: In August last there occurred a decided increase in the reported cases of typhoid in this city with a further increase in September, as shown by the following statement:

1901—	Jan.	Feb.	Mar.	Apr.	May.	June.	July.	Aug.	Sept	Oct.	Nov	Dec.
Cases	1	3	2	1	0	2	3	12	13	19	3	1
Deaths	0	0	1	0	0	1	0	0	0	1	0	0
1902—												
Cases	1	0	1	2	2	1	4	10	36	..	..	..
Deaths	1	0	0	0	0	0	1	1	2	..	..	..

The matter was deemed of such importance that the local Academy of Medicine, aided by the expert services of Drs. A. C. Abbott and Henry Leffmann, of Philadelphia, made a careful examination into the cause of this increase of typhoid. From their report, it appears that the pollution of oyster fattening beds in the vicinity of our sewer outfalls has been the chief source of the disease.

The importance of prohibiting the culture of oysters in close proximity to sewer outfalls is believed to be very generally overlooked by boards of health, in spite of the well known danger incurred; and as population increases and the natural off-shore oyster layings are depleted, the necessity for such restriction is increased.

The subject was taken up some six or eight years ago by the Local Government Board of Great Britain, and the report of Dr. H. T. Bulstrode, covering the shores of England and Wales, contains much interesting and valuable material. While layings located at a considerable distance from sources of contamination, although pollution is remotely possible, are passed by, a number situated in proximity thereto are condemned as unsafe; and the occasional cases of infection that come to light from time to time confirm us in the opinion that many oyster beds between the Chesapeake Bay and Cape Cod should be abandoned.

Yours truly,

Kenneth Allen.

Atlantic City, N. J., Nov. 30, 1902.

Personal and Obituary Notes.

Mr. Julian Kendrick has been re-elected city engineer of Birmingham, Ala.

Mr. Charles Hood has resigned as superintendent of the water-works of Burlington, Ia.

Capt. A. P. Adrian has resigned as county surveyor of New Hanover county, Wilmington, N. C.

Mr. Philip W. Moen, of Worcester, Mass., has resigned as second vice-president of the American Steel & Wire Co.

Mr. E. B. Thomas has been elected president of the Lehigh Valley Railroad Co., and of the Lehigh Valley Coal Co.

Mr. Louis F. Barton has been appointed a member of the board of water commissioners of Newburyport, Mass.

Mr. J. W. Bridge, has been made superintendent of the Uniontown, Pa., division of the Pittsburg, McKeesport & Connellsville Railway.

Civil Engineer, R. E. Peary, U. S. N., according to Washington reports, is to be assigned to duty at the New York navy yard, Brooklyn.

Prof. William Boughton, of Denison University, Granville, O., has been appointed professor of civil engineering in the West Virginia University at Morgantown, W. Va.

Mr. George H. Ross, for some years traffic manager of the Indiana, Illinois & Iowa Railroad, at Chicago, has succeeded Mr. Theodore C. Bates as president of the Union Bridge & Terminal Co., Kansas City.

Mr. Granbery Jackson and Mr. J. A. Omberg, Jr., city engineer of Memphis, Tenn., have entered into a partnership for general engineering work, particularly in municipal lines, with offices in the Randolph Building, Memphis.

Lieut.-Col. William R. Livermore, Corps of Engineers, U. S. A., has been ordered to relieve Capt. William V. Judson, Corps of Engineers, of his duties as engineer officer on the staff of the commanding general of the Department of the East.

The Civil and Irrigation Engineering Society of Colorado, organized recently at Fort Collins, with the following officers: President, Graham Fuller; vice-president, John Thistle; secretary-treasurer, Ralph Parshall; chairman general committee, Prof. S. L. Boothroyd.

Prof. C. E. Houghton, M. Am. Soc. M. E., professor of mechanical engineering at the Arkansas Industrial University, Fayetteville, Ark., has been appointed associate professor of mechanical engineering in the School of Applied Science, New York University. He was formerly an instructor in experimental engineering at Sibley College, Cornell University.

On account of the death of Joseph M. Wilson, announced in this column two weeks ago, the firm of Wilson Brothers & Co., architects and consulting engineers, has been reorganized by Messrs. Henry W. Wilson, John McArthur Harris and Howard S. Richards, the remaining members of the firm, under the new name of Wilson, Harris & Richards, with offices in the Drexel Building, Philadelphia.

The seventh annual meeting of the Brooklyn Engineers' Club was the occasion of a banquet at the Oxford Club, that city, December 11. Mr. J. V. Davies, Col. H. G. Prout and Mr. Foster Crowell were the first speakers, and addresses were made by the incoming and outgoing officers. President W. S. Ford was succeeded by A. J. Provost, Jr.; vice-president W. F. Tuttle by F. S. Woodward; secretary A. J. Provost, Jr. by Joseph Strachan; and treasurer G. C. Whipple by John Middleton.

The Engineers' Club of Philadelphia celebrated by a banquet on December 6 its attainment to the age of 25 years. Toasts were responded to by L. Y. Schermerhorn, Oberlin Smith, Admiral George W. Melville, James Christie, Charles F. Scott, Robert W. Lesley, John Birkinbine, Prof. Arthur W. Goodspeed, Wilfred Lewis, John C. Trautwine, Jr., and Peter Boyd, John Fritz, and Dr. Coleman Sellers were among the speakers. James M. Dodge, president of the American Society of Mechanical Engineers, was toastmaster. There were all told some 260 diners.

Sir William Chandler Roberts-Austen, assaymaster of the Royal Mint in London since 1882, died at the Mint November 22, aged 59 years. He entered the Royal School of Mines, in London, in 1861, with a view to becoming a mining engineer, but in 1869 became an assayer and has ever since been a leader in metallurgical investigations. He was the author of a general work on the subject and of many scientific papers. Much of his contributions has had a practical bearing, relating to the properties of iron and steel, to the hardening and tempering of steel, to the use of an automatic recording pyrometer and to the application of micro-photography. In 1880 he became professor of metallurgy at the Royal School of Mines, and was a member of a large number of societies. He was for two years president of the Iron and Steel Institute, an honorary member of both the Institution of Mechanical and of the Institution of Civil Engineers, one of the founders of the Physical Society of London, an honorary secretary of the British Association for the Advancement of Science.

The following candidates were announced elected December 3 to the various grades of membership in the American Society of Civil Engineers. Members: E C. Barhard, topographer, U. S. Geological Survey, Washington, D. C.; M. W. Cooley, mgr., National Contracting Co., Boston; R. L. Crump, designing engineer, Ford, Bacon & Davis, Kansas City, Mo.; G. R. Ferguson, assist. engineer, Dept. of Bridges, New York City; M. H. Gerry, Jr., gen. mgr., and chief engineer, Missouri River Power Co., Helena, Mont.; W. C. Hawley, chief engineer, Pennsylvania Water Co., Wilkinsburg, Pa.; E. T. Perkins, topographer, U. S. Geological Survey, Washington, D. C. Associate members: W. H. Adey, assistant engineer, Delaware & Hudson Co., Cohoes, N. Y.; Frederick Auryansen, chief draftsman, Atlantic Avenue Improvement, Brooklyn, N. Y.; G. M. Bacon, private practice, Salt Lake City, Utah; C. E. Bright, junior engineer, U. S. Engineer office, Tuscaloosa, Ala.; F. C. French, Atchison, Topeka & Santa Fé Railway, Davenport, O. T.; L. R. Gifford, assistant to structural engineer, Cambria Steel Co., Johnstown, Pa.; F. A. Hastings, assistant engineer, Keystone branch of American Bridge Co., Pittsburg, Pa.; W. N. Hazen, Frink & Hazen, Baltimore, Md.; Arthur Hirst, assistant engineer, Pencoyd plant, American Bridge Co., Pencoyd, Pa.; C. McK. Lewis, with Wm. Salomon & Co., New York City; T. A. Ross, resident engineer, Ping Li Railway, Shanghai, China; E. De Voe Tompkins, assistant engineer, Dept. of Bridges, New York City; E. D. Wickes, Bridge Dept., The Cuba Co., New York City. Associate: Stedman Bent, Overbrook, Pa. Juniors: W. E. Belcher, Pencoyd, Pa.; F. R. Berry, Joplin, Mo.; E. B. Brisley, New York City; R. B. Jackson, Ann Arbor, Mich.; F. J. Lynch, New York City; R. J. Mansfield, Pittsburg; N. A. Melick, New York City; C. J. Schumann, Troy, N. Y.

The Forest Reserve which is proposed in the Appalachian Mountain region of North Carolina, Kentucky, Tennessee, Virginia and West Virginia, is to be represented at the Louisiana Purchase Exposition by an elaborate relief map to be prepared by Mr. F. Cope Whitehouse, of New York.

Water Waste in Chicago is a large item, according to Superintendent H. O. Nourse, who states in his last annual report that a table showing the amount of water used for business and domestic purposes has been prepared which shows conclusively that 75 per cent. of the total pumpage goes to waste. It is stated that much of this waste is due to leaks in both water mains and service pipes, and, owing to the small appropriations for maintenance and for extensions, it has been impossible to make the necessary investigations and to replace mains laid 20 to 30 years ago.

The Lettering of Titles and important legends on drawings is expedited in the drafting rooms of the Bureau of Filtration, Philadelphia, by the use of standard letter sheets about 11x14 inches in size upon which are printed five standard alphabets and sets of numerals in plain Gothic type. These sheets also contain words most frequently occurring in titles and other places printed in the size of letter most frequently used for them. In this way a great deal of time usually spent in spacing is saved, for the draftsman can slip one of the standard letter sheets under his tracing and copy the words needed.

CONTRACTING NEWS

OF SPECIAL INTEREST TO

CONTRACTORS, BUILDERS, ENGINEERS AND MANUFACTURERS

OF ENGINEERING AND BUILDING SUPPLIES.

For Proposals see pages 21, 23, 24 and 36.

WATER.

West Rutland, Vt.—The House has passed a bill incorporating the West Rutland Water Co.

Lexington, Mass.—The citizens of this place, at a special town meeting held Dec. 1, voted to apply for admission to the Metropolitan water system.

Providence, R. I.—Comr. of Pub. Wks. Barclay in his annual report recommended the installation of a third pumping engine.

Portsmouth, N. H.—The Bd. of Aldermen has passed a resolution authorizing the Water Comrs. to use the unexpended balance of the sum realized from the recent sale of water bonds for the purpose of extending the city system to Freeman's Point.

Boston, Mass.—The following bids were opened Dec. 4 by the Metropolitan Water & Sewerage Bd., Frederic P. Stearns, Ch. Engr., for stripping 970,000 cu. yds. of surface soil from 700 acres of Wachusett Reservoir and depositing it in the shallow portion of the reservoir at Oakdale and in embankment of a road across reservoir at W. Boylston:

Items and Quantities.	Bruno, Salomone & Petitti, E. Boston. (awarded).	Newell & Snowling Cons. Co., Uxbridge.	Nawn & Brock, Boston.	Long & Little, Leominster.	Jere. J. McCarthy & Co., Boston.	Jones & Meehan, Boston.
Clearing and grubbing, 100 acres	$60.	$100.	$100.	$100.	$175.	$200.
Soil excav. A on plan, 450,000 cu. yds	.265	.27	.28	.29	.33	.35
Soil excav. B on plan, 310,000 cu. yds	.30	.33	.32	.33	.37	.37
Soil excav. C on plan, 210,000 cu. yds	.34	.39	.36	.39	.45	.40
Earth excav. (enlarge. of River), 65,000 cu. yds	.34	.39	.28	.30	.32	.50
Earth excav., 70,000 cu. yds	.34	.33	.24	.30	.36	.50
Rock excav., 15,000 cu. yds	1.70	2.00	2.50	1.50	1.65	2.50
Paving, on broken stone, 12,750 cu. yds	1.90	2.00	2.35	3.00	3.50	4.00
Paving, on coarse gravel, 10,750 cu. yds	1.75	1.80	2.60	2.75	3.00	4.00
Concrete masonry, 1,200 cu. yds	7.00	6.50	6.50	7.00	7.00	6.50
Overhaul, equivalent to 250,000 cu. yds., 100 ft	.01	.01	.01	.01	.01	.01
Total	$414,987	$449,300	$451,512	$466,412	$533,725	$585,500

Paterson, N. J.—Bids are wanted by the Jersey City Water Supply Co. until Dec. 22 for furnishing all labor and material necessary for building a brick lining in a tunnel 1,100 ft. long, as advertised in The Engineering Record.

Meadville, Pa.—Additional test wells are being drilled and will be utilized in the new water supply; they will be located 1½ miles west of the present pumping station.

Troy, N. Y.—Asst. Engr. Geo. M. Bull writes that the following bids were opened Dec. 5 by the Bd. of Contract and Supply: For 33-in. steel riveted pipe furnished and laid complete, prices are per ft. for 3,100 ft. in rock and 32,200 ft. in earth, respectively: The T. A. Gillespie Co., New York City, $6.80 and $7.40; total, $259,360. Carroll, Porter & Co., New York City, $8.10 and $9.60; total, $334,230. For furnishing cast iron pipe and castings, prices are per ton and per lb., respectively: Camden Iron Co., Camden, N. J., $28.65; total, $169,100. U. S. Cast Iron Pipe & Fdy. Co., Philadelphia, Pa., $29.40 and 3¼ cts.; total, $177,253. Warren Fdy. & Machine Co., New York City, $28.70 and 2.55 cts.; total, $172,324. Bids for a cast iron pipe line were as follows, in rock and earth, respectively: McDonough Const. Co., Troy, $5.50 and $4.81; total, $159,280. Behan & Cavanaugh, Troy, $7.00 and $3.50; total, $137,200. P. H. McKenna, Troy, $3.80 and $2.42; total, $91,640. Frank M. Lewis, Troy, $2.50 and $1.65; total, $62,200. P. H. Harrison Sons' Co., Troy, $4.12 and $2.85; total, $106,822.

Schenectady, N. Y.—A correspondent writes that bids are about to be asked for furnishing 500 meters. J. H. Amo, Secy. Water Comrs.

Tottenville, N. Y.—Bids are wanted Dec. 18 for furnishing building and installing a new boiler and appurtenances at the Pumping Station of the Tottenville Water Works, Boro. of Richmond. Robt. Grier Monroe, Comr. of Water Wks., N. Y. City.

Laurel Springs, N. J.—The Laurel Springs Water Co., registered office Camden, has been incorporated, with a capital of $100,000, to supply water to Laurel Springs and neighboring villages in Gloucester Township. The incorporators are: Sam. S. Cord and Alex. Tomlinson, of Laurel Springs; Geo. Pfeiffer, Jr., of Camden, and others.

Hyndman, Pa.—The Citizens Water Co. has been incorporated, with a capital of $15,000.

Allentown, Pa.—In a recent message to the City Councils Mayor Lewis recommended that work be stopped at Schantz's Spring, in view of the apparently limited supply of water, and that filtration be adopted.

New Castle, Del.—The taxpayers are considering means to borrow money by bonding the city for the purpose of installing new water works that shall be owned by the city in 20 years.

Pittsburg, Pa.—A resolution is before the Councils Finance Com., providing for the appropriation of $200,000 for the construction of water mains in the 22d Ward.

The Council has passed the resolution authorizing the Filtration Com. to employ an engineer to furnish estimates of the total cost of a filtration plant.

Trenton, N. J.—The Bd. of Health has adopted the recommendation of Dr. Alton S. Fell, Health Inspector, urging that a filtration plant be installed at the reservoir.

Yonkers, N. Y.—The Bd. of Water Comrs. has now under consideration the construction of a filtration plant near the tube well station.

Rochester, N. Y.—The Bd. of Aldermen has overridden Mayor Rodenbeck's veto and sustained the ordinance authorizing Comr. McClintock to purchase Cobb's Hill as a site for a reservoir.

Newark, N. J.—Engr. Sherrerd announced, at a meeting of the Bd. of Works' Committees, held Dec. 9, that the Edison Electric Storage Battery Co. had agreed to purchase water from Newark for its plant in the Silver Lake section of Belleville Township; the Engr. was authorized to lay the necessary mains for this extension.

Montclair, N. J.—The Town Council has granted the request of the Newark Bd. of Wks. for permission to lay a 60-in. pipe for a water main through Alexander Ave., Grove St. and Watchung Ave.

East Orange, N. J.—The City Council on Dec. 8 voted to reject the award of the Condemnation Comrs. fixing $425,000 as the value of and the price to be paid for the plant of the Orange Water Co.

Richmond, Va.—The Board of Aldermen on Dec. 9 concurred in the action of the Common Council in voting an issue of $405,000 bonds with which to erect settling and coagulating basins to provide the city with clear water, and construct a stand pipe in the Lee Dist. to increase the pressure in that section.

Columbus, Ga.—Robt. L. Johnson, Supt. of Pub. Wks., writes that the citizens of this place on Dec. 4 voted favorably, by an overwhelming majority, on the proposition to issue $250,000 bonds for the purpose of building water works. This means that the city will proceed at once with the detail plans and arrangements for the construction of a new system of Water Works to be owned and operated by the city.

Barnesville, Ga.—Bonds to the amount of $10,000 have been voted for the purpose of enlarging and improving Gordon Institute, the water and electric light plants.

Chicago, Ill.—Bids are wanted Dec. 24 for furnishing material and remodelling the tunnel system of the Chicago Ave. Pumping Station, involving the construction of 3 shafts, 12 ft. internal diameter, each about 90 ft. deep; about 180 ft. of circular brick tunnel, 6 ft. internal diameter; about 458 ft. of circular brick tunnel, 5 ft. internal diameter, and the setting and placing of a 6 ft. gate valve. F. W. Blocki, Comr. of Pub. Wks.

West Milton, O.—Corp. Clk. John Coate writes that the contract for constructing a system of water works (bids opened Dec. 1) has been awarded to P. H. Porter, of Clinton, Ky., for $23,300, complete.

Bloomington, Ill.—City Engr. Elmer Folsom writes that water mains, sewer and asphalt pavement will be laid on Wood St. and Morris Ave.

Wyandotte, Mich.—Mayor Bishop is said to be in favor of the issue of $175,000 bonds for the construction of a sewerage system, the extension of the water and lighting systems.

Boone, Io.—The City Council has authorized City Engr. Chas. E. Russell to prospect for the purpose of obtaining a water supply from shallow wells.

Negaunee, Mich.—This city is contemplating the renewal of its boiler plant at the water works; the present plant, which consists of 2 60-in.x16 ft. and 1 66-in.x17 ft. horizontal tubular boilers, has been condemned. Cyril Houle, Mayor; Wm. H. Mitchell, Recorder.

Thief River Falls, Minn.—The City Council is considering the subject of water works and a sewer system.

Cincinnati, O.—Plans and specifications have been completed by Gustave Drach, and bids will probably soon be asked for construction of western pumping station of the new water works. Probable cost about $500,000.

Wausau, Wis.—A filtering plant is recommended by Prof. Erasmus G. Smith, of Beloit Sanitary Laboratory, for the city water system, at a cost of $25,000.

Kansas City, Mo.—The sum of $11,148 has been appropriated by the lower house of the Council to defray the expenses of laying water mains and hydrants on several streets.

Supt. Goodwin, of the water works, is preparing to lay before the Bd. of Pub. Wks. the complete plans and specifications for the proposed aqueduct from Quindaro to the Turkey creek pumping station. Said plans contemplate the construction of an aqueduct of concrete, with a diameter of 5 ft. on the inside. The estimate made by the expert engineers of the cost of the proposed aqueduct is in the neighborhood of $225,000.

Baton Rouge, La.—The city has offered to purchase the plant of the City Water Works Co. for $75,000.

Walnut Ridge, Ark.—S. C. Dowell, of this place, writes that J. D. Goldman, of St. Louis, Mo.; S. Riegler, of Walnut Ridge, and he are organizing a company, with a capital of $100,000, to construct water works, electric lights and 2 miles of street railway for Walnut Ridge and Hoxie. Offices to be in Walnut Ridge.

Geary, Okla. Ter.—City Clk. J. M. Waterman writes that this city will build water works, at a cost of $30,000, and bids for same will be wanted as soon as plans and specifications are completed.

Watonga, Okla. Ter.—The question of issuing $16,000 water-works bonds is reported to have carried at the recent election.

Schulenburg, Tex.—The City Council has contracted with the Guenther Fdy. Co., of San Antonio, for the construction of a system of water works for which $11,000 bonds were voted.

Ft. Columbia, Wash.—Capt. Geo. L. Goodale, Constructing Q. M., U. S. A., writes that the contract for constructing a water and sewer system has been awarded to Ferguson & Houston, of Astoria, Ore., for $20,971.

Boise, Idaho.—The Idaho-Iowa Lateral & Reservoir Co. has decided to increase its capital stock from $100,000 to $250,000. Proposed improvements are said to include the construction of several reservoirs. W. C. Annett, Mgr.

State Engr. D. W. Ross is reported to have about completed preliminary surveys for a number of reservoir sites in this State, in accordance with the provisions of the new national irrigation law.

Richfield, Utah.—The City Council has instructed P. D. Schroeber, of Salina, Utah, to make surveys, plans and specifications for the proposed water works system.

Durango, Colo.—This city is reported to have voted, at the special election held Dec. 2, to issue $150,000 bonds for a new gravity system of water works. It is proposed to buy water rights and reservoirs on the Florida River; the present water supply is from Las Animas River.

Nampa, Idaho.—It is stated that bids are wanted Dec. 30 for the purchase of $10,000 bonds for the construction of water works. A. L. Springer, City Clk.

Ogden, Utah.—The City Council has instructed the Com. on Water Supply to secure options on all artesian lands in Ogden Valley, within 2 miles of the present water supply.

Saratoga, Wyo.—A new ditch company has been organized here, which is to be known as the Boulder Canal Co., to operate in Fremont and Carbon Counties. Capital stock, $60,000. Incorporators: W. S. Adams, E. B. Steadman, W. H. Butler, and others.

Salt Lake City, Utah.—Bids will be received by the Bd. of Pub. Wks. until Dec. 26 for constructing all water mains as may be ordered by the City Council from Jan. 1 to Oct. 31, 1903. The approximate quantities of pipe to be furnished and laid, including excavating, special castings, hydrants, valves, etc., are as follows: 15,000 lin. ft. of 6-in., 5,000 lin. ft. of 8-in. and 1,600 lin. ft. of 10-in. Louis C. Kelsey, City Engr.

Mt. Vernon, S. D.—A water works system is said to be projected for next season.

Cody, Wyo.—The Town Council is having surveys and estimates made for a system of water works. Probable cost, $16,000.

Farmington, New Mex.—Bids are reported to be wanted for the enlargement of the Independent Irrigating Ditch, increasing its width 2 ft. from the head to the Waite headgate. Address Otis L. Waite, Secy., Farmington.

Helena, Mont.—At the election, held Dec. 8, it was voted to bond the city to the amount of $615,000 for the purpose of installing a municipal water plant, for fire and sewerage purposes.

Boise, Idaho.—D. R. Cameron, of the Cameron Lumber Co., operating at Harrison, has asked the State Land Bd. for a franchise for the improvement of Couer d'Alene River and its tributaries. Estimated cost of improvement, $66,000.

Idaho.—Local press reports state that F. H. Buhl, of Sharon, Pa.; S. B. Milner and Frank Knox, of Salt Lake City, Utah, and I. B. Perinne, of Blue Lakes, Idaho, are interested in an electrical power deal at Twin Falls, Idaho, which may mean an expenditure of $1,500,000. The scheme is to dam Snake River at Twin Falls and construct a system of canals which will irrigate 270,000 acres, for which work preliminary surveys are being made.

Canon City, Colo.—This city is considering the proposition to secure water from the artesian wells near Chandler; it would probably require about 7 miles of pipe line to bring the water to this city.

Denver, Colo.—The Denver Union Water Co. is reported to have purchased 100 acres of land on the Platte River, and work will begin at once on a reservoir to have a capacity of 300,000,000 gal.

Wyoming.—A. J. Parshall, of Cheyenne, the engineer in charge of the investigation work for the U. S. geological survey, is making a thorough investigation of the country through which Platte River flows in Wyo., with a view to discovering possible reservoir sites where surplus waters from this stream can be stored for irrigation purposes.

Marieville, Que.—It is stated that bids are wanted Dec. 22 for constructing water works. Dupont & Leduc, Engrs., 35 St. James St., Montreal, Que.; G. Bombardie, Secy.

La Cananea, Mex.—W. T. Hiscox & Co., 26 Cliff St., New York City, have received the contract for supplying material for a 10-in. pipe line, 10 miles long, for the Greene Consolidated Copper Co., 377 Broadway, New York City, at its mines, La Cananea, Mexico; amount of contract stated to be about $60,000.

SEWERAGE AND SEWAGE DISPOSAL.

New Britain, Conn.—A correspondent writes that this city will let a contract for a tunnel 1,000 ft. long in connection with its sewage disposal works.

New London, Conn.—The Bd. of Sewer Comrs. is considering the report, of Engr. Walter H. Richards on the sewering of Ocean Beach Park, which includes a plan for the work decided upon after a series of surveys and tests in regard to tide currents. An 18-in. outfall sewer of wood pipe will be necessary for a distance of 1,013 ft. Total estimated cost $9,000.

Jersey City, N. J.—The Bd. of Street & Water Comrs. has directed Ch. Engr. Van Keuren to prepare specifications for the reconstruction of the sewers in Belmont and Gardner Aves. Probable cost, $15,000.

A resolution has been adopted by the Bd. of S. and W. Comrs. asking the Bd. of Finance to appropriate money for the reconstruction of the following sewers: Bay St., estimated cost, $15,600; Second St., $7,428; Van Vorst and Essex St., $8,085.

Plans have been prepared for a 6-ft. steel sewer to help carry off, in lower Jersey City, part of the sewage and surface water of Ravine Road sewerage district.

Philadelphia, Pa.—Bids will be received until Dec. 16 by the Dept. of Pub. Wks., Bureau of Highways, for furnishing material and doing the following work: Repairing sewers, drain pipes, inlets, etc., during the year 1903; for general repairs to sewers; for general repairs to bridges; for grading, paving, repaving or repairing sidewalks; for furnishing and delivering iron pipe; for the maintenance of unpaved and macadamized public highways; furnishing and delivering iron pipe; terra cotta pipe, cement, sand, gravel, etc. Wm. C. Haddock, Dir.

Bradley Beach, N. J.—The Common Council is stated to have received the following bids for the construction of sewers, estimated to cost $23,800: W. J. McCloud of Elizabeth, $24,532; Harrison Const. Co., of Newark, $25,370, and Jas. P. Hall, Jersey City, $46,117.

Yonkers, N. Y.—The Common Council has ordered plans and specifications prepared for Lamartine Ave. and North B'way relief sewer; North B'way, sewer between High St. and Glenwood Ave., Ashburton Ave. relief sewer, Elm St. and Van Cortlandt Park Ave. sewer and Greenvale Ave. sewer.

Canonsburg, Pa.—Bids are wanted Dec. 22 for constructing 410 ft. of 2 and 3 rings. 60 ins. brick sewer. T. M. Reese, Pres. of Council. Jas. S. Haring, Engr., Crafton.

Chambersburg, Pa.—This city is considering the voting for a $30,000 loan for municipal improvements, including lighting and sewerage.

Wilmington, Del.—Engr. of Sewers T. Chalkley Hatton recommends the construction of an 18-in. pipe sewer in 13th St. from Heald St. to Brandywine Creek, as a temporary relief from floods beyond 11th St. bridge, in the spring of the year.

Camden, N. J.—City Engr. Farnham has presented to the City Council's Street Com. a plan for sewering the meadows at an estimated cost of $50,000.

Indiana, Pa.—The Boro. Council has passed ordinances providing for the erection of a complete system of sewers for this place, and filter beds for 6 acres in area. The latter will be located 2 miles south of the town.

Jersey City, N. J.—The contract for constructing a main branch sewer in Marcey Ave. has been awarded to Chas. O'Neill. Estimated cost, $11,275.

Brooklyn, N. Y.—The local administration expects to take up and put through at an early date next year a complete system of relief sewers in this Boro. at an estimated cost of $343,000.

Anglesea, N. J.—The following bids were opened Nov. 18 by Mayor Augustus Hilton, for the construction of a sewerage system; Wm. H. Boardman, Engr.: A, B. F. Sweeten & Son, Camden, N. J., $17,291 (awarded); B, Jas. O'Neil, Jr., Burlington, N. J., $17,745; C, Robt. Hand, Cape May, N. J., $17,437; C, Cahill & Co., Newark, N. J., $31,026. For detail bids see accompanying table.

Items.	A	B	C	D
Pipe—23,370 ft. 8-in....	$0.42	$0.43	$0.42	$0.60

Outfalls, each	25.00	25.00	12.50	100.00

Fernandina, Fla.—Bids will be received until Jan. 7 by J. E. Stark, City Clk., for constructing a sewerage system. The work includes approximately, 1,810 ft. of 6-in., 28,700 ft. of 8-in., 2,270 ft. of 10-in., 2,540 ft. of 12-in. and 300 ft. of 15-in. sewer, 144 ft. of 16-in. and 12 ft. of 8-in. cast iron pipe, 30 manholes, 35 lampholes, 24 flush tanks, etc. Roland Woodward, Engr.

Bartow, Fla.—City Clk. W. O. Stanley writes that on Nov. 11 it was voted to issue $15,000 bonds for the construction of an electric light plant and sewerage system.

Atlanta, Ga.—Rudolph Hering, of New York City, has been engaged by this city to recommend a plan for the improvement of the sewerage system and the disposal of sewage.

Fernandina, Fla.—The City Council has accepted plans and specifications for a sewerage system for the entire city, and it is stated that contracts for same will be let at once. Estimated cost, $26,000.

Cincinnati, O.—Bids will be received by the Bd. of Pub. Service until Jan. 2 for furnishing material and constructing a trunk sewer and drain in a portion of Torrence Road. Geo. F. Holmes, Clk.

Dixon, Ill.—Mayor F. A. Truman (temporary address Colfax, Ia.) writes that only one bid was received for sewers recently advertised, and as more contracts are to be let it has been decided to postpone letting until Feb.

Bloomington, Ill.—See "Water;" also see "Paving and Roadmaking."

Walnut, Ill.—Engr. P. C. Knight, of Pontiac, Ill., writes that the letting of the contract for enlarging and repairing the main ditch of Dist. No. 1 has been postponed until some time in Jan. It is estimated that there will be 634,380 cu. yds. of excavation. Jas. Foley, Chmn. Drainage Comrs. of said Dist.

Chicago, Ill.—The Bd. of Local Improve. has ordered the construction of a system of brick sewers in Addison and W. Madison Sts. and Western Ave., to cost $29,000.

St. Bernard, O.—The St. Bernard Improvement Asso. has recommended to the Village Council that a trunk sewer be built through St. Bernard and arrangements be made with other villages of the valley to extend the system all along Carthage pike. Estimated cost, $200,000.

Thief River Falls, Minn.—See "Water."

Cincinnati, O.—The Bd. of Pub. Service has awarded sewer contracts as follows: State Ave. and Lehman Road to Henry Frank for $13,990; Torrence Road, to A. J. Henkel & Bros., for $11,067.

The Bd. of Pub. Service has instructed the Ch. Engr. to prepare plans and specifications for sewers in the northwestern part of Price Hill, which will cost in the neighborhood of $30,000.

South Orange, N. J.—The following bids were opened by the Village Trus. on Dec. 2 for the construction of a sewerage system; Alexander Potter, of New York City, Ch. Engr.:

Items and Quantities.	Ludwig Batt, So. Orange (awarded).	David Peoples, Phila., Pa.	Union Bldg. & Const. Co., Passaic, N. J.	T. J. Shea, Quincy, Ill.	John F. Shanley, Newark, N. J.	Headley & Christie, Newark, N. J.	Harrison Const. Co. Newark, N. J.	Jas. Conway, Newark, N. J.

Asbury, Park N. J.—The Beach Com. of the Bd. of Aldermen has decided to accept the offer of Jas. A. Brsdley to sell the beach front and the sewer system for $150,000. It is stated that the city authorities contemplate inviting bids for plans and the construction of a new steel board-walk, casino, music stand and bathing establishment, in anticipation of the sale of bonds to be voted upon probably in the near future.

Des Moines, Ia.—The lowest bids received Dec. 2 for the construction of 3,444 ft. of sewer on 12th St. is stated to, have been from O. P. Herrick at $1.37 per lin. ft.

Columbus, O.—Bids are wanted Jan. 6 for the construction of sewers, as advertised in The Engineering Record.

Gibson City, Ill.—The city officials recommend the construction of a sewer system similar to the system in Urbana.

Wyandotte, Mich.—See "Water."

St. Paul, Minn.—An extension of the main sewer along Concord St. has been ordered at a cost of $7,000.

Springfield, Ill.—It has been agreed by the Bd. of Pub. Improv. to recommend the placing of an 18-in. sewer pipe in 2d St.

Ottawa, Ill.—At a recent mass meeting a vote was taken in favor of the construction of a new sewer system on the west side.

Clinton, Ill.—Engr. J. G. McInish, of Bloomington, Ill., writes that the following bids were opened Nov. 22 by the drainage commissioners of Friend's Creek Special Drainage Dist., in the Counties of De Witt and Piatt, for the construction of the main drainage channel in said district; *a*, new channel; *b*, old channel: J. W. Boyer, Manchester, Ind., *a*, 6.9 cts.; *b*, 7 cts.; R. H. McWilliams, Mattoon, Ill., *a*, 6 cts.; *b*, 6 cts.; Canal Const. Co., Chicago, Ill., *a*, 7.5 cts.; *b*, 7.5 cts.; Elkhart Const. Co., Elkhart, Ind., *a*, 7.5 cts.; *b*, 9.5 cts.; R. N. Andrews Co., Hamilton, O., *a*, 8.23 cts.; *b*, 8.23 cts.; John McAndrews, Bradley, Ill., *a*, 6⅞ cts.; *b*, 6⅞ cts.; John A. Brumbaugh, Elkhart, Ind., *a*, 8 cts.; *b*, 8 cts.; J. E. Rogers & Co., Tuscola, Ill., *a*, 8 cts.; *b*, 10 cts.; Chas. R. Lewis, Tuscola, Ill., *a*, 7 cts.; *b*, 7 cts.; total, $12,822 (awarded); Pollard, Goff & Co., Champaign, Ill., *a*, 6⅔ cts.; *b*, 6⅔ cts.; G. A. McWilliams, Melvin, Ill., *a*, 6.8 cts.; *b*, 7.1 cts.; Jos. Lewis, Atwood, Ill., *a*, 10 cts.; *b*, 11 cts.

Kansas City, Mo.—A correspondent writes that bids will be received until Dec. 16 for constructing 4,000 ft. of pipe sewers in Sewer Dist. No. 132, cost $5,000; also for constructing 25,000 ft. of pipe sewers, 5,000 ft. of brick sewers, 102 manholes, 62 catch basins, 7 flush tanks in Sewer Dist. No. 211, cost $60,000. R. W. Waddell, City Engr.

Lawton, Okla. Ter.—Bids are wanted Jan. 5 for furnishing material and constructing a sewer system. D. A. Jacobs, City Clk.; W. S. Shields, Designing Engr., Rm. 1715 Marquette Bldg., Chicago, Ill.

Lake Charles, La.—Plans and estimates for a system of sanitary sewerage have been prepared by John W. Maxcy, of Houston, Tex., and submitted to the City Council. Approximate cost of work, $240,000.

Houston, Tex.—The City Engr. is said to be preparing plans and specifications for a storm water sewer 9 ft. in diameter, which is to drain one section of the city, beginning with Austin St. and extending to the Bayou.

Salt Lake City, Utah.—Bids will be received by the Bd. of Pub. Wks. until Dec. 26 for constructing all pipe sewers that may be ordered by the City Council from Jan. 1st to Oct. 31, 1903. The approximate quantities of pipe to be furnished and laid, including excavatings, manholes, flush tanks, etc., are as follows: 30,000 lin. ft. of 8-in., 1,600 lin. ft. of 10-in. and 1,600 lin. ft. of 12-in. Louis C. Kelsey, City Engr.

Fresno, Cal.—City Engr. I. Teilman writes that this city contemplates building 2½ miles of 30-in. brick sewer to take the place of an 18-in. pipe sewer which is too small. Probable cost, $30,000.

Ft. Columbia, Wash.—See "Water."

South Omaha, Neb.—It is proposed to construct a 5-ft. brick sewer from 20th and N Sts. to the river. Probable cost, $25,000.

Seattle, Wash.—The City Council has ordered the construction of sewers on Madrona Place and other connecting streets, which, according to the estimate presented by the city engineer, will cost $30,000. The construction of a system of sewers for the Lake Dell improvement, has also been ordered at a cost of $19,000.

Listowel, Ont.—The contract for building a sewer and sewage disposal works has been awarded to P. Pigeon, of Sebringville, for $5,710.

BRIDGES.

Providence, R. I.—A bill has passed the House, authorizing this city to repair the bridge on the east side of Exchange Pl., at a probable cost of $120,000.

Boston, Mass.—Wm. T. Pierce, Engr. Metropolitan Park Comn., writes that the following bids for constructing Wellington Bridge (pile structure), Middlesex Fells Parkway, were received by the Metropolitan Park Commission Dec. 1: W. H. Ellis, Boston, $115,900; Jos. Ross, Boston, $111,900; T. E. Ruggles, Boston, $100,661; Benj. Young, Chelsea, $99,700; Wm. L. Miller, Boston, $93,000; Lawler Bros., Charlestown, $89,000; Mayo Contracting Co., Boston, $86,285; Jones & Meehan, Boston, $86,000 (awarded). The bridge will be over 800 ft. long, and the contract calls for about 1,000,000 ft. of hard pine and spruce lumber, and about 1,500 oak piles.

York, Pa.—Bids are wanted Dec. 16 for constructing a bridge in the 12th Ward and one in the 8th Ward. John R. Lafean, Chmn. Highway Com.

Yonkers, N. Y.—Plans and specifications have been accepted for a modern highway bridge, with a paved roadway, to be built across the N. Y. & Putnam Ry. at Caryl Ave.

Pulaski, Pa.—The Bd. of Pub. Bldgs. and Grounds, at Harrisburg, has selected Herman Laub, Lewis Blk., Pittsburg, to prepare plans and specifications for the State bridge to be built in this city. The Bd. of Viewers recommended the building of a 2-arch stone bridge, to cost about $20,000.

Taylorsville, Pa.—Press reports state that the Baltimore & Ohio R. R. Co. has decided to build a stone bridge across Buffalo Creek west of Taylorsville Station, on the Pittsburg & Wheeling division, estimated to cost about $50,000.

Chestertown, Md.—The Comrs. of Kent and Queen Anne Counties are reported to have under consideration the repair of bridge across Chester River, in this city. It is proposed to put in a new draw, etc.

Philadelphia, Pa.—See "Sewerage and Sewage Disposal."

Jeannette, Pa.—The Town Council has voted to construct an iron bridge at 7th St.; also to construct an arch under the tracks of the Pennsylvania R. R. at 3d St.

York, Pa.—The Co. Comrs. have approved the action of the Grand Juries in recommending the building of a bridge at Richland Ave.

Sayre, Pa.—Local press reports state that the Court has approved the recommendation of the Grand Jury that an iron bridge be built across Susquehanna River, in this borough, at a probable cost of $10,000, and the Co. Comrs. will, according to reports, soon ask for bids for constructing same.

Lykens, Pa.—Viewers appointed to report on the building of a county bridge across Rattling Creek, in this borough, have decided in favor of constructing said bridge.

Rensselaer, N. Y.—The officials of the Central Hudson R. R. are said to be contemplating the building of a new bridge across the R. R. tracks at East Greenbush turnpike, to replace present structure, which is in poor condition.

It is stated that petitions are being circulated asking for the building of a wagon and foot bridge at Third Ave.

Roesslerville, N. Y.—Press reports state that the N. Y. C. & H. R. R. R. Co. is about to construct a 9-track bridge across Schenectady turnpike in this city. The bridge is to consist of 2 steel spans, and is to have stone abutments.

Harrisburg, Pa.—The Viewers appointed to report on the rebuilding of the county bridge across Schuylkill River in Schuylkill County, at Shollenberger's Crossing, have filed their report recommending the building of a steel truss structure.

Stroudsburg, Pa.—The Co. Comrs. and the Stroudsburg Passenger Ry. Co. are reported to have reached an agreement whereby the Ry. Co. is to construct a bridge, for said railway, across Pocono Creek.

McKees Rocks, Pa.—It is reported that a petition is in circulation asking for the building of a bridge, 1,200 ft. long, to cross the P. C. & Y. and the Ohio connecting railroads and Chartiers Creek.

Moravia, Pa.—The Court has adopted the report of the Bd. of Viewers in favor of opening the new road to Moravia, which, it is stated, will necessitate the construction of a $30,000 bridge across Beaver River.

New York, N. Y.—The following bids were opened Dec. 11 by G. Lindenthal, Comr. Bridges, for constructing the Manhattan tower foundation of Manhattan bridge (No. 3) over the East River. All bidders of New York City. Item A is work complete above el. —79.15; B, between el. —79.15 and —83 (1,602 cu. yds.): C to G, 1,664 cu. yds. each bet. planes 4 ft. apart down to el. —103:

New York, N. Y.—Bids are wanted Dec. 22 for rebuilding Bank Rock Bridge in Central Park. Wm. R. Willcox, Comr. of Parks.

Camden, N. J.—The Bldg. Com. of the Bd. of Freeholders is reported to be contemplating the elevating of Federal St. bridge.

Augusta, Ga.—A bill has passed the House, authorizing the building of a bridge across Savannah River at Sand Bar Ferry.

Metropolis, Ill.—Reports state that a railway bridge is to be built across Ohio River by the St. Louis & San Francisco R. R. in this city.

Oshkosh, Wis.—Erickson & Lehman have prepared plans for a single 60-ft. span steel bridge, which it is proposed to build across Sawyer Creek, at a probable cost of $6,000.

Lancaster, O.—The Co. Comrs. are said to be contemplating the building of a bridge across Hocking River.

Vinton, Io.—It is stated that a bridge is to be built across Cedar River at Vinton, in connection with the Vinton, Belle Plaine & Independence Ry. J. D. Wardle, Engr., Cedar Rapids.

Bridgeport, W. Va.—Local press reports state that bids will be received by F. S. Rice, City Clk., for building a bridge across Wheeling Creek at West St., to cost about $22,000.

Joliet, Ill.—The Boards of Will and Grundy Counties are contemplating the building of a $25,000 bridge across Kankakee River.

Huron, O.—The Lake Shore Electric Ry. Co. is reported to have under consideration the building of a bridge in this city.

Terre Haute, Ind.—Local press reports state that bids will be received by the Co. Comrs. until Dec. 31 for constructing 24 bridges in various parts of the county; 19 of the structures are to be combination steel and concrete, and to range from 12 to 40 ft. in length, and the other 5 are to be steel bridges, ranging from 80 to 110 ft. in length.

Bloomfield, Ind.—Bids will be received by the Bd. of Co. Comrs. until Jan. 6 for constructing the steel superstructure of a 100-ft. bridge in Richland Township, and for constructing the substructure and steel superstructure of a 40-ft. bridge in Taylor Township. Harvey L. Doney, Co. Aud.

Peoria, Ill.—A correspondent writes that bids will be received in January for constructing a concrete bridge across Farm Creek.

Detroit, Mich.—The building of a railroad bridge across Detroit River is reported to be again under consideration.

East Grand Forks, Minn.—The City Council and County Comrs. have agreed to build a bridge across Red Lake River, between Washington and Michigan Aves.

Cincinnati, O.—Press reports state that the Court had determined that the Cincinnati & Indiana Western R. R. Co. may construct at Harrison Ave., in Millcreek bottoms, a temporary wooden trestle, to be replaced in a period agreed upon by the said company and the Cleveland, Cincinnati, Chicago & St. Louis Ry. (over whose tracks it is to cross) by a 500-ft. steel span, so constructed that it will not interfere with the traffic or handling of freight by the C., C., C. & St. Louis Ry. This steel span, the railroad experts are reported to have stated, will cost $75,000.

Springfield, O.—The Park Bd. is reported to have under consideration the erection of a viaduct over Bechtle Ave., in Snyder Park, for the use of the Sidney & Piqua Traction Co.

Hempstead, Tex.—Reports state that the railroad bridge in this city, belonging to the Houston & Texas Central Ry. Co. will be repaired, or possibly a new structure erected.

Meridian, Miss.—It is stated that bids are wanted for a double bridge to be built across the branch of the Marion and Livingston road near Jim Pack Place. B. V. White, Clk.

McKinney, Tex.—The Comrs. Court is reported to have ordered the building of 2 iron bridges, each to have a 50-ft. span.

Lawrence, Kan.—A press report states that the citizens have voted to erect an iron bridge across Stranger Creek in Easton Township.

Tacoma, Wash.—The Council Com. has decided to construct a wood and iron bridge across Puyallup River at 21st St., at a cost of $12,000.

Dale, Colo.—Press reports state that the largest bridge on the Florence & Cripple Creek R. R. has been destroyed by fire. The bridge is situated between Dale and Adelaide.

San Jose, Cal.—Co. Surveyor J. G. McMillan writes that bids for the Endmondson Ave. bridge have been rejected.

Olivet, S. D.—Bids will be received by the Co. Comrs. until Jan. 7 for constructing 2 steel bridges as follows: 1 across Twelve Mile Creek to have 1 span 40 ft. long, and roadway 16 ft. wide, the other to be built across Lone Tree Creek, to have 1 span, 80 ft. long, and roadway 16 ft. in the clear. D. D. Wipf, Co. Aud.

Colorado Springs, Colo.—Local press reports state that the Santa Fe R. R. Co. will construct a steel bridge, 80 ft. wide, at Costilla St.

PAVING AND ROADMAKING.

Philadelphia, Pa.—See "Sewerage and Sewage Disposal."

New York, N. Y.—Bids are wanted Dec. 16 for regulating, regrading, reflagging and recurbing a portion of Edgecombe Ave. and for regulating, grading, curbing and flagging portions of 171st and 172d Sts. Jacob A. Cantor, Boro. Pres.

Baltimore, Md.—Asst. Engr. Jas. A. Paige writes that the lowest bid opened Dec. 3, by the Bd. of Awards, for work on Northwest St., was from Daniel Sullivan as follows: brick paving on 4-in. concrete, $1.97 per sq. yd.; cobble paving in cross streets, 80 cts. per sq. yd.; cobble repaving, 40 cts.; 4½-in. curb, 65 cts. per lin. ft.; old curb redressed and reset, 18 cts. per lin. ft.; old curb redressed in place, 10 cts. per lin. ft.; 4½-in. headers, 45 cts. per lin. ft.; grading, 33 cts. per cu. yd.; total, $10,189. Other bids received were from Owen Patterson at $11,783, and Filbert Paving & Const. Co. at $11,713.

Elmira, N. Y.—The Bd. of Supervisors has adopted the Grand Central Ave. route as the route for proposed macadam road between Elmira and Horseheads. Chas. Chamberlain, Chmn. Special Com.

Reading, Pa.—The Mt. Penn Speedway & Boulevard Co. has been organized by Wm. Abbott Witman, H. T. Shick and Calvin M. Dechant, C. E., to construct a driveway about 3 miles long and 50 ft. wide, along Mt. Penn. Capital stock of Co., $30,000.

Cape May, N. J.—Former Senator Wm. Flinn, Peter Shields and Chas. Fitzgerald, of Pittsburgh; Ellis D. Thompson, of Philadelphia, and Frank G. Edwards, of Bristol, Pa., have been considering with the City Council details of improvements of east Cape May and Two Mile beach at a proposed outlay of several million dollars. They asked that the city expend $100,000 on the beach boulevard along the front of the property. A 20-ft. steel boardwalk is said to have been agreed upon.

Union Center, N. Y.—Surveys are about to be made for a macadam road from Union Center to Maine.

Syracuse, N. Y.—Bids were opened Dec. 8 for paving Grape St., and the lowest prices were, according to local press reports, from the Syracuse Improvement Co., as follows: For Trinidad asphalt, $53,714, $51,935 and $54,011; for brick the bids of said company were: $59,078, $57,299, $65,328 and $65,625.

Brooklyn, N. Y.—Bids will be received by J. Edw. Swanstrom, Boro. Pres., until Dec. 24 for furnishing material and repaving with asphalt on a concrete foundation a portion of Bocrum Place, requiring 1,390 sq. yds. of asphalt; for paving with asphalt on a concrete foundation, a portion of Hinsdale St., requiring 7,825 sq. yds. of asphalt and 1,090 cu. yds. of concrete; also for furnishing and delivering 1 stone crusher and 2 steam road rollers.

Long Island City, N. Y.—Bids will be received until Dec. 20 by Joseph Cassidy, Boro. Pres., for furnishing material and regulating grading, curbing, and paving with asphalt (about 3,100 sq. yds., including binder course), on a concrete foundation, a portion of St. Nicholas Ave.; for furnishing material and repairing and maintaining asphalt pavement on a concrete foundation (about 4,200 sq. yds., including binder course), a portion of Fulton St. Bids will also be received at the same time for furnishing and delivering to the Bureau of Highway 5,000 cu. yds. of screenings of trap rock, in the 5th Ward, Boro. of Queens.

Rodman, N. Y.—This town has petitioned for the construction of 2 sections of road each 2½ miles long, under the Higbee-Armstrong law.

Pittsburg, Pa.—The Allegheny County Comrs. propose to sell only $100,000 worth of the $550,000 road bonds recently offered for sale, the remainder to be sold early next year.

Ft. Myer, Va.—Bids are wanted Jan. 10 for constructing macadam road, as advertised in The Engineering Record.

Canton, O.—Bids are wanted Dec. 29 for $19,100 street improvement bonds. C. C. Loyd, City Clk.

Terre Haute, Ind.—Bids are wanted Dec. 29 for macadamizing 4 streets. Robt. H. Sparks, City Engr.

Cincinnati, O.—Bids are wanted by the Bd. of Pub. Service until Dec. 19 for improving a portion of Woodlawn Ave. by grading, curbing and macadamizing; also for improving a portion of Hand Alley, by grading, setting curbs, and paving the roadway with brick. Geo. F. Holmes, Clk.

Bids will be received by the Bd. of Pub. Service until Dec. 22 for improving a portion of Bassett Road by grading, setting curbs, flagging and macadamizing the roadway. Bids will also be received until Jan. 6 for improving a portion of Front St. by grading, setting curbs, and paving the roadway with granite. Geo. F. Holmes, Clk.

Toledo, O.—Bids are wanted Jan. 5 for furnishing material and improving a portion of Willow Ave., by paving with block on a 6-in. concrete or 8-in. sand foundation, or with asphalt block, on a 6-in. bank gravel or broken stone foundation. Chas. H. Nauts, City Clk.

The lowest bid opened Dec. 1 for paving on Detroit Ave. is reported to have been from Jas. Sheehan at $1.52 for Athens block for concrete foundation or $1.10 with sand foundation; grading, 17 cts.; the contract calls for 8,505 yds. of paving and 2,500 cu. yds. of grading.

Bloomington, Ill.—Brick pavement and sewers will be constructed on Seminary Ave.

St. Paul, Minn.—The Bd. of Pub. Wks. has awarded to W. J. Preston the contract for macadamizing a portion of Concord St., for $17,313.

Findlay, O.—A petition is being circulated for the paving of West Crawford St. with brick.

Chicago, Ill.—The Bd. of Local Improv. has ordered portions of the following streets paved with asphalt: Brigham St., $16,500; Clay St., $13,000; Hastings St., $49,000; West Ohio St., $32,500; Ballou St., $28,000; Elk Grove St., $13,000; West Huron St., $17,000; Keenon St., $15,500; Locust St., $21,500; Wisconsin St., $14,500; Belden St., $77,000; Walnut St., $47,000; Morgan St., $6,500. Streets ordered paved with brick were Center Ave., $11,500, and W. 67th St., $13,000.

Manistee, Mich.—Col. E. W. Muenscher has just completed the survey of a branch of the Manistee County Road from a point on the main line 4 miles out from Manistee to Portage Lake and Onekama, a distance of 7 miles. The grading and claying of this line will be put under contract next spring, and possibly a considerable amount of macadamizing on the main line.

Milwaukee, Wis.—Local press reports state that there are 40 miles of cedar block pavement left in this city, a large portion of which is in such a condition that new pavement will be necessary soon.

New Castle, Ind.—A petition has been signed by South Main St. residents to pave that thoroughfare early in the spring; brick will probably be the material used.

Delphi, Ind.—Carroll Co. Comrs. are reported to have awarded the contract, for 32 miles of free gravel roads in Burlington and Democrat townships, to Hillis & Co., of Cass County, for $53,000.

Saginaw, Mich.—City Engr. Roberts estimates that the street paving work already proposed for next year would cost fully $200,000, while the amount available for the year is said to be only about $30,000; the only solution is said to be a charter amendment. For the 17 streets which it is proposed to pave, bituminous macadam and brick, with possibly some asphalt, will be used.

Columbus, O.—The contract for paving Pearl alley has been awarded to Baldwin Bros. & Graham at a cost of $8,588, Bolen Blk. to be used.

Washington, Ia.—The City Council has passed a resolution to pave with brick the square and 1 block each way and the 4 alleys through the blocks abutting on the public square.

Madison, Wis.—Bids are wanted Jan. 3 for furnishing material and grading, curbing and paving with asphalt on a portion of Mifflin St. O. S. Norsman, City Clk.

Wellsville, O.—Bids are wanted Dec. 27 for furnishing material and laying about 70,000 sq. yds. of pavement in this city; bids on various kinds of material will be received. O. K. Buckhout, Secy.

Battle Creek, Mich.—The City Engineer's final estimate of $19,321 for the cost of paving Muskegon Ave., $8,662 for Third St. and $4,053 for Grand Ave. has been referred to the Street Com.

Laporte, Ind.—The County Comrs. have awarded the contract for completion of unfinished macadam roads in Laporte Co. to Ralph H. Bertsch & Co., of Alexandria, for $38,450.

La Crosse, Wis.—City Engr. Frank Powell estimates the cost of paving, for which contracts are about to be let, at $9,882 for north side macadam, $94,270 for south side macadam, and the total for brick paving, $60,278.

Oklahoma City, Okla. Ter.—The property owners on East Reno St. are circulating a petition for the paving of that street with asphalt.

St. Joseph, Mo.—Local press reports state that King Hill Ave. is to be paved before spring, making a good thoroughfare between this city and South St. Joseph.

Helena, Ark.—A resolution has been introduced in the City Council directing the City Engr. to prepare estimates of the cost of paving Cherry St. with brick and asphalt.

Louisville, Ky.—The Bd. of Pub. Wks. has awarded to Henry L. Kremer the contract for paving 4 alleys with vitrified block at $1.27 per sq. yd., total about $5,700.

Y.—Bids are wanted Dec. 19 for furnishing and delivering 12,200 tons of broken stone and screenings of trap rock of Staten Island granite, and 1,500 tons of limestone screenings, also 1,500 tons of ⅜-in. "Tomkins Cove" (or similar) limestone screenings. Geo. Cromwell, Boro. Pres., New Brighton.

Brooklyn, N. Y.—The only bid received Dec. 10 by J. Edw. Swanstrom, Boro. Pres., for 42,000 cu. yds. of dredging in Gowanus Canal and elsewhere, was from the Morris & Cummings Dredging Co., 17 State St., N. Y., at 73 cts. per cu. yd. Work to be readvertised.

Bolivar, N. Y.—The United Pipe Line Co., at its annual meeting, held recently in Wellsville, voted to increase its capital stock from $100,000 to $150,000 for the purpose of extending the line and making improvements. A. L. Shaner and Jas. B. Wakeman, of Bolivar, were elected directors.

Terre Haute, Ind.—The County Comrs. have granted the petition of the Sugar Creek Levee Asso. to issue $25,000 bonds with which to build a levee west of the city and protect 1,500 acres from overflows of Wabash River.

New Orleans, La.—Coleman, Malochée & Villeré, Engrs. of the Bd. of Comrs., Port of New Orleans, write that the contract for building a 900-ft. wharf at Julia St., has been awarded to J. H. Gardner Const. Co., of New Orleans, for $22,032.

St. Irenee, Que.—Bids will be received Dec. 26 by Fred. Gelinas, Secy. Dept. of Pub. Wks., at Ottawa, Ont., for constructing an extension to the wharf at St. Irenee.

Montreal, Que.—The Road Com. has agreed to pay two-thirds of the cost of a $21,000 tunnel or subway on Forsyth St., on the understanding that the Montreal Terminal will pay the other third.

NEW INDUSTRIAL PLANTS.

The Hughes Bros. Mfg. Co., Dallas, Tex., contemplates erecting a 5-story and basement, 80x121-ft. addition of mill construction. It has not been decided whether or not the power plant will be increased.

The Conanicut Mills, Fall River, Mass., are erecting a 2-story building which will have about 21,000 sq. ft. floor space. A power plant of about 250 H.-P. will be installed.

The Sheffield Car Co., Three Rivers, Mich., expects to erect immediately a 90x250-ft. foundry to be equipped with a 40-ft. traveling crane.

S. G. Hunter, Atlantic, Ia., will erect a 44x108-ft. foundry to be equipped with electric motors.

E. W. Church, Covington, Va., will quarry from 200 to 400 tons of limestone daily for fluxing, burn lime quite extensively, and erect brick kilns. He is in the market for brick machinery, rock drills, boilers, iron jackets and fire brick, and wants estimates and plans for 200 and 300-bu. lime kilns with iron ¼-in. thick.

Wm. P. Davis, Equitable Bldg., Atlanta, Ga., is interested in the slate business at Rockmart, Ga., and will organize a company to operate on a large scale in the near future.

The Oregon, Ill., Foundry Co. will erect a 60x170-ft. foundry and 50x80-ft. machine shop, to have four stories. The plant will be operated electrically, power being purchased from a local power company. F. G. Jones is interested.

BUSINESS NOTES.

The Ball Engine Co., Erie, Pa., reports the following among recent orders: W. M. Buchanan, Odell, Ill., a 150-H.-P. direct-connected engine; C. C. Mengle, Jr., & Bros. Co., Louisville, Ky., a direct-connected unit; Magnus Metal Co., Chicago, a 150-H.-P. vertical and a 60-H.-P. horizontal engine.

The New York Continental Jewell Filtration Co. reports that it has closed a contract with the Maharaja of Mysore, India, through Capt. A. J. de Lotbiniere, Royal Engrs., English Army, who was sent from India to New York by his government for that purpose. The filter plant is to consist of four Jewell gravity filters, each 29 ft. in diameter, constructed of granite laid in Portland cement. There will be a masonry subsidence basin holding 400,000 Imperial gals. The capacity of the filter plant is to be 2,600,-600 U. S. gals. It will be erected early in the spring by one of the filter company's engineers, and is to be located at Bowringpet in the Kolar gold fields near Bangalore, Mysore. E. B. Weston, M. Am. Soc. C. E., consulting engineer. The company has also just received an order from Jones & Laughlins, Pittsburg, Pa., for a filter plant to be used in their South Side steel mill; and from Geo. Watkins & Co., Philadelphia, for a battery of filters to be used in their boiler service.

The Philadelphia Pneumatic Tool Co. has just completed the equipment of the new navy yard at Kiel, Germany, with Keller pneumatic tools. The company also reports an increasing trade on the Pacific coast; O. A. Berger, the company's representative in San Francisco, has just visited the home office, bringing with him some large orders from shipyards, steel works, etc., on the Pacific Coast.

The Crocker-Wheeler Co., Ampere, N. J., manufacturer of electrical machinery, has included among its shipments of engine type generators for the month of November one 400-Kw. for the Stephen Girard Bldg., Philadelphia; one 100-Kw. and one 125-Kw. for the Missouri Pacific Ry., St. Louis, Mo.; two 150-Kw. for the Penna. Malleable Co., McKees Rocks, Pa.; one 200-Kw. for J. L. Mitchell, Philadelphia; two 50-Kw. for the Liveright & Greenwald Bldg., Philadelphia; two 100-Kw. for the McClintic-Marshall Construction Co., Pottstown, Pa.; one 300-Kw. for the Grand Crossing Tack Co., Chicago; one 400-Kw. for the Lake Construction Co., Erie Co., Pa.; one 250-Kw. for the Wilmington, Del., City Elec. Co.; one 225-Kw. for the Pine Bluff, Ark., & Western Ry.; two 150-Kw., one 200-Kw. and one 75-Kw. for the Woodward & Lothrop Bldg., Washington, D. C. The company reports that its new mill building is now being occupied, enlarging the floor space by 60,000 sq. ft. and giving increased facilities for prompt deliveries on large orders.

The Cleveland Cliffs Iron Co. is about to install an electric power distribution system for operating mixers and blowers in its Gladstone, Mich., plant, and has recently purchased from the Westinghouse Electric & Mfg. Co. two 75-Kw., direct-current generators and eight 10-H.-P. direct-current motors. The Pioneer Iron Works, of Marquette, Mich., owned by the Cleveland Cliffs Co., will also be equipped with electrical apparatus for the operation of mixers and blowers, and the apparatus recently purchased from the Westinghouse Electric & Mfg. Co. for this plant includes ten 10-H.-P. direct-current motors and two 150-Kw., engine-type generators to be direct connected to two Westinghouse compound condensing engines. The company has also ordered a Baldwin-Westinghouse electric locomotive to be used for shifting cars in its yards.

High-Pressure Steam Piping.......................... 589
Electric Heating and Lighting in the Carnegie Residence, New York. (Illustrated).......... 590
The Rowe System of Burning Pulverized Coal. (Illustrated) 592
The Water Supply of King's Lynn, England..... 593

The Engineering Record is published every Saturday at 114 Liberty Street, New York. Its opinions on technical subjects are either prepared or revised by specialists.

Subscriptions are received and single copies supplied by the International News Company, Breams Building, Chancery Lane, London.

The subscription rate is $5 a year for the United States, Canada and Mexico, and $6 for other countries in the Postal Union. Remittances should be made by check, New York draft or money order in favor of The Engineering Record. No responsibility is assumed for payments made otherwise, except those for subscriptions to the International News Company.

The offices of The Engineering Record have been removed to the sixth floor of the Engineering Building, No. 114 Liberty Street, New York.

The Use of Oil Fuel.

The recent annual report of the Bureau of Steam Engineering, of which Rear Admiral George W. Melville is the chief, contains some valuable data bearing upon the relative evaporative efficiency of Texas oil and certain well known steam coals. A series of tests with each fuel was conducted in which the conditions as to rate of combustion and evaporation were varied through a wide range. The tests were made upon the same boiler, thus rendering it possible to make a fair comparison of the results. They were conducted by a board of engineers appointed by the Navy Department, and the principal data and results are given upon another page of this issue. While the oil tests were made with the idea of securing data bearing upon the use of oil as a fuel in marine service the results and conclusions drawn from the entire series should be of no little interest to those designing and operating boilers for stationary plants.

In discussing the mechanical problems involved in the use of oil fuel Admiral Melville points out that since the time inventors realized that the efficient, economical and rapid burning of liquid fuel was greatly dependent upon the success secured in atomizing the oil there was rapid improvement. It was only a few years ago, he states, that the oil was simply thrown into the furnace with an injector, and the evaporation was dependent to a great extent on the amount of incandescent surface that could be secured to ignite the fuel. There are many burners, the report states, which can atomize the oil quite satisfactorily. The heating of the oil, also the heating of the air required for combustion, must be provided for and the latter requisite should be impressed upon all contemplating the use of liquid fuel as a combustible. Until recently, Admiral Melville writes, there have been no records to show that a boiler could be forced with oil fuel to the same extent as with coal, but the experiments of the liquid fuel board have shown that this is now possible, and that the greatest evaporation per square foot of heating surface secured with coal can be greatly exceeded by an oil fuel installation of modern design where provision is made for atomizing the combustible and heating the air and oil. In one of the tests an evaporation of 16.7 pounds of water from and at 212 degrees F. per square of heating surface per hour was attained, so that the boiler operated upon a basis of about 2 square feet of heating surface per horse power instead of 12 square feet, a common standard.

Of course in stationary practice the most important question involved in the use of oil fuel, after it has been shown that mechanical objections have been overcome, is the commercial one. Oil has been used as fuel for a number of years in a spasmodic way, but it has been the experience of most plants that oil cannot compete with coal. Admiral Melville states that only at certain California ports and at ports in the Gulf of Mexico oil costs less than coal. This is attributed to the expense of transporting the oil, but it is believed that this disadvantage ought to be soon removed. It is pointed out that while oil may be put on a tank steamer at certain ports like Cape Sabine its commercial value will be determined by the cost of delivery at commercial and maritime centers. The expense of fitting up the few tank steamers conveying oil from Cape Sabine to the North Atlantic seaports has been very heavy, due to the fact that unexpected difficulties developed in making the installations. It is believed that when a large fleet of tank steamers is available and when terminal storage facilities are provided there will be a material decrease in the price of oil in the leading cities on the coast.

As regards the danger from oil fuel it is pointed out that extreme precaution will have to be taken, and the recent explosion of oil upon a ship at San Francisco, in which a number of persons were reported to have been killed, emphasized its need. However, the danger may be overcome by proper care and by experience in its use and this does not in any way detract from the value of the work done by the oil fuel board. Further experiments are contemplated by the Navy Department, and it is to be hoped that their disinterested and valuable work may be continued, for the subject is of no little importance to industrial as well as to naval engineers.

The Convention of the American Institute of Architects.

The thirty-sixth annual convention of the American Institute of Architects was held in Washington on Thursday, Friday and Saturday of last week, in the New Willard Hotel. The first session was opened with an address of welcome by Colonel John Biddle, U. S. A., engineer commissioner of the District of Columbia, and was followed by a short address by the Institute's president, Mr. Charles F. McKim. The remainder of the morning session was devoted to reports by various officers and committees. In the afternoon, following the appointment of several committees, papers were read on the "Improvement of Washington," by Messrs. Daniel H. Burnham, Frederick Law Olmsted, Jr., and Charles Moore.

It has long been realized by those competent to judge that Washington cannot be favorably compared, in point of beauty, with the capitals of the larger foreign countries. The subject of the improvement of our national capital has been strongly urged by many leading architects and the admirable work of the Institute along this line deserves acknowledgment. As a step in the right direction, it is a source of gratification to note that last Monday the House passed the Senate bill authorizing the erection of the $4,000,000 union railway station in Washington. Thursday evening the members assembled in the Congressional Library and viewed drawings and models submitted by the Park Commission, Messrs. D. H. Burnham, C. F. McKim, Augustus St. Gaudens and F. L. Olmsted, Jr. An explanation of the proposed plans for the improvement of Washington's park system was made by one of the members of the commission.

The principal feature of general interest in the Friday morning meeting was the paper by Capt. John Stephen Sewell, Corps of Engineers, U. S. A., on "The Relations of the Architect and the Engineer." Capt. Sewell, as an engineer, was closely associated with the architect in building the new government printing office, consequently his views had the weight of a personal experience. Among others, two points were particularly emphasized: the advisability of retaining a government engineer on all government buildings, rather than allowing the architect to select an outside engineer; and the desirability of having the work on government buildings entirely in the charge of a construction bureau, which could control all disbursements and secure the best possible co-operation among the architect, engineer and contractor. A paper by Mr. J. L. Smithmeyer on "The Development of Architecture" was then read by Mr. George O. Totten, Jr.

The "Development of Municipal Improvement" was the general topic considered during the afternoon session, December 12. Mr. W. B. de las Casas read a paper on "The Organization for Municipal Improvements," the particular work treated being the Boston park system, of which he has had charge as chairman of the Metropolitan Park Commission. Under the subject "The Modern City," Mr. Albert Kelsey showed in what ways foreign city work is ahead of American, and urged the need of modern ideas along original lines in our architecture. Mr. Kelsey is in charge of the park improvement work in Philadelphia. A third paper, written by Mr. Owen Fleming, the secretary of the council of improvement of London, England, was read by Mr. Glenn Brown. It dealt with the improvements put into effect in that city.

The Saturday meeting was late in opening, as the earlier part of the morning was spent in visiting the White House. Mr. McKim, to whom the work of remodeling the White House was unreservedly committed, guided the delegation, and its members declared themselves greatly pleased with the results accomplished. The morning meeting closed the balloting for the election of officers. Last year's board of officers was re-elected, as mentioned in the "personal" column of this issue, together with three elections to honorary membership. Cleveland was chosen as the place for the next convention, with St. Louis as the probable convening point for the year following. A paper by Capt. Charles D. Sigsbee on certain improvements in Washington was read by Mr. Arthur Totten. Capt. Sigsbee suggests the construction of a permanent reviewing stand on Lafayette Square in front of the White House, the stand to be made of marble and highly ornamental. The committee in charge of the subscription for the purchase of the historic Octagon house in Washington as a permanent institute headquarters reported that $17,000 was in hand. After the purchase money, $30,000, is raised, it is proposed to raise a sum of $250,000 for the establishment of a benefit fund.

The Muscoot Dam in the Croton Valley, New York.

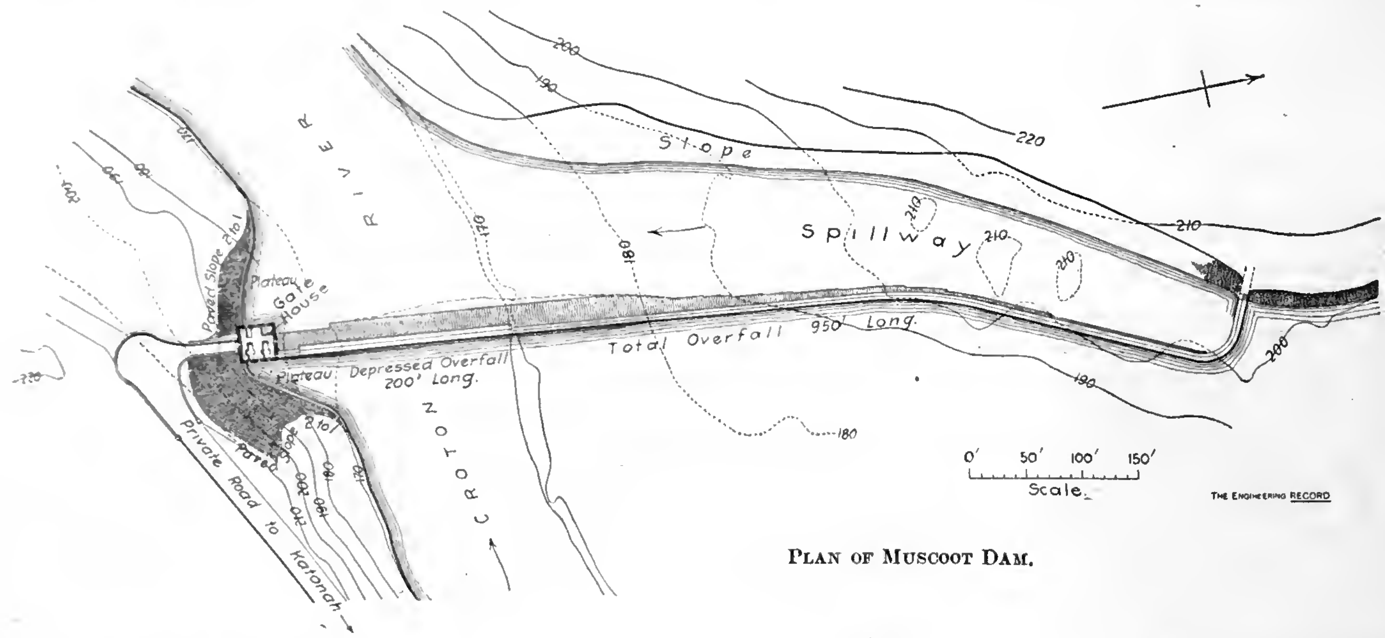
The Muscoot dam is a masonry structure now under construction in the Croton valley, being a part of the system of improvements and extensions in progress for the water-works of the city of New York. The new Croton dam (see The Engineering Record of August 16) will, when put in use, impound a body of water about 19 2/3 miles long, and the Muscoot dam will be located at about the middle of this lake, being about 5¼ miles above the old Croton dam. The lowest part of the spillway of the Muscoot dam will be 200 feet long and at the same level as the lowest part of the spillway of the new Croton dam, or 196 feet above sea level. Stop planks will be used when desired to raise the level to that of the rest of the structure, 4 feet higher, giving under these conditions a spillway 950 feet long. The Aqueduct Commissioners decided to construct the dam at this point so that when the large lake shall be drawn down below the level of the spillway crest of the new Croton dam, the bottom of some of the shallower portions toward the upper end of the lake will not be partially or wholly exposed.

For a very short section the Muscoot dam will be 60 to 70 feet high from the bottom of the foundation. From the old bed of the river to the top of the flashboards on the finished dam the height will be about 35 feet. For about 450 feet at the north end, it is only from 3 to 13 feet in total height, having been extended to a considerably greater length than was otherwise necessary in order to gain a long crest for the spillway. In fact the rock bottom in several places at the north end was higher than the crest of the dam. A channel below the dam, excavated largely in the rock, will carry the water overflowing from this end of the dam down to the main channel of the river.

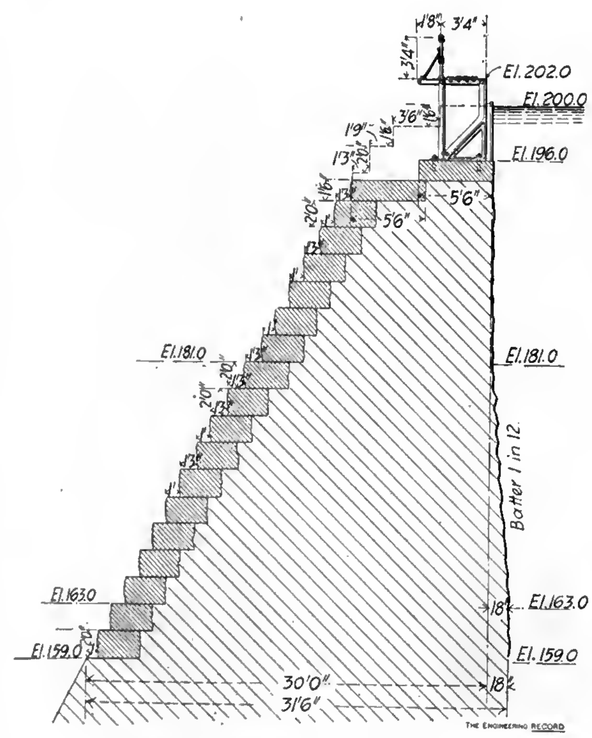
The bed rock was comparatively near the surface throughout almost the whole length of the dam. It was deepest directly below the bed of the river, there being at that point a V-shaped depression in the rock, making a deep excavation necessary for a short section. On the south bank of the river, the rock as a rule is not so near the surface.

The accompanying section shows the general character of the work. The dam is founded entirely on the bed rock. The downstream face is stepped off at the rate of about one horizontal to two vertical, and the upstream face will be vertical to 19 feet below the top, and below this to elevation 163 it will have a batter of one inch to a foot, being again vertical below that elevation. The main body of the dam and overfall, the gate chamber and retaining walls will be of rubble masonry laid in 1 to 3 Portland cement mortar. In the long spillway, however, and such other places as the engineer may designate, the masonry will be laid in 1 to 2 Rosendale cement mortar. No grouting is allowed. Stones of various sizes are used and regular coursing avoided, in order to obtain good vertical bonding as well as horizontal. In places where the masonry is thickest, a considerable proportion of large stones is used. In some cases the vertical joints, where not less than 6 inches wide, are filled with a concrete consisting of one part cement to three of small stone or gravel, this concrete being thoroughly rammed.

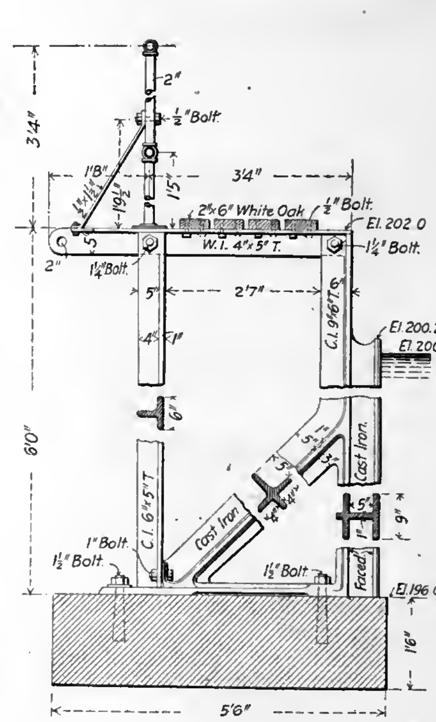
The top course of the dam is to be of dimension stone masonry. The large blocks used for the steps on the downstream face are carefully selected in order that they may be especially hard and compact, so as to withstand the shock of water and ice falling over them. Below the dam, at the depressed overfall, for 50 or 60 feet from the toe of the dam, there will be a protective apron of piling filled in with large stones measuring a cubic yard or more in volume.



PLAN OF MUSCOOT DAM.



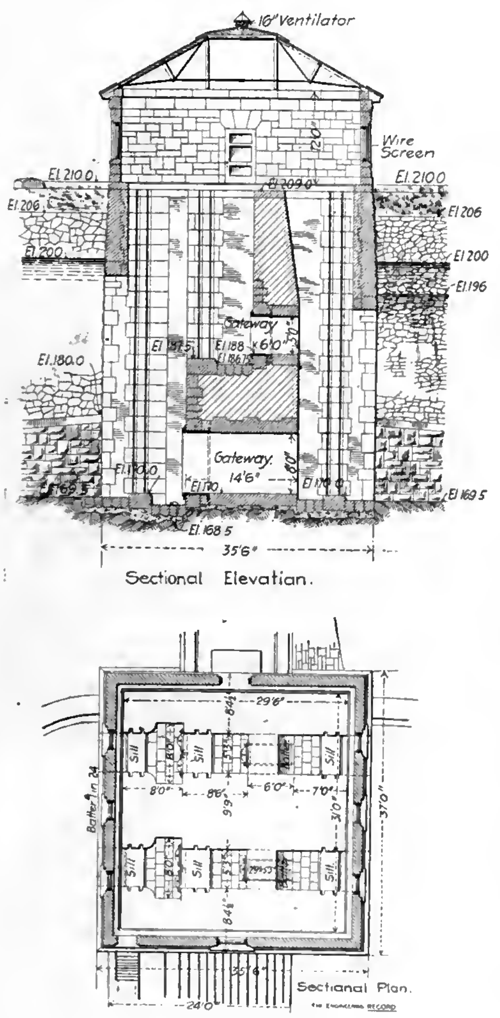
SECTION AT DEPRESSED SPILLWAY.



FLASH-BOARD STANDARD.

Along the 200 feet of depressed spillway, cast-iron frames will be secured every 8 feet to the top course of the masonry by anchor bolts, and in the grooves of these frames can be placed stop-planks or flashboards, in order to raise the water level to elevation 200. A foot bridge from which to operate these flashboards will extend from the gate house to the end of the depressed overfall. The bracket standards and the parts for supporting the foot bridge are of cast-iron; other metal parts are of steel.

At the south end of the dam, where the gate house will be located, excavation was necessary for a plateau or level area at elevation 169.5. There will be a low, submerged retaining wall at the edge of this area, and a paved slope will extend above this wall on both sides of the dam up to elevation 206. The excavation for the level area was planned to extend well into the solid rock in order to give a good foundation for the gate house. The gate house will be built entirely of masonry, with two arched openings for inlets, 5 feet 3 inches wide and extending from the plateau level to 2 feet below the surface of the full reservoir. Just beyond these inlets there is a double set of vertical grooves 5 inches wide and 6 inches deep, for stop planks, and beyond these grooves on either side of the gate house is a main gateway opening 8 feet high and 5 feet 3 inches wide, divided for two 2x8-foot sluice gates, the elevation of the bottom of the opening being 170. Above these two main gateways, at elevation 188, are two others 2 feet 9 inches wide, with single sluice gate 2x8 feet. Here there are also double sets of grooves for stop planks in front of the inlets. There will be still another series of stop planks between the ends of the gateways and the arched outlets. The outlets are 5 feet 3 inches wide and about 24 feet in height, the inside crowns of the arches being about 2 feet below the level of the depressed overfall. The floor of the gate house is at elevation 210. The three sets of stop plank grooves on either side of the gate house were provided in order to give complete control of the sluice gates. If at any time it is desired to gain access to the gates or the bottoms of the gate chambers, the planks will be put in and the space between the two parts of each



GATE CHAMBER.

set rammed full of clay. The chamber can then be pumped out.

The preliminary estimates for this work, by which the bids of the contractors were compared, included the following items: 105,000 cubic yards earth excavation, 4,000 cubic yards earth excavation in vertical trenches, 25,000 cubic yards rock excavation, 1,500 cubic yards dredging in river, 250,000 feet, B. M., of timber work placed and fastened, 7,500 linear feet of piles, 15,000 cubic yards rubble stone masonry laid in 1:2 American cement mortar, 5,000 cubic yards rubble stone masonry laid in 1:3 Portland cement mortar, 5,000 cubic yards riprap, 7,000 square feet fine hammered face dressing, and 5,000 square feet rough-pointed face dressing. Mr. W. R. Hill is chief engineer of the Aqueduct Commission, under whose supervision the work is being carried on. Mr. E. Wegmann is the division engineer, and Mr. C. E. Benedict is the assistant directly in charge of construction. The contractors are Messrs. Williams & Gerstle, of New York, and the contract price for the total work was about $209,000.

Report of Irrigation Investigations.

Abstracted from Annual Report of the Department of Agriculture.

The portion of the report of Mr. James Wilson, the Secretary of Agriculture, which deals with irrigation describes what the department has been doing during the past year and incidentally brings out many facts of general interest. Interest in these investigations, which are a part of the work of the Office of Experiment Stations, is constantly increasing and has been stimulated during the past year by the growing desire of the arid states for laws and conditions which will secure the largest and best use of the water supply, and in the humid region by the drought which prevailed throughout the middle West in 1901 and in the South during the present year. As a result, the requests for information and advice have been more numerous than ever before, and it was only through the increased appropriation made by the last congress that those in charge of the investigation have been able to comply with the demands made upon them.

Referring to the need of better irrigation laws, the secretary says that no branch of the department's irrigation work has received more cordial recognition than its studies of legal and sociological questions. A number of the arid states are cooperating with the department in these studies and two have made special appropriations to extend them. The question as to how much the water of western rivers has already been appropriated under state laws, the nature of the rights which have been acquired, the conflict which exists between riparian rights and the rights acquired under the doctrine of appropriation, are some of the problems which confront irrigators in these states. A settlement of the rights which have become vested is needed to show how much water remains for future appropriators and to relieve farmers under existing ditches from anxiety and give to a state a safe foundation for future development. To the litigation over water rights within states there has recently been added important suits over interstate rights, the one of Kansas against Colorado being the most conspicuous. The law providing for the department's investigations provides first of all for an investigation and report on the laws affecting irrigation and the rights of riparian proprietors. Under this, an investigation of interstate rights is now going on, the results of which will be watched with much interest.

The report of the secretary brings out the fact that drainage is becoming an important problem in the older irrigated districts. Two drainage surveys were carried on during the past year; one in the valley of Kings River in California, under the direction of Prof. O. V. P. Stout, and another in Colorado which was carried on by Mr. C. G. Elliott, agent and expert, under a cooperative arrangement between the state engineer's office of Colorado and the Office of Experiment Stations of the Department. The owners of lands which have become swamped by too much water will be encouraged by the results thus far secured, the secretary reporting that they show that it is not only possible to remove the surplus water and restore large areas of land to cultivation, but that the water which comes from these drains can be used for the irrigation of other lands.

The report further shows that much interest is being given to irrigation in the humid states, especially in the south where the irrigation of rice has proven exceedingly profitable, and where important experiments are being carried on to determine the value of irrigation as an aid to market gardening. The fact that the department has in its employ a number of irrigation engineers who have had wide experience in the West has resulted in a saving of large sums of money to those who were putting in pumping plants. This has been done by correcting a tendency to put in pumps of too small capacity to be of any real service.

He also calls attention to the changes in farm life and farm work which have come about through the invention of machinery and its extensive use by American farmers. The United States is the greatest manufacturer and user of farm machinery in the world, and the changes which have come about through their invention have made almost as radical a revolution in farming operations as has been wrought by the substitution of machinery for hand labor in manufacturing. Among the complex machines which the farmer has to operate to-day are combined harvesters and threshers, traction engines, automobiles, power machines for harvesting corn, for shucking the ears and shredding the stalks, and recently electric dynamos have been added to the agencies employed to do farm work. These facts, in connection with the increasing demand for more efficient labor-saving tools, the growing scarcity of farm labor, and the organization in foreign countries of institutions for the systematic study and improvement of farm machinery, make it important, in the opinion of the secretary, that we should not longer neglect this field of inquiry, and provision for carrying this out in connection with the irrigation investigations is recommended in the secretary's report. In his estimates submitted to Congress, the Secretary asks for an appropriation of $75,000 to continue the investigations in irrigation and agricultural engineering.

The San Jose Scale has been made the subject of a very searching investigation by the Division of Entomology, Department of Agriculture, the results of which are presented in the annual report of Secretary Wilson. Explorations in Japan and China have established very clearly that its original home was in the latter country. It was found in scattering numbers everywhere, just as one would expect in the native home of a pest of this sort where it is normally kept in check by natural enemies. A very interesting fact in connection with this discovery was the finding in this same region of a ladybird which preys on it naturally and seems to be the principal agent in preventing its often becoming very abundant and injurious. This ladybird (*Chilocorus similis*), a European and Asiatic species, in China feeds naturally on the San Jose scale and related forms, as also on the white peach scale, a very troublesome pest, which has recently gained foothold in our Eastern and Southern States. Several shipments of this beetle were made by Mr. Marlatt, first assistant entomologist, some from Japan and some from China. From the two surviving individuals more than 2,000 beetles and larvæ are now on scale-covered trees on the Department grounds. In addition to these, shipments of some thousand beetles have been already made to other points in the East, a number of experiment station entomologists having expressed a desire to assist in the work of propagating, distributing, and establishing this useful ladybird. This importation promises most flattering results at present. It is, however, still an experiment, and what the ultimate benefit will be can only be determined after a two or three years' test.

The Revised Plans for the Superstructure of the Blackwell's Island Bridge, New York.

The commission of engineers appointed November 3 by Mayor Low to investigate the proposed modifications of the plans for the Blackwell's Island bridge has submitted its report, giving a very clear comparison in all essential points of the original plan and that recently proposed by Commissioner Lindenthal. There is also appended a third plan, in which the commission, Messrs. William H. Burr, Henry W. Hodge, and Palmer C. Ricketts, has endeavored to combine the best features of the other two.

In brief, the original plan called for a cross-section in which there would be two middle roadways, each 20 feet wide in the clear, two double-track street car platforms 22 feet wide in the clear, one platform next to each main truss, and two cantilever sidewalks 10 feet wide outside the trusses. About 25 feet above the roadway level there were to be two single lines of elevated railway track, each centered over the posts separating the roadway and street car platforms. The total width of this plan is 120 feet.

The plan proposed by Commissioner Lindenthal called for a total width of 80 feet, with a clear space between main trusses of 44 feet. The roadway was to occupy the center of this, and there were to be two trolley tracks just inside the main trusses open also to wagon traffic, and two outside, the outside ones being supported on cantilever arms, 15 feet long. The reduction in width was to be gained by bringing the two tracks for the elevated trains together in the center of the upper deck, which was to be 15 feet clear above the lower one, and placing the two promenades, each 11 feet wide, on the upper deck, one on each side of the elevated tracks.

The plan proposed by Messrs. Burr, Hodge and Ricketts is practically a widening of that of Commissioner Lindenthal by inserting 11 feet of clear space into the center of the section, and making a complete separation between the central roadway (widened in this way to 36 feet in the clear) and the trolley tracks on each side. According to this plan there will be a clear width of 56 feet between the two main trusses and two trolley lines on the outside supported on cantilevers. The upper deck will be arranged with the two 11-foot promenades inside the main trusses and adjacent to them; and the two lines of elevated railway are to be placed as close as possible to the promenades. This plan gives a total width of 91 feet, which it is thought will be more in keeping with the piers, which were of course designed for the full width of 120 feet. The report of the commission concludes as follows:

"We further recommend that a solid floor on buckle plates be used on the lower deck between the main trusses, and that the lightest practicable continuous fireproof flooring be used on the sidewalks, the two elevated railway tracks and the spaces between the overhanging and the adjacent trolley tracks. The remaining portions of the overhanging trolley tracks should have an open fireproof floor as light as practicable. The central space between the elevated railway tracks should be entirely open to admit light and air to the roadway below. It is the opinion of the commission that this material decrease in the dead weight of the floors will fully compensate for the small increase in weight resulting from the increased separation of the trusses without increasing the cost of the structure. It is further the judgment of this commission that the capacity afforded by this plan is not beyond reasonable provision for the future requirements of the locality served by the bridge."

Loading Tests of Ransome Concrete-Steel Floor Construction.

Comparative tests of full size floor panels of different spans and construction were made by the Turner Construction Company, New York, September 23 and 24, for the Building Department of the Borough of Richmond, New York City. They were intended to demonstrate the actual relation of theory to practice in commercial construction, and to verify for the officials of the department the strength and rigidity of the Ransome system of cold twisted steel reinforcement which is being extensively used in new buildings now being erected at New Brighton for J. B. King & Company's cement and plaster mills. The Turner Construction Company is the licensed agent for the Ransome system, and is the contractor for the new buildings, the roofs of which are also to be of the same style of construction as the floor panels tested.

Four floor panels were constructed on August 20, two of 9 feet 2 inches clear span and two of 14 feet 6 inches clear span, as shown in the illustrations. The smaller span was designed for a distributed live load of 600 pounds per square foot and the larger span for roof construction with a specified distributed live load of 50 pounds per square foot. One panel of each span was constructed of gravel concrete consisting of 1 part Lehigh Portland cement, 2 parts clean, sharp sand and 4 parts clean Long Island gravel running in size from ¼ to ¾ inch diameter. The other two panels were constructed of the same proportions of cement and sand with 4 parts ¾ inch screened trap rock. These panels were constructed in duplicate to compare the strength of gravel and trap rock concrete with the same metal reinforcement. The concrete was mixed by hand with sufficient water to flush readily to the surface in tamping, and would be termed "wet" mixtures.

The cement was of very good quality and was tested by Dr. Charles F. McKenna, with the following results: Tensile strength of briquettes 7 days old, in pounds per square inch, neat, 624; 3:1 mortar, 250. Four 6-inch cubes were made from the concrete, and when 48 days old, were tested at Columbia University. One of the gravel cubes was slightly cracked across one corner. The ultimate crushing strength of the gravel concrete cubes was 2,545 pounds and 2,923 pounds per square inch, and of the trap rock concrete cubes 3,280 pounds and 3,286 pounds per square inch. The steel reinforcement consisted of square bars of mild steel twisted cold. Tension tests were made on the plain and twisted bars by Professor Woolson, of Columbia University, and gave the following results in pounds per square inch:

Size and Condition.	Elastic Limit.	Ultimate Strength.
¼ inch, plain	46,170	57,800
¼ inch, twisted	62,350	86,700
¾ inch, plain	34,840	59,200
¾ inch, twisted	56,720	85,240
⅞ inch, plain	39,700	62,100
⅞ inch, twisted	56,150	84,730

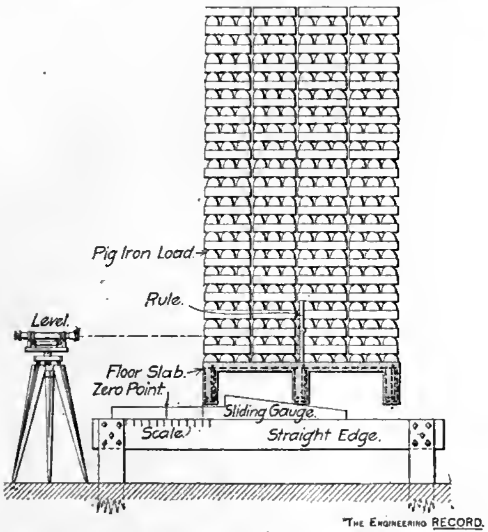
LOADING TEST SLAB.

CONSTRUCTION OF TEST SLAB.

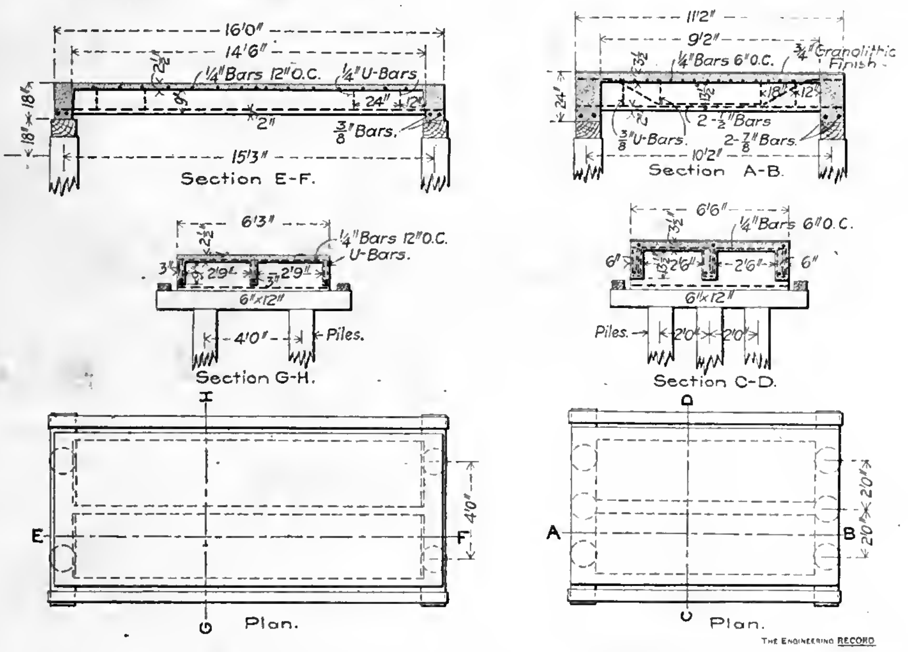
On each panel two 12x12-inch spruce timbers were laid side by side over the center beam to receive and concentrate the load on a strip 2 feet wide, across the full length of the span. The pig iron was piled centrally on these timbers, and as the height of the pile increased the pigs were carried up an inclined platform and carefully deposited on top, as shown in the view. An engineer's level was set up near the panel under test, and with it readings were taken on a rule held vertical on the middle of the center beam, in an opening left in the pig iron for that purpose. Readings were also taken on the top of the concrete over the supporting piles, and the differences of these and the center readings gave the true deflections corrected for any error due to the settlement of the piles or the compression of the timber under the heavy loads. The total displacements were also checked by readings taken on a beveled gauge which moved between a horizontal straight edge and the lower side of the center beam, as shown. A zero point was marked with the gauge touching the unloaded beam, and as the beam deflected the gauge was withdrawn to remain always just in contact with it, and the position of the zero point was read on a scale marked on the straight edge to correspond with 1/16-inch deflections of the beam. These divisions on the scale were so large that they could be accurately subdivided to read an eighth of a sixteenth.

The 9-foot 2-inch span of gravel concrete was the first section tested, and the maximum load reached was 110,218 pounds, or 4,007 pounds per square foot of panel area. This produced a center deflection of about 1/16 inch, and exhausted the supply of pig iron so that further loading of this panel was abandoned. The test demonstrated very satisfactorily the strength and rigidity of the construction, but could not be conveniently carried far enough to establish any theoretical deductions. When the load was removed the next day the beam was found in perfect condition. The corresponding span of stone concrete was not loaded.

The gravel concrete panel of 14½-foot span



MEASURING AND CHECKING CENTER DEFLECTION.



DETAILS OF LONG AND SHORT SPAN CONCRETE SLABS.

sustained a maximum load of 35,800 pounds, or 822 pounds per square foot of panel area, which produced a maximum center deflection of 1 5/16 inches. The deflections varied directly with the load, and the first sign of failure was noticed between loads of 28,652 pounds and 30,952 pounds, and consisted of fine vertical cracks at regular intervals near the center of the span. At 30,952 pounds diagonal shearing cracks appeared in the loaded beam about 2 feet from the supports. They increased in size and opened about ¼ inch at the maximum load. Cracks also occurred at the juncture of the 2½-inch floor slab with the supporting walls.

The maximum load on the 14½-foot stone-concrete panel was 32,784 pounds, or 753 pounds per square foot of panel area, producing a maximum center deflection of 1⅛ inch. The first signs of failure consisted of the fine vertical cracks occurring between loads 25,477 pounds and 28,756 pounds. Diagonal shearing cracks about 2 feet from each support began at this load and increased with the loading. This panel as well as the gravel panel was capable of carrying additional loads before absolute failure, although for all practical purposes failure had occurred. Deflection curves plotted for these two panels clearly indicate almost identical action. The strength of the gravel concrete panel ran a little higher than that of the trap rock panel. Both panels showed excellent elasticity and seemed to confirm the assumption that the theory of flexure may be applied to composite beams of the Ransome system. The failure occurred not by exceeding the ultimate strength of the steel in tension or the concrete in compression, but through shear. A careful examination was made of the twisted steel bars after the panels were unloaded and taken down, and they were apparently uninjured. They were also free from any signs of corrosion.

It was noted, however, that the adhesion between the steel and concrete was not so strong as sometimes supposed. The very large loads carried are explained in part by the ability of the floor slab to transmit a portion of the load to the outside beams. Nevertheless, the remarkable strength of this construction is attributed largely to the excellent union formed between the concrete and the grooves in the twisted bars; to the high elastic limit and ultimate strength of the steel and to its lowered ductility, permitting the two materials to act in unison. The contractors consider that the results of these tests encourage the application of the Ransome construction to a large field of heavy floor work.

The Commission of Engineers recently appointed to investigate the problems of water waste prevention and additional water supply for the city of New York have entered upon their duties and will hold a public hearing next Tuesday in connection with the subject of waste prevention. The commission is expected to make its final report by November, 1903, and to defray its expenses an appropriation of $100,000 has been made, of which $36,000 is for salaries of the commission. The Department of Water Supply, Gas and Electricity will co-operate in the studies. As previously announced, Wm. H. Burr, Rudolph Hering and John R. Freeman, Members Am. Soc. C. E., constitute this commission. Commissioner Robert G. Monroe and Mr. Nicholas S. Hill, chief engineer of the department, are active in furthering this work.

Compressive Resistance of Concrete-Steel and Hooped Concrete.

Probably no materials of construction are engrossing more of the attention of engineers in these passing days that the combination of concrete and steel. The fields of application for this compound material are continually widening and the varieties of the combination have not ceased to multiply. Among the most recent forms of union of steel with concrete for the reinforcement of the latter is the beton fretté or hooped concrete, of M. Considère. Experimental information on this subject, we are sure, will be of value to many readers. Simultaneously in "Le Génie Civil" and in the new periodical, "Beton and Eisen," published by Mr. Von Emperger, M. Considère prints under the above title the first comprehensive paper on his recent experiments on concrete-steel in compression. The high position of the author as an experimenter in the line of concrete-steel construction and the great value of these tests, which fairly bid to surpass his now famous bending tests, justify, in the opinion of The Engineering Record, an extended extract.

I. *Concrete Reinforced by Longitudinal Rods.*—The first idea which presented itself to engineers to increase the resistance of concrete in compression was to reinforce it, similarly to tension pieces, by rods laid longitudinally in the direction of the stress. For purposes of construction, to keep the rods better in place, the reinforcing rods were tied together by a network or a belt of smaller rods. Some engineers understood that these belts perform another important role, that they protect the longitudinal rods from premature flexure and retard the swelling of the concrete and, hence, its ultimate failure.

It will be seen below that by hooping or completely surrounding the concrete by steel rods a considerably higher resistance can be obtained, and it is evident that between this method, supplemented by the addition of longitudintal rods, on one side, and the method of reinforcing by longitudinal main rods tied together by belts of lighter material on the other side, there is an intermediate continuous series of methods of reinforcing. The conclusions reached by this study will enable us to foresee the effects of these complex combinations, but, before making the synthesis the influence of each element should be investigated separately. Concrete reinforced by longitudinal rods tied together by netting or belts of dimensions too small or spaced too far apart to exert noticeable influence on the resistance of the concrete will therefore be treated first.

It was admitted, up to the present time, that the different varieties of stone, mortars and concrete, when under compression, always fail by shearing along planes which are inclined to the direction of the stress. The recent experiments made in Germany by Foeppel and repeated by Mesnager at the laboratory of L'Ecole des Ponts et Chaussées have proved that this mode of failure is due to the friction exerted on the lower planes of the test specimens by the plates transmitting the pressure. And it has further been proved that by sufficiently reducing this friction by the introduction of a greased surface, the failure will take place along surfaces which will be parallel to the direction of the pressure. It is not clear how longitudinal reinforcing bars, which are parallel to the lines of rupture, could prevent the separation of the molecules and increase the resistance of the concrete, and it seems that the only effect of longitudinal reinforcing in compression members consists in adding the resistance of the steel to that of the concrete without strengthening the latter. Experience has shown that such is the case. The effects of the reinforcing bars are, however, complicated, for the reasons which follow.

As has been shown by the experiments which the author described in 1899, before the French Academy of Sciences, the tendency to shrink which concrete shows when setting in air causes in reinforced concrete inner stresses of great intensity: tension in the concrete and compression in the metal. Experiments made in 1902 at the laboratory of L'Ecole des Ponts et Chaussées, according to the programme laid out by the French commission on concrete-steel, have determined the effect due to shrinkage of large concrete-steel specimens of the most commonly employed mixture, 1,000 pounds of Portland cement to 45 cubic feet of 1-inch gravel and 22.5 cubic feet of sand, (1:3:6). Measurement of the variations in length of the reinforcing bars has shown that after three months the shrinking of the concrete had compressed the metal 6,540 pounds per square inch, in prisms 6.5 feet long of a section about 4x4 inches and reinforced near the edges by four iron wires ¼ inch in diameter. The compressive stress in the metal has reached 10,800 to 14,220 pounds per square inch in beams 13 feet long having a cross-section about 8x16 inches and reinforced near one of the smaller sides by four metal rods of ⅞-inch diameter placed 1.3 inches from the face. The latter specimens were prepared to be tested for bending.

It is superfluous to point out the importance of the above statement as to the magnitude of the interior stresses in members of the usual mixtures and dimensions similar to those met in practice. Neglecting this kind of stresses, some engineers have made grave mistakes in the interpretation of bending experiments and have established incorrect formulas and rules, especially on the subject of stresses in compression members. They have assumed that if a certain specimen has undergone a shortening, i, its reinforcing bars, which had a coefficient of elasticity, E, were compressed to a stress Ei, neglecting the addition which has to be made to the latter stress for the shrinking of the concrete, if it has set in air, and which usually exceeds it in amount. The above considerations are sufficient to compute the stresses in compression members as long as the elastic limit has not been surpassed, neither in the concrete nor in the metal; but this is only one side of the question.

Without entering into a discussion of the unit stresses which may be allowed for the various elements of concrete-steel structures, it is evident that the basis of any computation must be the knowledge of the stresses which are induced in these elements at the instant where, for the first time, there appears any danger for the one or the other of them. It is therefore important to know the stress caused by the reinforcing steel in a member in compression at the instant where it begins to fail by the crushing of the concrete, which takes place a long time before that of the steel.

A concrete of common quality can stand without crushing a reduction in length of 0.07 to 0.10 per cent. and sometimes more. Such a compression will cause a stress in the metal of 20,000 to 29,000 pounds per square inch, if the co-efficient of elasticity be 29,000,000 pounds. This stress, added to the previous stress of 7,000 to 14,000 pounds, gives a total of 27,000 to 43,000 pounds per square inch of the metal, which is equal and even superior to the elastic limit of the iron and mild steel which is usually employed. Therefore, before the crushing of the concrete, the reinforcing bars are almost always stressed up their elastic limit, unless the elastic limit of the bars be exceptionally high or the concrete exceptionally poor.

This stress cannot be appreciably surpassed because a very great decrease takes place in the value of the coefficient of elasticity of the metal as soon as the elastic limit has been exceeded, and the stresses increase, therefore, with an extreme slowness which is limited by the small deformations which the concrete can still undergo without crushing.

Hence, it may be stated that *in concrete members reinforced by longitudinal rods connected by cross pieces or ties too weak or too far apart to bind the concrete sufficiently together crosswise, the total resistance to crushing varies little from the sum of the resistances offered by the crushing strength of the concrete and the longitudinal bars when stressed up to their elastic limit. During the elastic period the metal, which has been compressed before by the shrinking tendency of the concrete, causes important stresses.*

II. *Concrete Reinforced by Transverse Rods.*—Whatever the mode of rupture of concrete in compression, the crushing of the same must be retarded by the use of reinforcing rods put in planes perpendicular to the direction of the external pressure and sufficiently near to each other. The tendency to slide along oblique planes is, indeed, resisted by reinforcing bars which cut these planes, whether parallel or perpendicular to the direction of the pressure. Rupturing along surfaces parallel to the pressure is directly opposed by transverse reinforcing.

The idea of using transverse reinforcing is not new, and, while it may be still older, it is sufficient to mention that it was experimented upon in 1892 by Koenen and Wayss. Since then Harel de la Noé has theoretically explained the advantages of transverse reinforcing and has made and inspired some very interesting applications. The transverse reinforcing may consist of a series of rods placed on diameters, all passing through the center of the section, or of a net with rectangular openings, or of circumferential rods which constitute hoops embedded in the concrete to a depth required to protect the metal from the action of atmospheric influences.

The author has not made any experiments on the first system which concentrates the metal around the center where it is the least useful. He has limited his preliminary experiments to reinforcing consisting either of circumferential hoops or of netting wires at right angles and parallel to the sides of the section. For equal weights of metal the resistance to crushing was appreciably more than twice as great for the circumferential reinforcing as for the wire netting.

Without entering into a theoretical discussion, the above result can be explained by a simple observation. If the external layers of a prism reinforced by rectangular wire nets are considered the lateral thrust outwards to which they are subjected to by the pressure at their base will in nowise be resisted by the rods parallel to these layers or faces, and nothing prevents them from separating from the central mass simultaneously with the concrete in which they are embedded. Of course, the bars at right angles to the faces considered offer a resistance to the outward thrust, but only to such extent as they adhere to the concrete. This adhesion is proportional to the area of contact, and is zero at the ends and only increases in intensity as the distance along the bars increases from the faces, but these faces are just the layers most exposed to crushing. To remedy this fault the author has first employed iron rods so connected as to support each other, and then nets of wires interwoven in a manner which promised the best results. After all these arrangements the crushing beginning at the face has gradually spread towards the center and it became apparent why, for equal weights of steel, not more than one-half of the resistance shown by the hooped concrete was obtained. It was as a result of the above experiments that all further investigations were directed to concrete reinforced by hoop-like rods.

III. *Theoretical Considerations on the Resistance of Hooped Concrete.*—The inner forces acting in solid bodies are often placed in two different classes. The name, cohesion, is generally given to the inter-molecular action, and it is known that it varies in proportion to the distances of the molecules from each other up to a certain point which is called the elastic limit. As a premise nothing is supposed to be known of the effects produced by cohesion above the elastic limit; but at the same time it is generally admitted that friction exerts an action in the interior of bodies similar to that exerted on their surface. Leaving purely academical discussions, the following method was adopted for investigation.

A certain number of prisms of concrete of different qualities and surrounded by hoops of various arrangements and sizes was prepared. Some had, also, longitudinal reinforcing rods. These prisms were submitted to increasing pressures and the shortenings produced were measured together with the loads. By a well known formula for earth thrust, the resistance was computed which would be offered by a prism of same dimensions reinforced in the same way if in place of the concrete sand without cohesion were put. The same coefficient of friction was assumed and the same percentage of swelling of cross-section to decrease of length. This was computed for each observed deformation. It is evident that the excess of the observed resistance of a concrete prism over the similar resistance of sand corresponding to the same deformation can only be attributed to the direct or indirect effects of the cohesion of the concrete. The author has named this excess the specific resistance of the concrete.

Sand, of course, cannot be reinforced by hoops but must have a continuous shell. It is easily shown that the resistance given to the sand by the shell is 2.4 times as much as could be offered by longitudinal reinforcing rods of the same weight as the shell, with the same stress. The ratio of the efficiency of the two types of reinforcing is therefore as 2.4 to 1. Sand is taken here as an example of cohesionless body.

IV. *Experimental Researches.*—The above considerations referred to bodies without cohesion; and it is important to determine whether in concrete the effects of cohesion act in addition to friction and in what way. The beginning was made by experiments to verify the agreement of the resistance of a sand cylinder in a shell with the formula for earth thrust above mentioned. This has been fully verified and the value 2.4 was checked by experiment. A first series of experiments was then made at Quimper, in 1901, on small prisms of mortar 1.6 inches in diameter hooped by a fine iron wire. The deformations have not been measured and the results obtained can, therefore, only be used to verify the resistance to crushing and to compare the same to the assumptions made above. The accompanying table shows the results obtained from some of the prisms.

The figures given in the table are significant. The iron wire employed for the hooping was drawn cold and did not have a definite elastic limit. From its curve of deformation 78,200 pounds per square inch appeared to be the proper value after passing which the stress in the metal increased too slowly for its elongation to be able to maintain the real efficiency of the reinforcing. This value of 78,200 pounds per square inch has been multiplied in the above table by the ratio of iron to concrete, giving the values in the next to last line, representing the compressive resistance which would have been offered by the metal if it were used as longitudinal reinforcing bars instead of hooping wires. The ratios obtained in the last line of the table thus give the coefficient of efficiency from the point of view of the compressive resistance of metal employed in longitudinal reinforcing or in hooping. For sand, as seen above, this ratio is 2.4 and the figures of the last line show that for mortar this ratio has not deviated far in the above experiments.

The compressive values obtained should be noted. Of the above described prisms a single one was of mortar which had had time enough to set. With a volume of metal equal to 0.034 of the total volume and without any longitudinal reinforcing it showed a resistance of 10,500 pounds per square inch of total section. It will be useful to compare the resistance of this prism with the resistance of an iron prism of the same weight. The hooped concrete had a density of 2.4, and that of iron is 7.8. To compute the pressure which an iron bar of the same weight will get per square inch of section, 10,500 must be multiplied by 3.2, the ratio of the densities of the two materials, and 33,600 pounds per square inch is thus obtained for the iron. Since not more than 36,000 to 39,000 pounds per square inch can be expected of the total area of a riveted iron section weakened by numerous holes, it may be said that a prism of an ordinary mixture reinforced by an average percentage of hoops, has shown a compressive resistance in the neighborhood of that of ordinary iron.

Weight of Cement per Cubic Yard of Sand:	675 Pounds				730 Pounds.
Age of mortar tested, days	8	14	22	23	100
Ratio of volume of iron to volume of concrete	0.02	0.03	0.04	0.02	0.034
Resistance to crushing in pounds per square inch of total section	4,870	6,540	7,360	4,930	10,500
Resistance to crushing of concrete not reinforced	569	711	853	853	2,420
Increase of resistance due to hooping	4,301	5,829	6,507	4,077	8,080
Product of ratio of iron to concrete by 78,200 pounds	1,564	2,346	3,128	1,564	2,658
Ratio of the values of the last two lines	2.7	2.5	2.1	2.6	3.0

It will be seen in what follows that the results of hooping are less advantageous for the coefficient of elasticity and, therefore, for the resistance to flexure as a column than for that of the crushing resistance. To study this question experiments had to be made on long members and their deformations measured. With the aid of M. Hennebique, 38 prisms of octagonal section of 5.9 inches diameter were made. Different reinforcing was embedded, and the concrete consisted of the usual mixture of 1,000 pounds cement to 45 cubic feet of gravel and 22.5 cubic feet of sand, in some prisms, and double the amount of cement in others. Some prisms had a length of 1.64 feet and were especially intended to test the crushing resistance; the others had a length of 4.25 feet and were used to study the elasticity and the ductility of hooped concrete, which is one of its characteristic properties and one of the most important for safety. Prisms of 11.8 inches diameter have also been prepared and they will be broken in a 1,100,000 pounds testing machine.

Each specimen teaches its lesson, but it is plainly impossible to describe all the results obtained, comprising about 1,200 observations of deformations. They have, therefore, been grouped so as to throw most light on the important points.

The first group consists of 6 prisms. Prism A was not reinforced. It crushed under a load of 1,050 pounds per square inch. Prism B was reinforced with helicoidal spirals of 5.5 inches average diameter made of cold drawn ¼-inch iron wire spaced 1.18 inches centers to centers. It crushed under a pressure of 5,120 pounds per square inch of total section. Prism C was reinforced by helicoidal spirals of 5.5 inches average diameter made of cold drawn iron wire of 0.17 inch diameter and spaced 0.59 inch centers to centers. Without crushing it stood a pressure of 5,400 pounds per square inch, which was the highest pressure supplied by the testing machine employed. Prisms D and E were armored respectively the same as B and C, and in addition they were reinforced by 8 longitudinal wires ¼ inch in diameter leaning against the inside of the spirals. They failed as columns, before crushing, under pressures of 4,550 to 4,700 pounds per square inch. Prism F had 8 longitudinal reinforcing wires 0.35 inch diameter tied together by belts of iron wire 0.17 inch diameter spaced 3.15 inches apart, that is, closer than they are usually in concrete steel constructions. It failed under a pressure of 2,420 pounds per square inch. The following phenomena were noticed without the aid of measuring devices.

V. *General Properties of Reinforced Concrete and Hooped Concrete.*—The non-reinforced prism A broke suddenly, without any signs of approaching danger. The failure of F was almost as sudden. Its breaking load did not exceed by more than 7 per cent. the load producing the first cracks. The reinforcing rods bent outwards between their cross connecting ties and the concrete crushed. Concrete in compression when not reinforced or when reinforced by longitudinal rods must be classified among the materials which break suddenly without much deformation. Quite different is the behavior of hooped concrete as will be seen.

The hooped prisms behaved at the beginning the same as the others and showed only very small deformations under small loads; but this so-called elastic period did not end with the failure of the specimen. The shortening was observed to increase rapidly and cracks appeared in the concrete covering the hoops, first fine, then more and more pronounced. Rough measurements showed that failure took place after deformations as great as 3 per cent. of the length. By comparing the percentages of the iron to the concrete with the corresponding crushing resistances the considerable superiority of hooped concrete, from this point of view, becomes evident. The table giving the results of the Quimper experiments shows this very clearly. It may be added that the results of this group of experiments have shown at once *that while concrete not reinforced or reinforced by longitudinal rods, even when tied together by ties appreciably nearer to each other than is usually the case, breaks in compression under small deformations and without any notice, hooped concrete sustains, without crushing, considerably heavier loads and only fails a long time after cracks in the faces and exaggerated deformations have called attention to the approaching danger.*

(To be continued).

The Department of Bridges of New York City has been assigned an official photographer, who will make all progress photographs of the work of the department.

The Character of Waters used in irrigation, especially in the growing of rice, is being studied by the Bureau of Chemistry, Department of Agriculture, to determine the quantity of injurious salts which these waters may contain and the quantities of this water which may be safely used upon the fields.

Large Transit Undertakings.

The two cities which have taken a leading part in the solution of metropolitan rapid transit problems have recently taken decisive steps towards additional extensive construction for improved transit facilities. By a very large majority at the recent elections, the citizens of Boston, on popular referendum, accepted the act providing for new subways which will greatly enlarge the present underground transportation system. The new subways are intended to facilitate travel into and through some of the most congested parts of the city. The design and construction of these subways will be under the charge of the Boston Transit Commission. Details of the project have not yet been fully determined.

About a year ago the Pennsylvania Railroad made public a project for tunneling beneath the North and East rivers and the boroughs of Manhattan and Queens, New York City, for the purpose of connecting its terminals in New Jersey with the Long Island railroad systems and obtaining direct entrance to the heart of New York. The work was outlined in The Engineering Record of December 14, 1901. The Rapid Transit Commission represented the city in the negotiations, but final action upon the franchise came within the province of the Board of Aldermen. After the matter had been under consideration for several months, the Board voted, 41 to 36, on December 16 to grant the franchise. Clauses providing for an 8-hour day, the prevailing rate of wages and the submission of labor disputes to arbitration, upon which many of the aldermen insisted, were steadily rejected by the railroad officials, and the franchise as granted does not contain them. The franchise is perpetual, but terms of rental are subject to readjustment at intervals of 25 years; and the franchise cannot be transferred excepting to a New York corporation, which must comply with all its provisions. The power to be used for propulsion of trains through the tunnels shall be electricity or other form of power not requiring combustion within the tunnel. Construction, it is required, shall begin within 3 months, and shall be completed, ready for operation, within 5 years. The cost of construction and real estate is roughly estimated at $50,000,000. The city may utilize the tunnels for fire and police telephone and telegraph wires, and shall have sanitary and police control of them.

An Examination for Architectural Draftsmen will be held by the Municipal Civil Service Commission of New York, January 19, 1903. Receipt of applications will close January 15. This examination will be divided into two parts: First grade, salary $750 or less per annum; third and fourth grades, salary more than $750 but not more than $1,200 per annum. For particulars address Mr. S. William Briscoe, secretary, 61 Elm Street, New York.

Fire Insurance Rates in Brooklyn have recently been increased from 20 to 30 per cent. on property in business and manufacturing sections of the borough because of inadequate water supply for fighting fires. The great number of small and old pipes in the distribution system are said to be responsible for curtailing the quantity of water and reducing the pressure at hydrants. To relieve this unfortunate condition it is proposed to lay additional large trunk mains and replace some of the oldest and smallest pipes with new mains of larger size. Brooklyn's experience may well be taken as a lesson by some other municipalities. Computation will often show that the saving in fire insurance premiums alone would pay for large extensions of water-works.

A Fire Test of Doors.

A fire test of two doors composed of deal and uralite, is described in a recent report of the British Fire Prevention Committee. Uralite is a patented product marketed by the British Uralite Company, Ltd., of London. It consists of asbestos fibers, crossed and interlaced, with which a small quantity of chalk is mixed. This mass, in the form of a pulp, is spread out into sheets, materials being added to cause the conformation of gelatinous silica. The board is then dried, and is repeatedly treated with chemicals to cause the deposition of silica within its pores. After each deposition, it is dried and heated, and resulting carbonate of soda is washed out. The doors were constructed of two thicknesses of white deal, each ⅞ inches thick, one set being vertical and the other horizontal, with one layer of soft uralite between and one layer of soft and one of hard uralite on the outside faces. One of the doors was armored by a covering of tinned sheet steel, 0.022 inch thick. The doors were approximately, 2 feet 9 inches by 6 feet 6 inches and 2¼ inches thick, and were placed in one wall of a fire brick testing chamber, 10x10 feet in area and 9 feet high. Mixed air and gas was introduced below the floor of the chamber and burned within it. The test lasted 90 minutes, during which time the maximum temperature reached was 1,780 degrees, and the average about 1,320 degrees. The doors were supported by two heavy hinges and secured by two bolts at the top and bottom. At the conclusion of the test the doors were cooled with water. The unarmored door was buckled ¾ inch outward between the bolts, and slightly less than that between the hinges. The outer thickness of uralite was not damaged, but the upper inside layers were broken away, being carried away by the application of water. The inner thickness of wood was carbonized throughout; the center layer of uralite was cracked and damaged; and the outer thickness of wood was partly carbonized. The steel-covered door was buckled ⅜ inch outward between the bolts, and slightly less between the hinges. The plates on the outside were not damaged, but those on the inside, while still in position, were badly warped toward the fire and the joints slightly opened. Upon removing one of the steel plates, it was found that the inner thickness of boarding was carbonized; the center thickness of uralite was not harmed, and the outer thickness of boarding was discolored but not much damaged.

Since the foregoing account was written, some further information has been obtained concerning uralite from a report of Consul-General Oliver J. D. Hughes, at Coburg, Germany. It is the invention of a Russian artillery officer and chemist, named Imschenetzky. The process of manufacture is akin to that employed in paper making, and commences in what is known as a "preparation building," where the crude asbestos is first of all "teased" out and freed from sand and other foreign substances. It is carefully graded and separated and passes onto edge runners, where a small portion of whiting is added to prevent grinding rather than the loosening of the fibers which is desired. From the edge runners it is conveyed by elevators to a floor above, where it is fed into a Krupp disintegrator which further loosens the fibers. It is again separated by air blasts and by sieving, and is then ready for the next stage.

In another building, the asbestos is mixed with an equal weight of whiting, if white uralite is being made; or if gray or red uralite is needed, this is replaced by carbon black or red oxide. The whiting is first reduced to a cream by beating it up with revolving paddles in a mixer. This is passed through a sieve for the removal of accidental impurities, and thence into a "hollander." The asbestos is next added, the usual charge being about 600 pounds, and then the coloring matter. The whole is worked up into an emulsion by revolving screws and beaters, for a quarter of an hour or so, and there is a further separation to remove any sand which may have hitherto escaped detection.

The uralite pulp then passes to a machine designed on much the same lines as that employed in making paper boards. The pulp is delivered over riffle boards onto an endless revolving blanket, and passing through a series of rolls is partially dried and compacted. It then passes onto a revolving drum at the end of the machine, on which some fourteen or fifteen thicknesses are deposited before the required thickness is attained. During the process of winding onto the drum, a solution of sodium silicate, with an amount of sodium carbonate insufficient to permit of the immediate deposition of the silica, is passed over the successive fibers of asbestos and serves as an adhesive.

The large sheets, as they are taken from the drum in their pliable state, are quickly cut to smaller ones, measuring 6 feet 2 inches by 3 feet 1 inch. These sheets are piled up, alternating with sheets of wire gauze or sheet iron, to a height of about 40 inches. The pile is then placed under an hydraulic press and the pressure slowly increased, until at the end of half an hour it is about 200 pounds per square inch. This is maintained for one and one-half hours, and the pile is then left to harden for 24 hours, after which the sheets are removed to go to the storing rooms. Here, they are placed vertically in racks on trucks, and pass through a series of gas-fired stoves with graduated temperatures. They are then steeped in a solution of sodium silicate, washed, left to dry, and again passed through a stove, after which they are steeped in a solution of sodium carbonate, and washed and dried as before. These subsequent operations are repeated as often as required for the final hardening of the sheets, and the entire process occupies several days. The sheets are stacked for some days and again passed through the stove, being then ready for use, though they are the better for a little seasoning. The sheets of uralite thus produced are found to be uniform in thickness, 3/32 inch being the standard.

It is stated that under test a cube 1 inch square, built up with sections, cut from standard sheets, was subjected to a pressure of 19.8 tons before it gave way. A strip 9¼ inches long, 1½ inches broad, and 7/64 inch thick, placed between supports and gradually subjected to an increasing weight placed at its center, did not break till a weight of 15 pounds had been applied.

The Sederholm Boiler.

The Sederholm boiler is a modification of a horizontal return tubular boiler, the principal change being the addition of several transverse water heating drums below the main part of the boiler with the object of increasing the heating surface per square foot of ground occupied and thus overcoming an objection that has been made to the horizontal tubular boiler as usually designed. The drums in the Sederholm boiler extend entirely across the furnace and combustion chamber and they are sufficient in number and diameter to compel the gases to pass to the rear of the setting before coming in contact with the shell above. The gases then pass forward above the drums and below the shell and backward again through the tubes in the shell. Each drum is connected at each end and in the middle to the shell above by means of water passages consisting of large pipes with flanges riveted to its ends and to the drum and shell.

In 1901 several tests of these boilers were conducted by Mr. Albert C. Wood, M. E., of Philadelphia, Pa., and the results have been printed in a recent catalogue of the Allis-Chalmers Company, of Chicago, the builders of the boiler. Two boilers were tested, each having a main shell 8 1/3 feet in diameter, 16 feet long and containing 190 3½-inch tubes. Each boiler was equipped with four furnace drums 30 inches in diameter and 12 feet 2 inches long. The tube heating surface was 2,786.6 square feet, the drum heating surface 139.2 square feet and the rear tube sheet 25.8 square feet. As the grate surface was 51 square feet the ratio of heating to grate surface was as 57.8 to 1. Lahman-Kirkwood shaking grates were used.

Three trials were made, the first with "New Kentucky" Illinois screenings, the second and third with "New River" semi-bituminous, run-of-the-mine coal. The heat value of the former coal was 12,870 B. T. U. per pound of dry coal, as determined by calorimeter, and of the New River coal, by Dulong's formula from the ultimate analysis, 14,932 B. T. U. per pound. The principal results are given in the accompanying table:

Results of Trials of Sederholm Boilers.

Date of trial	Apr. 18	Apr. 22	Apr. 19
Duration of trial, hours	11.	13.	13.6
Average steam pressure in boiler, pounds	117.6	117.6	110.6
Average draft in flue, inches	0.25	0.46	0.44
Average temperatnre waste gases, degrees F.	520.	573.	516.
Average temperature feed water, degrees F.	199.6	200.6	199.0
Kind of coal	New Kentucky	New River	New River
Moisture in coal, per cent.	5.54	1.56	2.31
Per cent. refuse in coal	10.5	7.8	6.9
Water evaporated per pound dry coal actual conditions, pounds	8.51	10.31	9.98
Equivalent water evaporated per pound dry coal from and at 212 degrees F., pounds	8.99	10.88	10.53
Equivalent water evaporated per pound combustible from and at 212 degrees F., pounds	10.05	11.80	11.31
Water evaporated from and at 212 degrees F. per square foot heating surface per hour, pounds	3.87	4.38	3.43
Dry coal burned per square foot grate per hour, pounds	24.9	23.3	18.8

Experimental Septic Tanks, with nitrifying filters, were operated in Altoona, Pa., from September 16 to November 10 to study the applicability of this method of treatment to the dilute sewage of the east end of the city. During the experiments the rate of sewage flow varied from 3,080,000 to 4,023,000 gallons per day, excepting during five brief periods of flood caused by rain. According to the report submitted to the city council by City Engineer Harvey Linton and embodying analyses by Dr. C. B. Dudley, chemist to the Pennsylvania Railroad, the results were not at all satisfactory. This unfavorable outcome of the experiments is supposed to be due to the presence in the sewage of the drainage from the gas works, there being 527 parts of free ammonia per million in this drainage, a sufficient proportion to be detected by the characteristic odor. Besides this large proportion of ammonia, the drainage from the gas works contained some cyanide, sulphides, sulpho-cyanides and tarry matter. It is possible, however, that the diluteness of the sewage is in part responsible for the poor action of the septic tank. It is proposed to prosecute the experiments, eliminating the gas house drainage from the sewage. Mr. Allen Hazen, of New York, has been retained to confer with the city engineer in the further study of the subject. The Engineering Record is indebted to Mr. Harvey Linton, city engineer, for the above.

Grouting Subaqueous Walls.

An interesting example of what can be accomplished with cement under water is found in a lock and weirs recently constructed in Egypt. The lock foundations were got in entirely by grouting, and, as it is believed that this system has never been applied to such an operation before, it may be useful to abstract the description published in "Indian Engineering."

The foundation bed was prepared by dredging. The walls were made in sections by depositing the materials inside bottomless boxes formed in place from a floating platform supported by two barges moored in position. The boxes were 29 feet long, 10 feet wide and 26 feet high. A horizontal timber frame was supported from the barges at the water surface and a second frame, weighted with old rails, hung by chains from the upper frame so as to be 13 feet below it. The sides of the box were then formed of sheet piles one foot wide, fastened together in sets of five, weighted at the bottom so as to float vertically, and shod with sheet iron in order to make a good joint with the river bed and prevent the escape of grout. The construction is shown in the accompanying illustration.

When the sides of the box had been formed, the whole interior surface was lined with sacking, overlapping at the angles and at the junction with the river bed. The sacking was kept in place and protected from being torn by the rubble, during filling, by nailing thin planks about 3 feet apart against it from water surface to bed. Divers were constantly at work during these operations. Four perforated pipes were then fixed along the axis of the box at equal distances, and the box filled with rubble and concrete metal (20 per cent.) and pebbles (15 per cent.) thrown in up to slightly above water level. Pipes without perforations were then inserted into two alternate perforated pipes, reaching nearly to the bottom of the box; on the tops of these pipes were screwed funnels, and over the funnels were fixed coarse wire sieves to catch the pieces of paper of the cement barrels and other foreign substances that might get mixed with the cement grout. In the other two pipes, floats which sank in water and floated in cement grout, were suspended, so that the rise of the grout might be watched. The object of grouting through an inner pipe without perforations was to deliver an unbroken column of grout at first at the bottom of the box, and afterwards have the grout ascend towards the surface of the sea. If grout were poured directly into the perforated pipe, each bucket of grout would have to fall through water. The inner pipes were changed over from time to time to the alternate perforated pipes, and gradually shortened as the grout rose. To lessen the danger of leaks at the bottom of the box from the pressure of too great a head of liquid grout, (which being twice as heavy as water exercises a pressure in water equal to the pressure exerted by a head of water in air), it was generally arranged that a depth of three feet should be grouted over night, and left till the next morning to set, so as to form a solid bottom to the box on which the rest of the grout would be supported.

The grouting was continued next day until the grout rose slightly above the water surface: the scum was cleared away, and stones put by hand into all the spaces where there was an excess of grout. The block was then left for the night, and next morning was found to have set hard enough for the box, in which it was formed, to be loosened and moved forward.

The second and subsequent boxes were made as three-sided boxes, the last grouted block forming the fourth side and being clasped by the side beams of the horizontal frames.

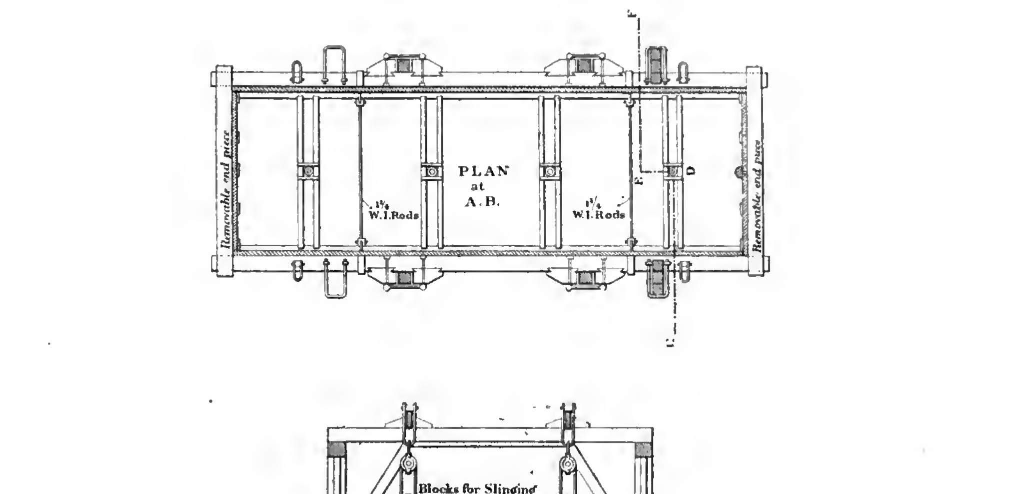
A box and its contained block took from three to four days to make, so that, when four rafts were at work, the average rate of progress was about 33 feet of core-wall or lock-wall a day. Each block contained about 210 cubic yards of masonry, and was about 29 feet long by 10 broad and 20 high.

The cement grout was mixed by hand in iron troughs by ordinary laborers. The consistency of the grout varied from thin to thick, the proportion of water depending on the judgment of the mixers. Experiments and experience on the work itself seemed to show that, whether thin or thick, the cement grout set satisfactorily and gave the desired result. Whatever the explanation, it appeared to be unnecessary to be particular about the proportion of water in the grout when used as in the work described, but it is necessary to be careful to get a cement that will behave satisfactorily under such severe conditions, and this appears from experiments made with many kinds of cement not to be difficult.

In constructing the lock, two parallel walls, bounding the lock area on either side, were formed by the system adopted for the core-wall. The rectangle of which these walls formed the sides (330 feet long by 56 feet broad between the walls) was then closed at the two ends by sheet piles supported by horizontal beams, which were kept in place by piles driven a short distance into the bed of the river and tied at their tops to the side walls already formed. A staging was then constructed across the enclosed space from wall to wall, and the perforated pipes fixed in place about 11 feet apart all over the area. Six feet depth of rubble, concrete metal and pebbles were then thrown in to form the floor foundation. At about three feet from each end a second interior cross wall of sheet piling was arranged with the lower end below the level to which the six-foot layer of rubble would come. All the sheet piling was lined on the inside with sacking to prevent the escape of grout between the joints, in the same way as in the boxes.

When the six-foot depth of floor material had been deposited, grouting commenced at one end of the lock and continued day and night for 89 hours till the other end was reached. The end walls were then filled and grouted. The enclosed space was pumped out in half a day, and the grouting was found to have formed a perfect floor without the sign of a spring in it. The rest of the lock floor and walls was built in the dry in the ordinary manner.

As the grouting was executed under water and was not continued, as in the boxes, until the grout rose above the water surface, arrangements had to be made for ascertaining to what level the grout had risen. A simple arrangement revealed this. The grout was poured into alternate pipes, and in the other pipes floats were suspended that would sink in water and float in cement grout.

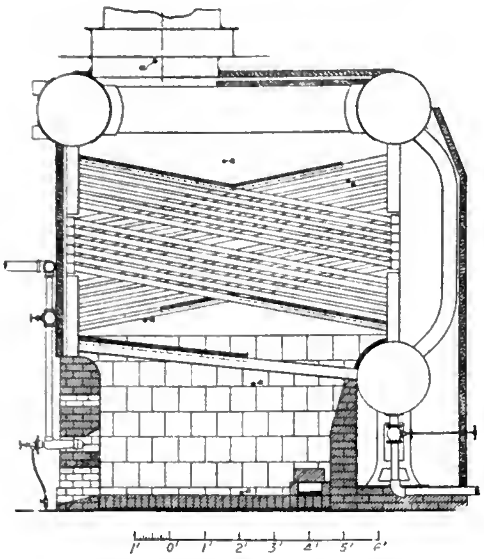


SECTION C.D.E.F.

Barges and Box for Constructing Subaqueous Walls.

Naval Tests of a Water Tube Boiler.

One of the most important series of boiler trials ever made is that reported by a board of naval officers in the recent annual report of Rear Admiral George W. Melville, Chief of the Bureau of Steam Engineering of the Navy Department. Two series of trials, one with coal and the other with oil fuel, were made on a boiler of the Hohenstein water-tube marine type built by the Oil City Boiler Works, of Oil City, Pa. The tests are of particular value because of the different conditions under which they were conducted and also because they give data bearing on the relative value of Texas oil and of two well known steam coals. The board of officers consisted of Lieut. Commander John R. Edwards, U. S. N.; Lieut. Commander Wythe M. Parker, U. S. N.; and Lieut. Commander Frank H. Bailey, U. S. N. The tests were conducted at Washington, D. C., in an air-tight steel house of dimensions corresponding to those of the fire room of the cruiser "Denver," in which boilers of the same type are to be installed. An illustration of the boiler is shown. The upper transverse drums are each 24 inches in diameter and are connected by four drums 16 inches in diameter. There are 384 2-inch tubes, 9 feet long, and 16 4-inch tubes, 7 feet long, the latter being placed over the furnace. There are also 15 5-inch down-take tubes in the rear. These are not exposed to the gases. The floor space occupied by the boiler is 9 feet wide and near 11 feet deep. The heating surface was 2,174 square feet for coal tests 15 to 20 inclusive and 2,130 square feet for coal tests 21 to 31 inclusive. The grate surface is 50.14 square feet, making the ratio of heating to grate surface 43.4 to 1 and 42.5 to 1 for the two series. The air spaces in the grate bars for the coal trials were ⅝-inch for tests 15 to 25 inclusive and ½ inch for tests 16 to 31 inclusive. The stack was 70 feet high above the grate and of 8.7 square feet sectional area.



THE HOHENSTEIN WATER-TUBE BOILER.

COAL AND OIL TESTS OF A HOHENSTEIN WATER TUBE BOILER.

					Average pressures.					Average temperature (Deg. F.).					Fuel.

COAL AND OIL TESTS OF A HOHENSTEIN WATER TUBE BOILER (Concluded).

	Economic results.						Chimney gas analysis.							Heat balance or distribution of the heating value of the fuel. In percentages of the total heating value.							Efficiency.	
Number of trial.	Feed water per lb. of oil or coal as fired (lbs.).	Equivalent evaporation from and at 212° F. per lb. of oil or dry coal (lbs.).	Lbs. of steam used in spraying oil per lb. of oil.	Steam used in spraying oil (per cent. of total steam generated).	Cubic feet of free air used in spraying oil per lb. of oil sprayed.	Equivalent evaporation from and at 212° F. per lb. of combustible (lbs.).	Carbonic acid, CO_2 (per cent.).	Oxygen, O (per cent.).	Carbonic oxide, CO (per cent.).	Nitrogen, N (per cent. by difference).	Lbs. of dry chimney gas per lb. of carbon.	Lbs. of dry chimney gas per lb. of oil.	Heat value of 1 lb. of oil or coal calculated from chemical analysis.	Heat absorbed by boiler.	Loss due to superheating steam used in spraying oil.	Loss due to moisture in coal (per cent.).	Loss due to moisture formed by the burning of hydrogen.	Loss due to heat carried away in dry chimney gases.	Loss due to incomplete combustion of carbon.	Other losses—radiation, etc.	Of boiler (per cent.).	Of boiler and furnace.

The steel house in which the boiler was located was provided with an air lock for entrance and exit during forced draft trials and windows that could be opened during natural draft trials. A 72-inch fan discharging into the room was provided for forced draft. Coal and water were both accurately weighed. The flue temperature in the natural draft trials was taken by a mercury nitrogen pyrometer, but on the forced-draft runs so many glass bulbs were broken that a Brown quick-reading pyrometer was used, the readings of which were checked by the melting prints of zinc, aluminum and copper.

Samples of flue gas were drawn by means of an aspirator improvised from two half-gallon bottles. The sampling tube was ½ inch in diameter and extended to the center of the stack, the inner end being nearly closed and the sides perforated with small holes. Analyses were made by the Orsat apparatus.

The accompanying table gives the results of analyses of samples of each lot of coal made by the chemist in the New York navy yard:

ANALYSES OF COAL.

	A		B	C
Boilers in test, by No....	15—17	18—20	21—23	24—31

A—Pocahontas coal, run of mine.
B—New River coal, run of mine.
C—Pocahontas coal, hand-picked aud screened.

The oil tests were made on the same boiler, the grates being removed. Oil was pumped from a storage tank into a weighing tank from which the oil flowed by gravity to the oil-feed tank. From this the oil was pumped to the burners, constancy of pressure being secured by an air chamber and a relief valve. An overflow pipe led from the relief valve to the feed tank. The weighing and feed tanks were fitted with gauge glasses graduated to 5 pounds by the aid of which the exact weight of oil was secured at the end of each hour. The feed water was measured at hourly intervals in the same manner. The air for atomizing the oil was supplied by a Root blower. In determining the amount of steam used by the oil burners, in some of the tests, in which steam was used for atomizing purposes, a separate boiler was used to furnish the steam.

The oil used was from the Beaumont field and was subjected to an inexpensive treatment to remove the sulphur and some of the more volatile hydrocarbons. Analyses showed the oil to be composed of 83.26 per cent. carbon, 12.41 per cent. hydrogen, 0.50 per cent. sulphur, 3.83 per cent. oxygen. The specific gravity at 60 degrees Fahrenheit was 0.926; the flash point, 216 degrees; the fire point, 240 degrees; vaporization point, 142 degrees. The loss for six hours' exposure at 212 degrees Fahr., was 21.65 per cent. The calorific value of the oil by the Dulong formula is 19,481 British thermal units per pound.

The board expresses the belief that expert engineers will be able to make important deductions from the trustworthy data that it secured. The data and results of the coal and oil tests are given in the accompanying tables. The conclusions of the board of engineers are as follows:

That oil can be burned in a very uniform manner.

That the evaporative efficiency of nearly every kind of oil per pound of combustible is probably the same. While the crude oil may be rich in hydrocarbons, it also contains sulphur, so that, after refining, the distilled oil has probably the same calorific value as the crude product.

That a marine steam generator can be forced to even as high a degree with oil as with coal.

That up to the present time no ill effects have been shown upon the boiler.

That the firemen are disposed to favor oil, and therefore no impediment will be met in this respect.

That the air requisite for combustion should be heated if possible before entering the furnace. Such action undoubtedly assists the gasification of the oil product.

That the oil should be heated so that it could be atomized more readily.

That when using steam higher pressures are undoubtedly more advantageous than lower pressures for atomizing the oil.

That under heavy forced-draft conditions, and particularly when steam is used, the board has not yet found it possible to prevent smoke from issuing from the stack, although all connected with the tests made special efforts to secure complete combustion. Particularly for naval purposes it is desirable that the smoke nuisance be eradicated in order that the presence of a war ship might not be detected from this cause. As there has been a tendency of late years to force the boilers of industrial plants, the inability to prevent the smoke nuisance under forced-draft conditions may have an important influence upon the increased use of liquid fuel.

That the consumption of liquid fuel cannot probably be forced to as great an extent with steam as the atomizing agent as when compressed air is used for this purpose. This is probably due to the fact that the air used for atomizing purposes, after entering the furnace, supplies oxygen for the combustible, while in the case of steam the rarefied vapor simply displaces air that is needed to complete combustion.

That the efficiency of oil fuel plants will be greatly dependent upon the general character of the installation of auxiliaries and fittings, and therefore the work should only be intrusted to those who have given careful study to the matter, and who have had extended experience in burning the crude product. The form of the burner will play a very small part in increasing the use of crude petroleum. The method and character of the installation will count for much, but where burners are simple in design and are constructed in accordance with scientific principles there will be very little difference in their efficiency. Consumers should principally look out that they do not purchase appliances that have been untried and have been designed by persons who have had but limited experience in operating oil devices.

The Consumption and Waste of water in Washington, D. C., measured on June 24 of this year was found to be 205 gallons per capita, the largest June measurement ever taken.

Work on the erection of the $1,120,000 suspended span of the New East River Bridge, New York, which was delayed by the tower fire on November 10, has just been commenced. The steel work has been connected to three sets of suspenders next the Brooklyn tower, and the steel traveler there is being erected. Work at the New York end is still delayed by the effects of the fire, but will soon be started, and a duplicate traveler will be erected there and work will progress simultaneously from both ends to the center of the span. The Pennsylvania Steel Company is the contractor.

Tar and Oils on Roads in France.

Tar and oils on roads have been experimented with at Champigny, near Paris, under the supervision of M. Silvain Dreyfus, Ingénieur des Ponts et Chaussées for the Department of the Seine. According to "The Surveyor" the task was undertaken at the instigation of the medical authorities, who viewed with anxiety the increasing production of dust clouds resulting from motor-car traffic. In order to arrive at some definite results, three different roads were selected—one being newly made, a second in good state and the third in bad repair. Portions of these were treated with (1) coal-tar (supplied by the Compagnie Parisienne du Gaz), (2) heavy oils (petroleum residuum), (3) shale oil, (4) Texas petroleum, and (5) "Injectoline" (a patent preservative fluid for injection into wood).

The coal-tar was heated before use. For treating small surfaces, about 20 square yards, the following appliances were used: The tar was placed in tilting cauldrons of about 15 gallons capacity, supplied with a thermometer, and placed over a small furnace, which could be quickly withdrawn, the aim being to raise the temperature to about 140 degrees Fahr., not above, as when nearing 176 degrees Fahr. the tar froths and becomes unmanageable. When ready the tar was tilted into watering cans of about 5 gallons capacity, provided with flat roses, semi-circular in form. To the roses were attached two small runners, which facilitated the work and kept the can at a regular and constant height. For large surfaces, 150 to 250 square yards, different appliances were employed. An iron barrel, of about 60 gallons capacity, was mounted on a two-wheeled trolley, and was provided with a distributor of about 1¾ yards, and pierced with holes like that of a watering cart. The furnace, also on wheels, was independent, and could be run under the barrel and instantly withdrawn, when the thermometer marked 140 degrees Fahr. Both these appliances enabled the tar to be thinly and evenly distributed, so that only slight raking is necessary. They were also used for distributing the heavy oils, which were slightly heated, to overcome their viscous condition.

It was found that tarring roads in bad condition was most inadvisable, because the tar tends to accumulate in ruts and depressions, so that it is difficult to obtain an equal distribution, and, moreover, the mending of such roads is most troublesome. Dampness facilitated the penetration of coal-tar; but it was found that this penetration was limited, and that the lower surface could not dry, and as a result marked strata were formed, and the upper crust was easily broken. For coal-tar sprinkling a dry condition of the road is imperative. Dust must also be removed before applying tar, because otherwise much hand labor is necessary in order to obtain equal distribution and a smooth surface. Dust is not so inconvenient if the lighter oils are used. Although it is not absolutely necessary to sand roads after treatment, it was found advisable to do so; because if no sand was used a tarred road had to be left for several days, and an oiled road for several hours, before being opened for traffic. In these experiments from about 1 quart to 5 pints of liquid were distributed per square yard. The experiments have, so far, proved satisfactory. M. Dreyfus remarks that the past summer was too wet to enable a reliable opinion to be formed as to the exact dust-laying capacities of the different materials. On the other hand, the rain does not appear to have produced an objectionable oily mud. Possibly this may be due to the care observed in the first application and the use of a moderate quantity. The three roads are to be kept under close observation during the winter, and if the result justifies it an extension of the work will be carried out next summer. So far, M. Dreyfus seems to give preference to the tarred roads.

The Preservation of Forests in Russia and their economic development has long occupied the attention of her statesmen, according to a recent report of the Russian Ministry of Agriculture and Domains. In 1888, a law was enacted which aimed at the preservation and maintenance of forests. All forests exercising influence on the natural conditions of the country are placed under the protection of the State. They are freed from land imposts, and the government manages them at its own expense. The department of forestry is under the Ministry of Agriculture and Domains, with a general director at the head, assisted by two vice-directors. The personnel of the department is recruited from the schools, of which there are two superior and thirty secondary, with a two years' course of instruction. Certain agricultural societies have special forest sections. Three trial establishments have been created in southeastern Russia, to determine the influence which the planting of trees on the steppes would have on the agricultural and economic conditions of the region. The tendency is not to plant in solid masses, but in straight lines, either from north to south or east to west, as the local conditions demand.

The Labor Law of Nicaragua of June 30, 1901, recently put into effect contains some rather startling provisions in the way of defining the relations between labor and capital.

First. A laborer is defined as any person, male or female, over 16 years of age not having a capital of 500 pesos (about $100).

Second. All laborers must have an employer. Anyone found unemployed will be imprisoned for twenty days and made to labor on public works while awaiting an employer. Every employer of labor must purchase a small booklet (cost, about 20 cents), in which are registered the name, age, description, general characteristics of the person, and conditions of the contract. The employer gives his employe a receipt for the book, which the latter can produce as proof of his good standing whenever arrested by the police on suspicion of being idle. When a laborer has finished his contract with one employer and desires to go to another, he must take his "book of labor" and present it to his next employer and take a receipt, the change being registered by the judge of agriculture.

Third. If a laborer desires money in advance, his employer can give it to him only as a loan without interest, to be paid by retaining one-half of the salary or wages until the debt is canceled. A laborer leaving his employer without satisfactory settlement of his debt will be imprisoned, fined, and obliged to return and work it out.

Fourth. Any person employing laborers without this "book of labor" will be fined 200 pesos (about $40).

The purposes of the law are to do away with the pernicious habit formerly in vogue of advancing wages to laborers on a contract, which made the laborer a slave until he settled his account, and to prevent idleness and viciousness, by obliging everyone without capital to be employed. Consul Donaldson in "Consular Reports" for December states that the law caused general consternation at first among all classes, but as it is being enforced everyone is becoming reconciled, and the general effect seems to be beneficial.

Heat Resistance of Building Materials.

At the recent meeting of the American Society of Mechanical Engineers a paper was presented by Mr. William Kent proposing the use of the reciprocals of the values of heat conductivity of substances in order to facilitate the comparison of different combinations of the substances. As stated in the report of the convention, he makes the coefficient of heat resistance or heat insulating power of a substance equal to unity divided by the number of British thermal units transmitted in one hour by a slab 1 square foot in area and 1 inch thick per degree Fahrenheit of difference of temperature between the two faces of the slab, both surfaces being exposed to still air. In this way the total resistance of a combination can be indicated by the addition of the several resistance coefficients. The author points out, however, that while the coefficient is thus a constant quantity for a given substance, it can only be so considered when the differences in temperature of the air on the two sides of the slab are small—say, less than 100 degrees Fahrenheit. When the temperature range is great, experiments on heat transmission indicate that the quantity of heat transmitted varies not directly as the difference in temperature but as the square of that difference.

The question of the effect of surface resistance when the surface is in contact with air or with another body, the author treats as follows: "Authorities on the subject of heat transmission generally agree that the resistance to the passage of heat through a plate consists of three separate resistances; viz., the resistances of the two surfaces and the resistance of the body of the plate, which latter is proportional to the thickness of the plate. It is probable also that the resistance of the surface differs with the nature of the body or medium with which it is in contact. Thus a very rough surface on a metal plate would be likely to transfer more heat to adjacent air than a smooth surface would, since it has a greater area in actual contact with the air, while two rough surfaces of metal touching each other would transmit from one to the other less heat than two smooth surfaces."

He has computed the figures for heat resistance of several insulating substances from the figures of conducting power given in a table published by Mr. John E. Starr, in a paper on "Insulation for Cold Storage," published in "Ice and Refrigeration" for November, 1901. Mr. Starr's figures are given in terms of the British thermal units transmitted per square foot of surface per day per degree of difference of temperature of the air adjacent to each surface. The author's figures, the coefficients of heat resistance, given in the second column of the accompanying table, are calculated by dividing Mr. Starr's figures by 24, to obtain the hourly rate, and then taking their reciprocals.

"Analyzing some of the results given in the last column of the table, we observe that, comparing Nos. 2 and 3, 1 inch added thickness of pitch increased the coefficient 0.74; comparing Nos. 4 and 5, 1½ inches of mineral wool increased the coefficient 1.11. If we assume that the 1 inch of mineral wool in No. 4 was equal in heat resistance to the additional 1½ inches added in No. 5, or 1.11 reciprocal units, and subtract this from 5.22, we get 4.11 as the resistance of two ⅞-inch boards and two sheets of paper. This would indicate that one ⅞-inch board and one sheet of paper give nearly twice as much resistance as 1 inch of mineral wool. In like manner any number of deductions may be drawn from the table, and some of them will be rather questionable, such as the comparison of No. 15 and No. 16, showing that 1 inch additional sheet cork increased the resistance given by four sheets 6.67 reciprocal units, or one-third the total resistance of No. 15. This result is extraordinary, and indicates that there must have been considerable differences of conditions during the two tests."

HEAT CONDUCTING AND RESISTING VALUES OF BUILDING MATERIALS.

Brick Wall: Thickness.	Cond.	Res.	Revised. Res.	Revised. Cond.
4-in.	0.68	1.47	1.50	0.667
8-in.	0.46	2.17	2.30	0.435
12-in.	0.32	3.03	3.10	0.323
16-in.	0.26	3.85	3.90	0.256
20-in.	0.23	4.55	4.70	0.213
24-in.	0.20	5.00	5.50	0.182
28-in.	0.174	5.75	6.30	0.159
32-in.	0.15	6.67	7.10	0.141

40-in.	0.115	8.70	8.70	0.115

Wooden beam construction, planked over or ceiled:	Cond.	Res.
As flooring	0.083	12.05
As ceiling	0.104	9.71
Fireproof construction, floored over:		
As flooring	0.124	8.06
As ceiling	0.145	6.90
Single window	1.030	0.97
Single skylight	1.118	0.89
Double window	0.518	1.93
Double skylight	0.621	1.61
Door	0.414	2.42

The author has also calculated the coefficients of heat resistance from the heat transmission figures of various building materials, as given by Mr. Alfred R. Wolff, based on German experiments. These values are reproduced in a table herewith, the first column giving the conductance, in British thermal units per hour, and the second, the reciprocals, or heat resistances. It will be noted that there is an irregularity of the differences in the value of the resistance for each increase of 4 inches in thickness of the brick walls, which the author holds to indicate a difference in the conditions of the experiments. He finds the average difference is 0.80 and that the approximate formula for the resistance is $0.70 + 0.20\ t$, in which t is the thickness in inches. In the third and fourth columns are given the revised values of the resistance and conductance, respectively, ascertained in accordance with his formula.

The Cleveland Water Works Tunnel under Lake Erie is nearing completion, the work still to be done being the cleaning of recently finished sections and repairing of 300 feet of poor construction. Over 60 lives have been lost on the work, the last casualty being an explosion Dec. 14, which killed three men and injured others.

HEAT CONDUCTING AND RESISTING VALUES OF DIFFERENT INSULATING MATERIALS.

	Conductance.	Resistance
1. ⅝-in. oak board, 1-in. lampblack, ⅞-in. pine board (ordinary family refrigerator)	5.7	4.21
2. ⅞-in. board, 1-in. pitch, ⅞-in. board	4.89	4.91
3. ⅞-in. board, 2-in. pitch, ⅞-in. board	4.25	5.65
4. ⅞-in. board, paper, 1-in. mineral wool, paper, ⅞-in. board	4.6	5.22
5. ⅞-in. board, paper, 2½-in. mineral wool, paper, ⅞-in. board	3.62	6.63

19. Four double ⅞-in. boards (8 boards), with paper bet. three 8-in. air spaces	2.70	8.89
20. Four ⅞-in. boards, with three quilts of ¼-in. hair bet. papers separating boards	2.52	9.52
21. ⅞-in. bosrd, 6-in. patented silicated strawboard, finished inside with thin cement	2.48	9.68

High Pressure Steam Piping.

Abstract of a paper read by Mr. William Andrews before the Engine Builders' Association of the United States.

The art of piping for high pressure steam is of legal age. Twenty-one years ago, when Edison, at Menlo Park, brought out his electric lamp and called upon the engine builders, boiler makers and steam fitters to assist him with better apparatus, 80 pounds steam pressure per square inch on the boiler was considered good practice. It is true that higher pressures had been used on steamboats and locomotives, but the majority of stationary engines used in factories and mills were slow speed engines, piped with ordinary merchant pipe and screwed fittings, put up by any one who could use pipe tools. Soon all this was changed for the better, high speed engines were introduced, pressures were raised, fittings and valves were made much heavier and put up with some regard to expansion and contraction.

About the year 1890 high speed, compound non-condensing engines were installed in the central station of the Edison Electrical Illuminating Company, of Brooklyn. This was the first prominent installation of engines of this type and the specifications called for a steam pressure of 150 pounds. The pipe specifications called for flanged fittings and full weight special pipe, all to stand a working pressure of 150 pounds. There were no patterns for such fittings among the eastern manufacturers, and presumably, none among the western foundries. At any rate the fittings were made to order from special patterns and they are carrying steam to-day at full pressure. In this station was introduced the "double system" of piping which became a fad for a few years, but like the American buffalo, has almost become extinct.

About this time copper pipe became popular for high pressure work, probably on account of the ease with which it could be bent and formed into curves, which were just coming into fashion, but after a few years of use, having proved itself a very treacherous metal, it was discarded and now is very seldom used except for expansion bends in exhaust pipes. About 1892 wrought steel piping made in the regular way had become so reliable that it was used in making bends and steam mains, and at the present time is so generally used, that if an engineer wishes wrought iron pipe, especially in the larger sizes, he has to call for it in his specifications and then wait for it to be made. Pipes, fittings, valves, pumps, engines and all material used in a modern, first-class job, are now required to stand a working pressure of 200 pounds per square inch.

Strange to say that during the development of the electric light and railroad interest, almost the entire efforts of the engineers and owners were given to improving the engines, boilers, generators, heaters and pumps to the exclusion of the piping. So far was this carried that it was no uncommon thing for the owner, after the above mentioned articles were bought, and his attention was called to the piping, to say, "Piping! Oh, don't worry about that I will let my plumber put that up." It may not be out of place here to name the engineers, who, during the dark days of high pressure piping, always called for and insisted on the best. They were: William Lee Church, Frederick Sargeant, Charles E. Emery, J. H. Vail, E. J. Cooke and J. Van Vleck.

A modern high pressure steam job requires: First, a good design; second, good material, and third, skillful steamfitters. The first requirement can be altered to suit the conditions, but the other two, never. Up to the year 1900 the almost universal design for a piping system for power plants was to carry a pipe from each boiler into a large steam header, whose cross section was equal to the sum of all the areas of the feeding pipes. If the designing engineer wanted to be very grand, he made it larger without knowing just why. From this header, pipes were carried to the various engines, of sizes called for by the engine builder. It was quite common to place steam separators in each line leading to an engine, but fashions changed in steam piping, as well as in clothes, and with the advent of high pressure and superheated steam, sizes of pipes have been very much reduced. In the four large power houses now built in New York City, with an ultimate capacity of from 60,000 to 100,000 horse power each, the largest steam mains are not over 20 inches in diameter, and these are used more as equalizing pipes than storage reservoirs.

Some of our best plants have pipes which run from the header to the engine two sizes smaller than that called for by the engine builders. These pipes before reaching the engine are carried into a wrought iron or steel receiver, which acts also as a separator. This receiver has a cubical capacity of three times that of the high pressure cylinder, and is placed as near as possible to the cylinder. The pipe from the receiver to the cylinder is of full size called for by the engine builder. The object of this arrangement is, first, to have a full supply of steam close to the throttle, second, to provide a cushion near the engine on which the blow caused by the cut-off in the steam chest may be spent, thereby preventing vibrations from being transmitted through the piping system, and third to produce a steady and rapid flow of steam in one direction only, by having a small pipe leading into the receiver. This steam flows rapidly enough to make good the loss caused during the first quarter of the stroke. Plants fitted up in this way are successfully running where the drop in steam pressure is not greater than 4 pounds, although the engines are five hundred feet away from the boilers. This is probably the most radical departure in high pressure work up to the present time. Allowance for contraction and expansion is provided for by long bends, by using a double swing like a gas bracket on which the fittings turn on the threads of the nipple, and by producing what may be called initial tension. This can hardly be described in words, but is a rule of thumb method by which the skilled steamfitter puts a strain on the pipes when cold, so that when the pressure is put on, the expansion removes this tension and there remains no strain on the pipe, other than that due to internal pressure.

As to quality of material, in the earlier days of electric light and railroad plants, owing to the difficulty of keeping the screwed joints tight, some engineers tried flanged cast-iron pipe for steam mains, but it was heavy and clumsy and sometimes cracked on account of the unequal expansion. Then came copper and this pipe, even when reinforced with steel wire wound around it, was found to be a treacherous metal. Flanged cast steel pipe was tried, but the difficulty of obtaining this free from blow holes barred it out. At present the material used is either wrought steel or wrought iron pipe, on which the flanges are either riveted, screwed or welded. In England and on the continent they weld a light flange to the end of the pipe and face it; it is pulled together when in use by a heavy steel or cast-iron flange, which had previously been slipped over the pipe very much as copper joints are made in marine piping.

In 1880 the New York Steam Company installed about six miles of steam mains under the streets of New York for power and heating purposes. All the joints in this pipe above eight inches in diameter were made by expanding the pipe into recesses in the flanges, and then beating the ends of the pipe over the edges of the flanges. This was done by machinery, and was well done, and at the time was considered a great improvement over threading or riveting, but in five years every joint had to be taken out on acount of leaks and threaded joints were substituted. These threaded joints lasted until 1895, when all the pipes were renewed with new mains having heavy wrought steel flanges welded on the pipe. These welded flanges when turned true in the lathe make the most workmanlike and perfect steam joints in use at the present time, and their cost alone prevents their general use. Corrugated copper gaskets placed inside the bolts and well pulled up will make a joint which will last as long as the fittings. When the owner's bank account is strong enough, ground joints without any gaskets are used. This makes a first class job, but the price is all but prohibitive.

Gate valves are almost exclusively used in high pressure work, as globe valves, especially in the larger sizes, would be very clumsy, and they would also make a pocket in the pipe. If gate valves are used often enough to keep them in good order, they will remain tight many years. One of the very necessary points of a first class piping job, and one, too, which is very often overlooked, is to have extra heavy fittings on the gauge, lubricator and high pressure drip connections. A break in one of these pipes, while it may not shut the station down, would cause great inconvenience and would be a nuisance until it was fixed.

Vibrations which often accompany the installation of high speed engines in our modern buildings are many times laid to the bad foundations or the unbalanced condition of the engine. In almost all cases it is not true, the vibrations come from the bad piping and can be and, in many cases, have been removed without touching the engine or foundations. There is no excuse at the present time for having a bad piping job and yet there is a great deal of bad piping done. Should the underlying principles of good piping, namely, good design, material and workmanship, be more strictly adhered to, much less of the present piping would have to be done over a second time. The present almost universal practice of asking for competitive bids and giving the work to the lowest bidder, is responsible for this state of affairs.

The List of Atlas Sheets prepared by the co-operative survey of New York has just been increased by the issuance of seventeen new ones. Nine of them cover portions of Wayne, Seneca, Tompkins, Cayuga, Ontario, Yates and Schuyler counties, and take in portions of lakes Ontario, Seneca and Cayuga, and the whole of Montezuma Swamp. Two of the sheets cover portions of the Thousand Islands, and two cover portions of the southeastern Adirondack region. Three are in the Hudson valley in the neighborhood of Newburgh, and one covers portions of Madison and Oneida counties. Each sheet is printed on paper 16½ by 20 inches. The scale is about 1 mile to 1 inch, and differences of elevation are indicated by figures and by contour lines of 20-foot interval printed in brown. All drainage, as streams, ponds, swamps, etc., is printed in blue; all cultural features, as roads, railways, houses, and the names upon the map, are printed in black. On the reverse of each sheet is a brief explanation of the map and its uses. These sheets are sold at 5 cents each, or $2 per hundred. All communications should be addressed to The Director, United States Geological Survey, Washington, D. C.

Electric Heating and Lighting in the Carnegie Residence, New York.

The water supply and drainage of the new residence of Mr. Andrew Carnegie, on Fifth Avenue and 91st Street, New York City, were described in the issues of The Engineering Record for July 5 and August 2, 1902, and in this article it is intended to give an idea of the electrical work, with particular attention to the electric heating apparatus. The most noteworthy feature of the wiring is in the multiplicity of its circuits, whereby a very convenient switch control of all parts is afforded. The great number of lights used is remarkable in a building of this size, there being over 1,200 in all, of which more than half are on the first floor. Electric heating is used for such household purposes as laundry work, warming food or water, etc., and is not to be confused with the house heating, which is entirely separate. It may easily be said of the electric heating installation that it is one of the largest, if not the largest ever made in a private dwelling.

The lighting is on a 200-volt three-wire system and is supplied from the street service. The neutral wires, except in the mains from the street, have twice the capacity of the outer legs. This provision was made so that if at any time it should be desired to install a private lighting plant in the building using a two-wire system, the same wires may be used, the neutral then to constitute one lead and carry as much current as the two outside wires, which together will form the other lead. The heating and power circuits are on ordinary two-wire systems. The power circuits for each motor are taken individually from the main switchboard in the cellar. The mains from the street to this switchboard are 70 feet long and are of these sizes: 1,000,000, 500,000, and 1,000,000 circular mils.

The switchboard is of marble 2 inches thick supported by an angle iron frame. On the back of the board there are two bus-bars for power, three for light and four for heating. In cross-section the bars are proportioned by the rule of 1 square inch per 750 amperes of current carried. Connecting surfaces between bars and lugs allow but 500 amperes per square inch of contact. The switches include, one for the feeder to each lighting panel-board on the different floors, one for each motor feeder, and one for both the high and low-voltage circuits used in the heating. It is also provided with the usual meters and fuses.

From the switchboard in the sub-basement there are 28 feeder circuits. Each of the motors has its own pair of feeders direct from the switchboard, as have all of the heating circuits that carry more than 10 amperes. The remainder of the heating and lighting circuits are taken from fused panel boards having separate feeders for each class of work. The panel boards are of slate, seven in number, and have a switch for each feeder and branch. One board in the basement controls the cellar and basement branch circuits including 30 for light and 3 for heat taps. The first floor lighting, except that for the ceiling lights in the art gallery, is controlled from two boards in the basement, one having 59 light taps and the other 22. The gallery panel board is on the first floor and has 29 light tap circuits all controlled by two three-pole single-throw 200-ampere switches. On the second floor there is a panel controlling that floor which has 30 light and 4 heat taps. The third floor has a board with 29 light and 5 heat taps; and the fourth floor, one with 8 light and 2 heat taps.

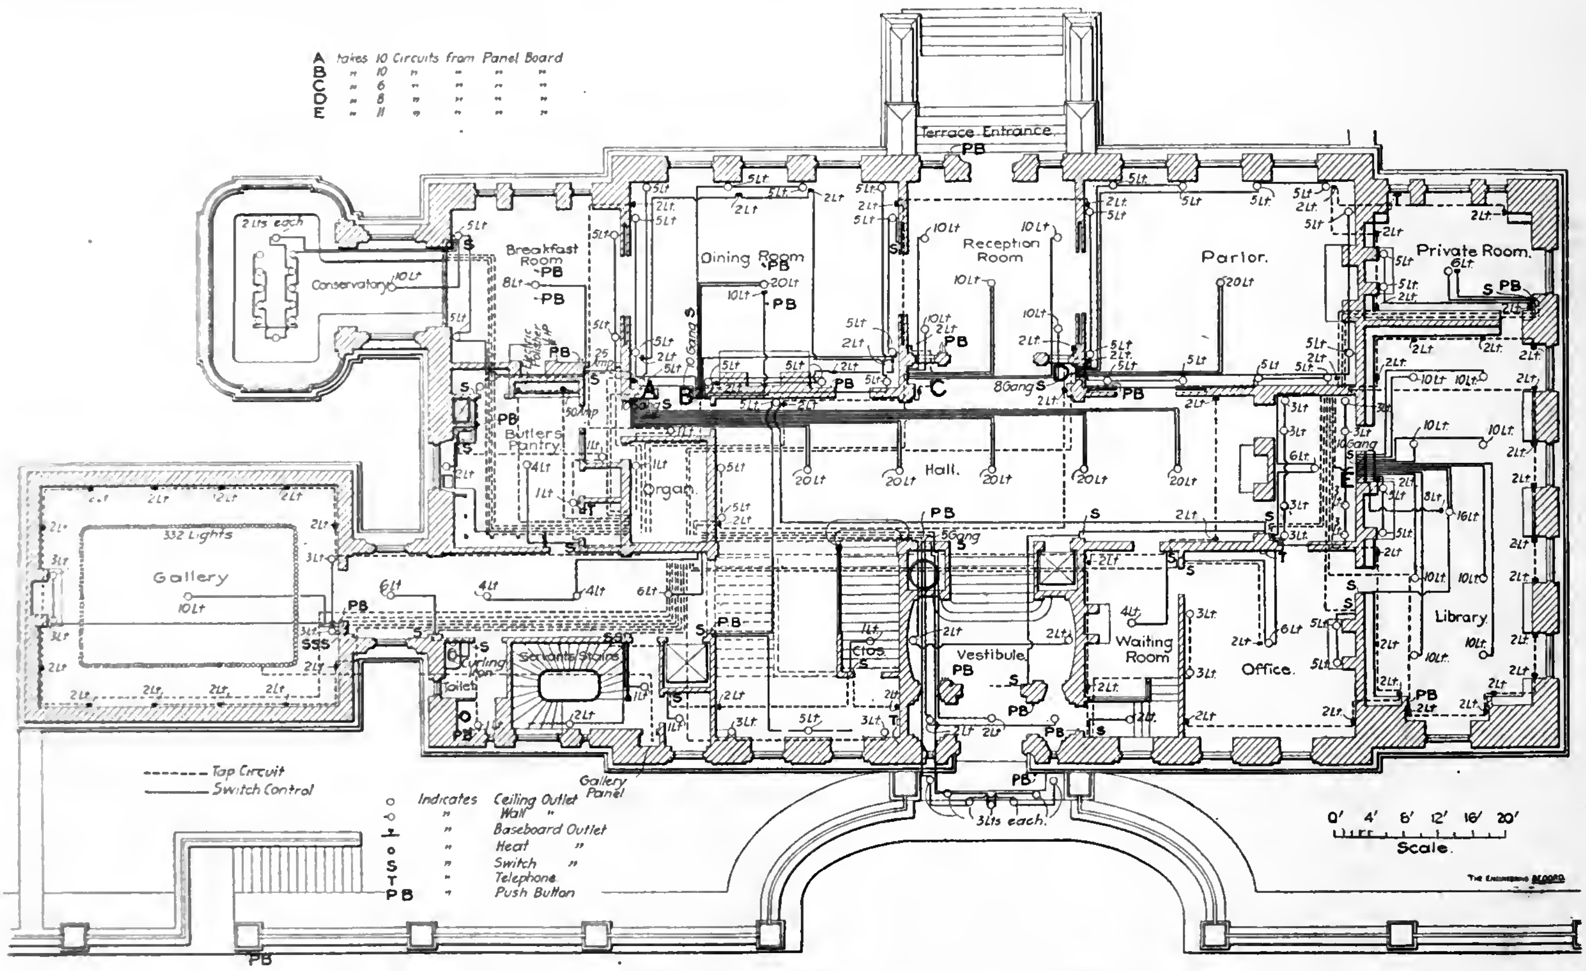
The feeders and all wiring from floor to floor are run in a wire-riser shaft located at about the center of the front of the house. All wiring is concealed and where carried in walls or ceilings is enclosed in insulated iron conduits. In most of the rooms, especially above the basement, there are two switches located near doors so that the lights may be lit or extinguished by the most convenient switch. Where desirable the lighting of one room or hall is on two or more circuits, making it possible to light the room partially or brilliantly. In such case a gang switch is usually installed to allow all of the lights to be extinguished simultaneously from one point.

A night service is provided for the halls and stairways throughout the house to burn a certain number of lights all night. A switch control for this system is afforded for each floor or it may be entirely cut off from the main switchboard. All wall switches are of the double-pole flush type and are placed four feet from the floor. There are 343 of these besides 17 carbon-break switches for the night service.

The wiring of the first floor is the most extended and is given on the accompanying plan. The localization of the lighting of the main hall and the large rooms which occur on this floor is shown in the five gangs as distinguished by the letters A, B, C, D and E. One noticeable feature to which attention has not been called thus far is the provision of many outlets in the baseboards of rooms to afford convenient extensions, to suit, for example, any desired location of a portable or desk light. In the art gallery there are two circuits entirely used for these baseboard outlets, which will enable a particular lighting to be given to any certain picture.

The other figure given is a riser diagram showing merely the run of the main distributing feeders and includes the power and heat lines as well as those for the lighting. A little idea of the extent of the wiring may be obtained when it is considered that in the feeders alone there is over a mile and a quarter of wire, which would be a small part as compared to the total length of wire if all of the branch circuits were included.

There are no steam pumps used at all in the building, and, with the exception of one Rider hot-air engine, all power is supplied by motors.

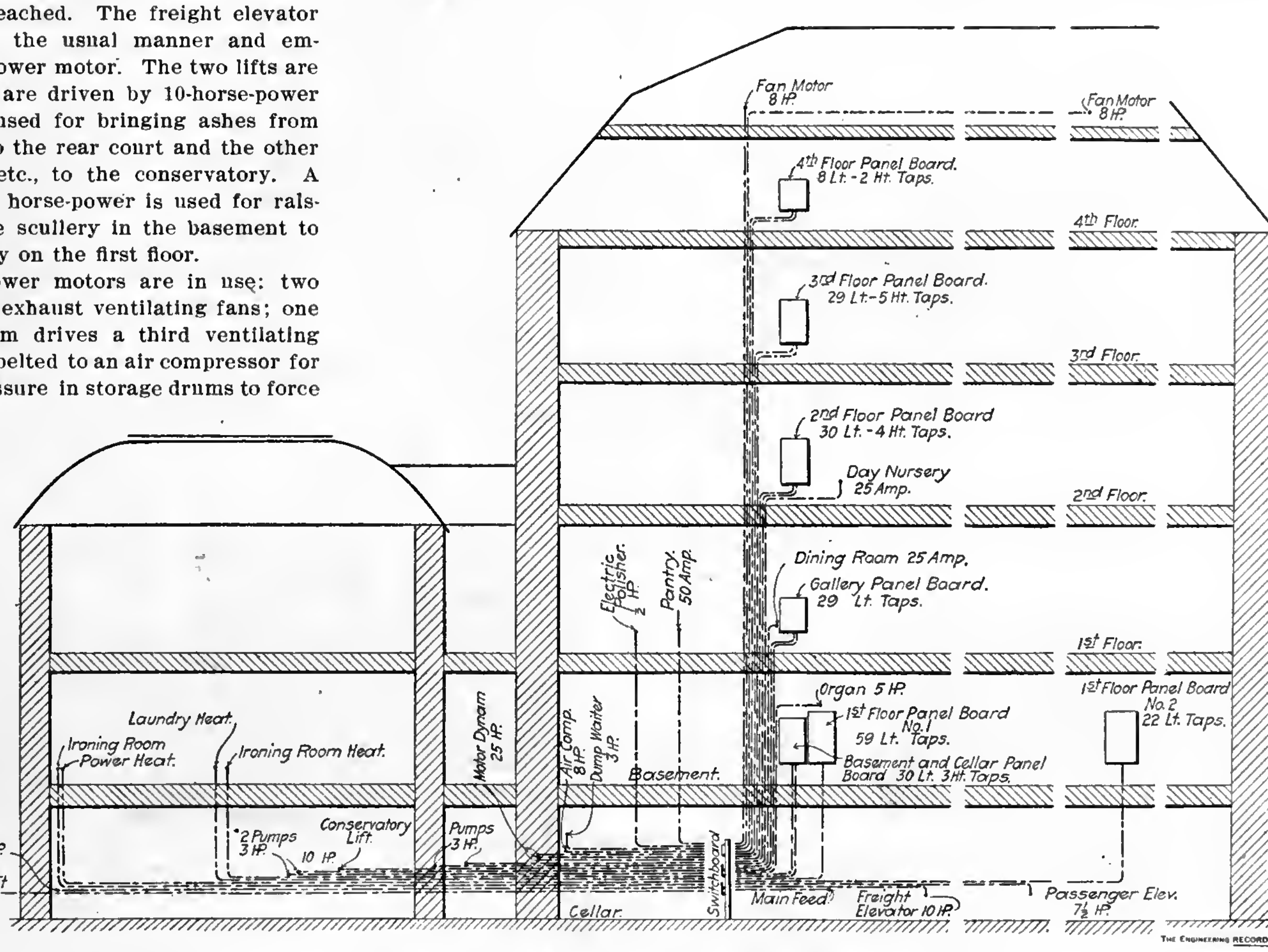


PLAN OF FIRST FLOOR WIRING, CARNEGIE RESIDENCE, NEW YORK CITY.

The largest unit consists of a 25-horse-power motor-generator used in connection with the electric heating. It is of the Western Electric Company's make and embodies a 220-volt motor direct-connected to a 20-volt dynamo which delivers a correspondingly increased current. The apparatus supplied at this reduced pressure is located in the laundry and ironing rooms, those being the only heaters that could not be run satisfactorily on the higher voltage.

The elevating machinery includes two elevators, two lifts and a dumb-waiter. The psssenger elevator is operated by a 7½-horse-power motor and has the automatic push button system of control. This is of the usual type, the person requiring its use pressing a button which causes the elevator to move to that floor and stop, if it is not already in use and the doors are all closed. After the occupant is within the car and both doors are closed, he presses the button corresponding to the floor to which he would go and the motor starts up in the required direction stopping when the indicated floor is reached. The freight elevator is operated after the usual manner and employs a 10-horse-power motor. The two lifts are of short run and are driven by 10-horse-power motors. One is used for bringing ashes from the boiler room to the rear court and the other to raise plants, etc., to the conservatory. A dumb-waiter of 3 horse-power is used for raising food from the scullery in the basement to the butler's pantry on the first floor.

Four 8-horse-power motors are in use: two in the attic drive exhaust ventilating fans; one in the boiler room drives a third ventilating fan; the fourth is belted to an air compressor for establishing a pressure in storage drums to force filtered water to the various parts of the house. The blower for the pipe organ in the chapel or music room on the first floor is located in the basement and is driven by a 5-horse-power motor. The water pumps are each direct-driven by a 3-horse-power General Electric motor. Two, of the Quimby rotary type, are for the hot and cold water house service and two centrifugal pumps are for emptying a sewage tank. The last and smallest motor is a ½-horse-power motor located in the butler's pantry and used for running a buffer for polishing silver.



RISER DIAGRAM OF ELECTRIC FEEDERS.

The electric heating apparatus was all made in special patterns to accord with the specifications furnished by the engineers and includes the following: Three flat iron heaters, one for 10 irons and two for 2 irons; three stoves, one with 2 lids and two with 1 lid; a starch boiler; a clothes boiler; a plate warmer for warming dishes; and a heated plate for keeping food hot until ready for serving. All of the apparatus is supplied on a two-wire 220-volt direct-current service, with the exception of the ten-iron heater, starch and clothes boilers and a one-lid stove, which are on the 20-volt system previously mentioned. Where movable the apparatus is provided with a marble base and is connected with the current outlets by flexible leads. The outlets are taken from panel boxes with D & W enclosed fuses in both leads or else fuses are provided in the apparatus itself.

The ten-iron heater, in the ironing room in the basement, is mounted on a fixed iron stand and occupies a floor space of 56x14 inches. The top consists of an iron frame in which a row of ten contiguous heating plates is set, each 5x7 inches in area and ½ inch thick. The size was determined on a basis of using from four to nine-pound flat irons. It has been found that 15 irons of the sizes most commonly used can easily be heated at one time when all of the ten plates are working, and that for ordinary usage a great plenty may be kept hot by the use of only 5 plates. Each plate is individually supplied with current and controlled by a two-pole snap switch placed in the front panel of the heater. With the 20-volt service used the required heat for a single plate is obtained by a current of 40 amperes, making the total maximum capacity 400 amperes and the consumption 8,000 watts. The plates heat up with remarkable rapidity and will heat a cold iron to its proper temperature in from 10 to 15 minutes according to its size. Starting with the plate cold the hand cannot be held on it for a full minute after the current is turned on. The regulation of the heat of an iron is commonly done on an ordinary range by pushing the iron to the back part of the stove when it is becoming too hot. Such regulation may be accomplished with this electric heater by turning current on but a few of the central plates and using the adjoining dead plates, which by conduction will have a decreasing intensity of heat as the distance from the live plates is increased.

The laundry adjoins the ironing room in the basement and contains the starch boiler, clothes boiler and a one-lid stove. The starch boiler is of the water-bath type and has a capacity of 5 gallons. The inner starch pan is of heavy hammered copper 15 inches in diameter and 7 inches deep. The water bath surrounding it is sufficiently larger to afford room for water in the bath and consists of a planished copper jacket with an upward recess for the heater in the bottom. The heater is insulated by a false bottom, and by its placing offers the greatest amount of heating surface possible to the water within the bath. Its construction is somewhat similar to that for the iron heater but it is divided into two separate circuits, by the use of which either full or half heat may be obtained. Full heat requires 160 amperes on 20 volts and is used while the starch is coming to a boil. After that time the half heat suffices to maintain the required degree of heat in the starch. The boiler occupies one end of an iron stand on the other end of which is placed the one-lid stove. This stove differs from the other stoves to be later described, in that it is on the 20-volt circuit and contains an irremovable heater. The heating material is divided into two circuits to give two degrees of heat. It supplies a means of heating water in small quantities or any other heating likely to be required by the laundresses.

The clothes boiler occupies an adjacent marble-top iron stand and consists of a large rectangular copper kettle with rounded corners and a cover. It is 23x33 inches overall and 24 inches deep and rests on a heating plate 20x30 inches. Attached to the lower side of the plate is the heater, in this case fitted for full and two-thirds heat, using, on 20 volts, a maximum current of 580 amperes with a maximum energy density per square inch of superficial area not to exceed 23 watts. Water is drawn cold into the boiler from a faucet close by and brought to a boil on the plate. For emptying the kettle a tap is provided near the bottom. The clothes boiler has a separate panel box with leads therefrom run in flexible coiled wire armoring finished in bright nickel. The starch boiler and one-lid stove are supplied from another panel box with similarly protected leads.

in the brush room in the basement there is a two-iron heater of the same general construction as the one for ten irons, but mounted on a marble base instead of an iron stand. It is operated on 220 volts instead of 20 and uses about 9 amperes when both plates are running. It will be used for pressing garments or other outside wearing apparel.

So much for the heating apparatus in the basement. The first floor contains but two pieces of like apparatus, both located in the butler's pantry. The first is a plate warmer and is the largest feature of this installation. It stands directly on the floor, is approximately 48 inches high, 40⅜ inches wide and 25 inches deep, and has an external casing of heavy Russia iron with two doors, latching at top and bottom and lined with the same material. The trimmings, such as hinges, latches, etc., are of nickeled and polished iron. The inner casing is of Russia iron of the same weight as the outer casing and is separated from it by an air space of 1¼ inches. The warmer contains three shelves, each the full size of the interior, framed with angle iron and covered with perforated iron. Heat is supplied by two circuits of coiled wire so wound on porcelain insulators that either circuit while running alone will give a uniform heat to the entire shelf. The insulators are mounted closely together on rigid cross bars and distributed over the entire surface, affording a strong support for the perforated sheet above them. Two degrees of heat, full and one-half, are supplied to each shelf, so that the complete interior may be subjected to six degrees of heat. Current is supplied on 220 volts with a maximum of 15 amperes, or 5 amperes to a shelf; half heat requiring but half those amounts. A double-pole flush switch controls each circuit of each shelf.

Located in a passage off from the butler's pantry, there is an electrically heated steam plate for warming food. It is in the form of a modified bain marie. The plate is 20x30 inches of heavy tinned copper and sets in a copper water bath so as to allow a space of 3 inches above water level with the water not over 2 inches deep. The heater is attached to the bottom of the water bath and insulated from it, being recessed into the bottom to give the greatest amount of surface to water contact. The heater is made in three sections with a flush switch for each, to allow of three different heats, using 6 amperes on 220 volts. A glass water level gauge, a cock for draining and a funnel for filling are fitted to the water bath, and a deep cover of heavy planished copper is provided to set over the whole to retain the warmth.

On the second floor in the nursery pantry, a two-lid stove will be used for water heating and limited cooking. The overall dimensions are 16x24 inches, and the two lids are each 8 inches in diameter. The stove is mounted on an ornamental iron stand, barffed a blue black color, with the usual marble base. Each lid has two flush switches mounted in the front panel giving independent control of each of two degrees of heat. The 220-volt pressure is used with a maximum current of 10½ amperes on both lids or 2¾ amperes on each heat. In this stove the lid and heater is a removable unit. The lower side contains lugs which engage in phosphor bronze contact clips and form the connections between the switch control and the heating medium.

The third floor heating apparatus introduces no features other than those already described. A two-iron heater precisely similar to the one in the brush room in the basement is found here in the sewing room, its purpose being, as before, to heat irons for pressing clothes. In one of the bath rooms there is a stove with one lid, but otherwise identical to the two-lid stove last mentioned. It is 16x16 inches overall, with iron stand, marble base, and switches for full and half-heat, each heat consuming 3 amperes at 220 volts. These two heaters and all of the smaller heaters except the laundry stove, are movable and may be disposed of in any convenient manner when not in use. Their connections to the outlets of the current source in the room baseboards are made by plugs on their leads.

In addition to the foregoing uses of dynamo current the residence is elaborately equipped with battery systems supplying call bells, telephones, etc. One battery of 12 cells, arranged 6 in series and 2 in multiple, operates bells and annunciators for all parts of the house. There are seven annunciators, the two largest being the one in the basement with 52 drops and the one in the butler's pantry with 24. The house has its own private telephone system with 21 instruments and 20 cells of battery for their operation, besides four telephones connected with the public service. In short the building embraces all of the now common conveniences that may be afforded by the use of electricity.

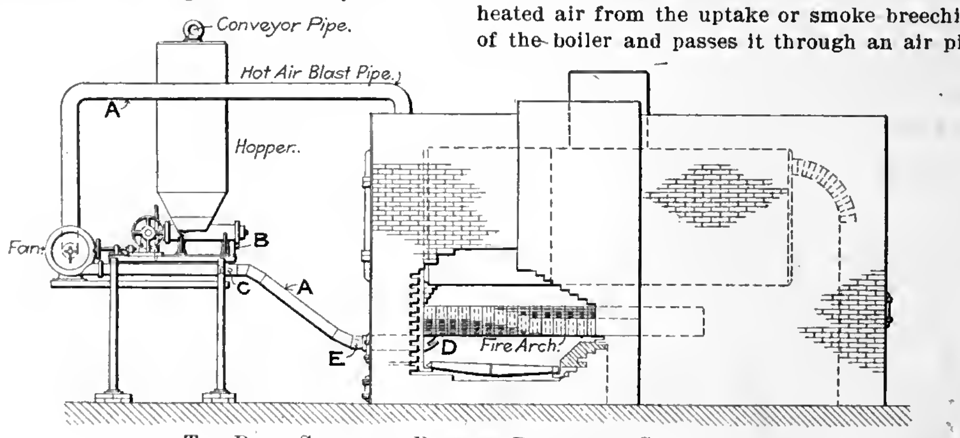
The building was erected from the plans of Messrs. Babb, Cook & Willard, of New York, and its electrical features were designed by the electrical engineers, Messrs. Clark & MacMullen, also of New York. The contractors were: For the electric heating, the Hadaway Electric Heating and Engineering Company; for the electric lighting and the switchboard, Mr. Charles L. Eidlitz.

Standard Bench Monuments in Chicago are built of granite concrete with the top of a hardened copper rod showing at the surface under an iron cover. The concrete extends 6½ feet below the surface of the ground, is 3½ feet square at the bottom, and 16 inches at the top, where it is 6 inches below the surface. An iron cover with movable lid protects the bench point. These monuments average about a mile apart each way, and according to the 1901 report of Mr. W. H. Hedges, bench and street grade engineer, about half the city has been provided with them. In running the lines of exact levels to determine the elevations of these concrete monuments, there were established at the same time 935 bench marks of the ordinary kind along these lines of levels, choosing the best points available for that purpose, viz., stone or iron door-steps, water-tables of buildings, corners of stone or cement curbs, roots of trees, tops of hydrants, etc. These ordinary benches are not reported to the city council for confirmation, and are in no way official in their character, but are simply recorded in the city bench books for the convenience of the engineers employed by the city and of any city surveyors who may wish to copy and make use of them.

The Rowe System of Burning Pulverized Coal.

In view of the increased attention that has been given during the past couple of years to the burning of pulverized coal under steam boilers, a device for this purpose, known as the Rowe feeder system, that has been perfected and put into practical operation by the C. O. Bartlet & Snow Co., of Cleveland, Ohio, will doubtless be of interest. Among the advantages of burning pulverized fuel might be mentioned practically perfect combustion and the consequent absence of smoke, a considerable saving of fuel on account of the readiness with which the air supply can be adjusted and the reduction of the ashes and refuse to a minimum. The designers of the apparatus maintain that in order to obtain perfect combustion three conditions are absolutely necessary; that the coal must be of uniform size, that it must contain the minimum amount of moisture and that the powdered coal must be burned while suspended in the air.

The system as applied to the boilers in the company's works is shown in the accompanying illustration. It is being used with the cheapest kind of bituminous slack. This is dried so that it will not contain over 2 per cent. moisture and then ground so as to pass an 80-mesh sieve, making it practically dust. The dust is stored in an iron storage hopper or tank near the boiler. A blower of sufficient size to furnish the necessary air for burning the coal draws heated air from the uptake or smoke breeching of the boiler and passes it through an air pipe A to the furnace. Coal is conveyed by a special conveyor from the bottom of the storage bin to a spout B. The speed of this conveyor controls the amount of coal used, which can be changed at a moment's notice by turning a hand wheel. From the conveyor the coal is fed directly to the air spout A. There is a nozzle C on the inside of the air spout which converges the current of air just as it strikes the coal falling from the conveyor. This insures a thorough mixture of the two and at the same time prevents clogging. The coal is blown by the current to the furnace spout, but just before entering this the mixture passes through another nozzle E which again mixes the air with the dust. The feed spout is made of cast-iron and has a semi-circular opening or mouth so as to spray the coal dust upward against an arch wall, where it is ignited and burned. This spout is covered with fire brick for protection and the current of air continually passing through it also protects it from burning out. In fact, there is nothing about the system which is not durable, an important feature in any system. There are slides or valves in the air pipe so as to admit just enough air to obtain perfect combustion. Attention is called to the fact that the application of this device to a steam boiler requires practically no change in the grates and in case of an accident coal can be fed through the furnace doors. With the apparatus it is not necessary to open the furnace doors, thus admission of cold air is prevented.



The Rowe System of Burning Pulverized Coal.

The Water Supply of King's Lynn, England.

The borough of King's Lynn has a population of about 20,000. Its old water supply, drawn from a small tributary of the Ouse River, was badly polluted and an outbreak of typhoid fever due to this cause led to the installation of a new supply in 1899, under the direction of Mr. E. J. Silcock, M. Inst. C. E. The new works, which cost about $150,000, consist of two wells about 6 feet in diameter and 100 feet deep with three horizontal headings at the bottom, a covered reservoir and nearly 7½ miles of 15-inch cast-iron mains. The whole scheme was described at length some time ago in an article by Mr. F. C. Grimley in "The Surveyor," from which the following account has been condensed:

The wells are sunk in the hard chalk about eight miles from Lynn, and are 14 feet apart center to center, 6 feet 2 inches in diameter and 100 feet deep, with a lining of concrete varying in thickness from 14 inches at the top to 6 inches at the bottom. The concrete was composed of 1 part cement to 4 parts of gravel and sand. Circular moulds 6 feet 2 inches in diameter and 3 feet deep were used for placing the concrete in position as the excavation proceeded. From the bottom of the western well two headings, 6 feet high and 4 feet wide were driven, one to the south 153 feet long and the other to the north 213 feet long. Another heading which was commenced in an easterly direction from the eastern well had only proceeded 50 feet when it was found that the quantity of water required (1,000,000 imperial gallons a day) could be procured. The east heading was, however, extended to a total length of 293 feet and a bore-hole 8 inches in diameter and 63 feet deep was put down in the east well, passing into the sand below the chalk formation.

The output of the wells was tested by continuous pumping for a fortnight, the water passing into a concrete tank where gaugings were taken at frequent intervals. The quantity of water finally obtained was 1,250,000 imperial gallons per day at the most unfavorable time of the year and after a prolonged drought. The supply since the works were put in operation has been greatly in excess of the demand, which in March, 1901, was about 650,000 gallons a day. The bottom of the wells is 32 feet above ordnance datum, and the water stands at a height of 70 to 80 feet above ordnance datum when pumping is not going on. The engine is erected over the wells. Rails are set in the side walls at a height of 10 feet, on which runs a traveling crane for the hoisting of machinery when necessary. The engine for each well is placed at one side of it, a good foundation being afforded by the chalk, which is very near the surface. Between the two engines a flight of stone steps descends to a subway lined with white glazed tiles, the bottom of which is 16 feet below the floor of the engine house. This subway communicates with both wells, and inside of each of them at this level is fixed a permanent staging. This is the lowest point to which the engineer in charge needs to go in the ordinary course of working, everything below this depth being arranged to work automatically. The subway is arched over so as to provide a shelf upon which the delivery pipes unite with the rising main.

The pumping plant is in duplicate, consisting of two sets of boilers, engines and pumps, each capable of delivering 1,000,000 imperial gallons per day through 18,730 feet of 15-inch pipe, against a head, including friction of 123 feet. The different portions of the plant are interchangeable, being so arranged that either of the boilers will supply steam to either or both engines, and each engine will drive the pumps in either well. The possibility of a breakdown is further provided against by each set of pumps, consisting of three, being worked by equidistant cranks on the same axle. One or more of them, therefore, can be withdrawn for repairs while the others remain at work, so that before a complete stoppage can occur it will be necessary for six pumps, two engines, or two boilers to fail simultaneously.

When pumping ceases the water in the wells rises rapidly to a height of about 50 feet, so that the working portions of the pumps, which are within 20 feet of the bottom of the wells, are submerged. All portions of the pumps are attached to a massive iron staging fixed in the well just above the high-water mark, so that it is not necessary to pump out the water either for fixing the machinery or in case of repairs being afterwards required. In addition, this staging forms a water-tight floor, and so effectually prevents the possibility of any oil or dirt from the machinery getting into the water in the well. The pumps are of the three-throw type. The working barrels and parts are of gun-metal, and all the large pipes which are 13 inches in diameter, are of steel plate, electrically welded and afterwards galvanized, thus securing lightness, strength and freedom from rust. At a point above the pump stage the three tubes unite into a single main, and the pipe from each well joins the rising main upon the shelf before described. The engines are of the horizontal, compound, triple-expansion type. They are designed for a working boiler pressure of 140 pounds per square inch, and have lately been arranged so as to run coupled together and work both sets of pumps. While running coupled together, the speed of the engines is from 75 to 80 strokes per minute, but when running separately the normal speed is from 112 to 120 strokes per minute.

As a result of a series of tests it was found that the engines could pump the total quantity required, but the slip of the pumps was somewhat excessive, being 7 per cent. The west engine gave an efficiency of 21.3 pounds of steam per hour per pump horse-power, and the east engine 21.5 pounds. The west boiler gave an evaporation of 10.25 pounds of steam per pound of coal and the east boiler 9.55 pounds. The length of stroke of the engines is 14 inches and the diameter of cylinders 6¼, 9¼ and 12½ inches. The pump cylinders are 12½ inches in diameter and have a stroke of 2 feet 6 inches, being geared to make one stroke to six of the engine.

The water is pumped through about 3½ miles of 15-inch cast-iron pipes to the service reservoir, which is 140x100 feet in size. The main follows the contours of the roads at a depth of about 4 feet from the surface. The top water-level of the reservoir is 139 feet above ordnance datum. The subsoil consists of boulder clay to a considerable depth. Excavations were first made to a depth of 6 feet, and on the bottom was laid a floor of concrete 18 inches thick, increasing to 3 feet 6 inches at the bases of the columns which support the roof. The floor is composed of a series of inverted arches springing from the bases of the columns, and it has, in common with the walls, a 4½ inch lining of bricks set in Portland cement. The walls are built of concrete, composed of cement 1 part, sand 2 parts and shingle 4 parts. They vary in thickness from 5 feet to 18 inches, the total height being 14 feet. Rows of 18-inch brick columns 10 feet apart center to center support the roof, which is composed of 4½-inch brick arches carried by cast-iron girders 12 feet long. These girders run the short way of the reservoir, and are tied in with 1¼-inch tie rods. The spandrels of the arches are filled with concrete, and the whole is covered with ½ inch of asphalt.

For the purpose of cleansing, the reservoir is divided into two equal parts by a brick wall 6 feet high. When the water is level with the top of this wall, there are 250,000 imperial gallons in each half, which is a quarter of the total capacity. At the north end of the division wall is fixed an electrical indicator, communicating by wire with the pumping station, so that the engineer on duty is informed of the rise or fall of the water in the reservoir. This appliance also records the variations in the height of the water upon a chart, thus giving a permanent record.

The length of the delivery main to the East Gates of Lynn is nearly 4 miles, from which point the water is distributed through the same mains which were in use before. The cost of the most important items in this work was as follows: Two engines with boilers, $15,900; wells and headings, $8,400; buildings, $17,900; pipe line, $66,200; reservoir, $25,400.

Personal and Obituary Notes.

Mr. Alphonzo Tarr has been appointed water commissioner of Gloucester, Mass.

Civil Engineer L. M. Cox, U. S. N., has been ordered to leave Guam for the United States.

Mr. Michael B. Corriden has tendered his resignation as superintendent of the Logansport, Ind., water-works.

Mr. Francis D. H. Lawlor, M. Am. Soc. C. E., has been appointed superintendent of the Burlington, Ia., water-works.

Mr. F. M. Webb is said to have resigned as mechanical engineer of the London & Northwestern Railway, England.

Mr. Edward DeV. Tompkins has been appointed assistant engineer in the Department of Bridges, New York City.

Messrs. Thomas Murray, John E. Moore and Henry Nagel were reelected city engineer, city electrician and street commissioner, respectively, at Davenport, Ia.

Messrs. Cope & Stewardson, of Philadelphia, on the basis of a competition, have been appointed architects for the municipal building for the District of Columbia.

Mr. Robert L. Warner, Boston sales manager of the Westinghouse Electric & Mfg. Co., presented a paper on electrically driven shops at a recent meeting of the New England Railroad Club, at Boston.

Mr. C. E. Fowler, president and chief engineer of the Puget Sound Bridge & Dredging Co., read a paper before the Pacific Northwest Society of Engineers at Seattle, December 6, on the corrosion of iron and steel.

Mr. T. L. Lyman, manager of the Asbestos Department of the H. W. Johns-Manville Co., New York, sailed December 20 for Havana, Cuba, where he will remain about two weeks for the benefit of his health.

Mr. J. W. Peterson has been elected president and general manager of the Electrical Equipment Co., contracting engineers, Monadnock Block, Chicago, succeeding Mr. J. Holt Gates, who has retired from the company.

Mr. H. F. J. Porter, of the Bethlehem Steel Co., delivered the founder's day address at the Clarkson School of Technology, at Potsdam, N. Y., December 1. His subject was: "Technical Education and the Higher Industrial Life."

Miles Leonard, a well-known contractor of New York State, died December 11 at his home in Binghamton, aged 52 years. He erected many of the prominent buildings in that city and was contractor for the Manhattan State Hospital at Central Islip.

Mr. Burton J. Ashley, whose retirement as chief engineer in the founding of Zion City, Ill., and resumption of private practice in Chicago was announced November 29 has established his offices in The Temple, Chicago. He reports 8,000 persons in Zion City at the end of 16 months.

Among the recent railroad appointments are the following: Mr. C. P. Chamberlain has been appointed division engineer of the Chicago Great Western Railway at Des Moines, Ia. Mr. L. G. Haas has been appointed assistant general manager of the Baltimore & Ohio Railroad succeeding Mr. Arthur Hale, who has become general superintendent of transportation, and his position as general superintendent at Pittsburg is to be filled by Mr. I. G. Rawn, general superintendent, at Cincinnati, of the Baltimore & Ohio Southwestern Railroad. Mr. R. C. St. John has been appointed assistant chief engineer of the Michigan Central Railroad with headquarters at Detroit.

At its meeting last week in New Orleans, the following committees of the American Public Health Association were announced: Purification of Public Water Supplies: George W. Fuller, New York City; Robert S. Weston, Boston, Mass.; H. W. Clark, Boston. Disposal of Industrial Wastes: Dr. G. T. Swarts, Providence, R. I.; Allen Hazen, New York City; Prof. L. P. Kinnicutt, Worcester, Mass. Purification and Disposal of Sewage: George H. Benzenburg, Milwaukee, Wis.; J. W. Alvord, Chicago, Ill.; J. P. Force, Columbus, O. Disposal of Garbage: Rudolph Hering, New York City; Elzear Pelletier, Montreal; W. C. Woodward, Washington, D. C. The bacteriological section elected the following officers at its meeting last week in New Orleans: Chairman, Dr. H. L. Russell, Madison, Wis.; vice-chairman, Dr. Veranus A. Moore, Ithaca, N. Y.; secretary, G. C. Whipple, Brooklyn, N. Y.; recorder, Dr. H. D. Pease, Albany, N. Y.

The American Institute of Architects, at its meeting in Washington last week, approved the following additions to membership and elected the following officers: Honorary members: Andrew Carnegie, Pittsburg, Pa.; Samuel A. D. Abbott, Boston, and Emil Neuchamer, Paris, France. Corresponding members: George R. Shaw, Boston; John James Burnett, Glasgow, Scotland; Banister F. Fletcher, London, Eng.; Mervin McCartney, London, Eng.; Leonard Stokes, London, Eng.; William R. French, Chicago; A. H. Bloomfield, London, Eng. Fellows: W. R. Mead, New York; G. L. Heins, New York; R. A. Cram, Boston; Elmer Grey, Milwaukee, Wis., and J. L. McGrann, St. Louis. Officers: President, Charles F. McKim; first vice-president, Frank Miles Day; second vice-president, Alfred Stone, and secretary-treasurer, Glenn Brown. Board of directors: Robert S. Peabody, William B. Mundie, Isaac C. Ditmars. Auditing committee: S. A. Treat, Wm. G. Preston.

The Removal of Garbage in Chicago was done during 1901 at a cost of $490,302, the amount removed being 1,333,920 cubic yards, giving as the cost per cubic yard about 36¾ cents. A portion of the amount removed had to be hauled from 8 to 10 miles, and the Commissioner of Public Works, Mr. F. W. Blocki, recommends the erection of garbage reduction plants along the banks of the Chicago River, so that garbage may be carried to them in scows.

CONTRACTING NEWS

OF SPECIAL INTEREST TO

CONTRACTORS, BUILDERS, ENGINEERS AND MANUFACTURERS

OF ENGINEERING AND BUILDING SUPPLIES.

For Proposals see pages 21, 23, 24 and 36.

WATER.

Lowell, Mass.—R. J. Thomas, Supt. of Water Wks., writes that the State Legislature has passed a bill enabling this city to lay pipes and supply city water to the inhabitants of Chelmsford and Dracut. The matter is now pending action of the Lowell city government.

Weymouth, Mass.—See "Power Plants, Gas and Electricity."

New London, Conn.—The Water Comrs. have voted to secure a tract of land on Mohegan Ave. on which to build a distributing reservoir, having a capacity of 350,000 gal.

Great Barrington, Mass.—City Engr. Curtiss is said to have completed profiles of a 40-ft. dam at Goodale Brook.

Amherst, Mass.—The Amherst Water Co. has petitioned Legislature for permission to acquire certain water rights and lands in the town of Shutesburg; the Co. also desires to increase its capital stock and to issue additional bonds.

Allentown, Pa.—City Engr. J. Howard Martz writes that the proposed gravity water works system will probably cost $200,000.

Troy, N. Y.—The contract for furnishing all material (steel pipe will be used) and constructing the conduit line of Tomhannock extension of Troy water works system is stated to have been awarded by the Board of Contract & Supply to the T. A. Gillespie Co., of New York, at $259,300. For detail bids see The Engineering Record of Dec. 13.

McKees Rocks, Pa.—Local press reports state that Ch. Engr. J. A. Atwood, of the Pittsburg & Lake Erie R. R., has awarded contracts for additional improvements at McKees Rocks as follows: To Dravo Const. Co., sinking well and building a pump house for $20,000; to N. F. Trimble & Sons, contract for superstructure of new erecting and machine shop, 560x170 ft., for about $130,000. It is stated that a contract will soon be let for pumps and machinery, to cost $5,000, for the water works plant.

Gloucester City, N. J.—The City Council has passed on its second reading an ordinance for the issue of water works improvement bonds. It is proposed to reconstruct the reservoir, and install an air compressor plant at a probable cost of about $15,000.

Brooklyn, N. Y.—Bids will be received until Dec. 30 for furnishing, delivering and laying water mains in portions of several streets in the Boro. of Brooklyn. Robt. Grier Monroe, Comr. of Water, Dept. of Water Supply, Gas and Electricity, N. Y. City.

Long Island City, N. Y.—Bids will be received until Dec. 30 by Robt. Grier Monroe, Comr. of Water, Dept. of Water Supply, Gas & Electricity, N. Y. City, for furnishing, delivering and laying water mains in portion of several streets, in the Boro. of Queens.

New York, N. Y.—Bids are wanted Dec. 30 for furnishing and installing superheaters, furnaces and all appurtenances in the pumping stations at 98th and 179th Sts., Boroughs of Manhattan & Bronx. Robt. Grier Monroe, Comr. of Water, Dept. of Water Supply, Gas & Electricity.

Baltimore, Md.—The Comn., which is to select a site for the new storage reservoir provided for in the ordinance of estimates for 1903, is composed of Mayor Hayes, Water Engr. Quick and City Comptroller Smith. Said Comn. will have $350,000 with which to purchase land for the reservoir and begin work of construction.

Wilmington, Del.—A site has been purchased by the Bd. of Water Comrs. for a city water plant. The Comrs. contemplate building two basins, one to hold 100,000,000 gal. and the other from 5,000,000 to 10,000,000 gal., and a filter plant. No plans have been drawn for the plant, and it has not been decided what filter system will be used.

East Orange, N. J.—The Water Com. is taking steps relative to the execution, with the Orange Water Co., of a contract for a water supply for one year. The Water Com. of the City Council has decided to engage an engineer to work in conjunction with City Engr. W. H. V. Reimer to prepare plans and specifications for a distributing system.

Binghamton, N. Y.—Supt. of Water Wks. John Anderson is said to be in favor of the installation of water meters in this city.

Cape May, N. J.—The City Council has passed an ordinance granting to J. Pemberton Newbold, of Philadelphia, the franchise of laying mains and establishing a plant for the supplying of salt water to hotels and residences here.

Cranford, N. J.—The Union Water Co. is said to contemplate the construction of a stand pipe and pumping station at South Cranford on Rahway River, in order to supply increased demand for water in the towns along the Central between Plainfield and Elizabeth.

Salem, Va.—City Secy. John H. Palmer writes that a committee has been appointed to investigate as to the best means for a further water supply. W. B. Dillard, Chmn. of Com.

Marion, S. C.—Business men of this town are investigating a plan for the installation of a system of water works.

Fairmont, W. Va.—The City Council has decided to build a reservoir with a capacity sufficient to hold a 3 weeks' water supply for the city.

Lakewood, O.—Bids will be received by the Bd. of Trus. until Jan. 9 for laying the necessary water and sewer mains in several streets. John French, Hamlet, Clk.

New Bremen, O.—Local press reports state that bids will be received until Jan. 6 by the Village Trus. for $28,000 bonds, the proceeds to be used to construct water works and to furnish the citizens with water.

South St. Paul, Minn.—Press reports state that bids will be received until Jan. 5 for constructing a standpipe and laying water mains. Chas. W. Clark, City Recorder.

Chicago, Ill.—Contract Clk. Frank Murphy writes that the following bids were opened Dec. 11 for furnishing and delivering the following approximate quantities of cast iron water pipe: 400 pcs. of 4-in., 4,000 pcs. of 6-in., 3,000 pcs. of 8-in., and 500 pcs. of 12-in. internal diameter, I. B. Clow & Sons, Lake and Franklin Sts., per ton, $35.70; U. S. Cast Iron Pipe and Fdy. Co., Rookery Bldg., Chicago, per ton, $34.80 (awarded).

Menasha, Wis.—Mayor Geo. Banta writes that previous reports, to the effect that this city contemplates constructing water works, were incorrect.

Cedar Rapids, Ia.—According to press reports an ordinance has been passed providing for the purchase of the present water system or the construction of a new system. The question of issuing bonds will be submitted to the voters.

Shelbyville, Ind.—The Citizens' Water, Light, Power & Heat Co. will be organized, with a capital of $200,000. Harry Whitcomb and T. W. Fleming are said to be interested.

Two Harbors, Minn.—The village is reported to have voted bonds for improvements to the water and light plant.

Morgantown, W. Va.—See "Power Plants, Gas and Electricity."

Joliet, Ill.—Press reports state that the Water Comrs. have been directed to purchase an air compressor.

The contract for building a storage reservoir for the water works has been awarded to Wm. Tenney, for $9,974.

Philippi, W. Va.—Citizens, including Stewart Bowman, Jas. E. Hall and S. A. Moore, have incorporated the Philippi Water & Light Co. with $40,000 capital, to establish water works and lighting plant at Philippi.

Fostoria, O.—A report has been submitted to the City Council recommending the construction of a municipal water works plant.

Ottumwa, Ia.—An election will be held Jan. 6, at which the electors of the city will ratify or reject the contract entered into by the City Council with the U. S. Cast Iron Pipe & Fdy. Co., of Chicago, for furnishing, and with the Des Moines Bridge & Iron Wks. for laying pipe needed by the city for the new water works system For detail bids opened Dec. 1 see The Engineering Record of Dec. 6.

St. Paul, Minn.—Bids will be received until Jan. 15 by Geo. E. Pond, Ch. Q. M., St. Paul, for constructing a pumphouse and equipment, including pumps and boilers, a water tank and trestle, and the extension of mains at Ft. Snelling.

North Milwaukee, Wis.—Press reports state that water mains will be laid through the streets. The village will pay commercial rates for the water furnished by Milwaukee.

Kalamazoo, Mich.—The Grand Rapids & Indiana Ry. (S. B. Liggert, Asst. Secy., Pittsburg, Pa.,) will, it is stated, build a $12,000 pumping station at this place.

Cincinnati, O.—Ch. Engr. Bouscaren is reported to have completed designs and plans for the 3 steel coal sheds to be built for the water works, at a cost of about $100,000 each. Two of the sheds will be 132x72 ft., and the other 228x72 ft. in size.

El Reno, Okla. Ter.—Press reports state that about Jan. 1 the El Reno Water Co. will let contracts for 2 pumps of 1,000,000 gal. capacity, boiler, etc.

Owensboro, Ky.—The City Council has passed a resolution appointing Mayor Yewell and Councilmen Slaughter, Steitler and Delker a special Water & Light Com., and instructing them to employ a competent engineer to make plans and specifications for a new water works. This committee was also instructed to enter into negotiations with the Owensboro Water Works Co. with a view to buying the present water works system, provided it can be bought for an amount not to exceed $90,000. Water works bonds to the amount of $200,000 are said to have been offered for sale by City Clk. O'Bryan.

Woodville, Miss.—An election will be held to vote on the issue of $30,000 city bonds for the construction of water works and electric lights.

Terry, Okla. Ter.—Bonds to the amount of $50,000 are reported to have been voted for water works. F. F. Busch Clk.

Beaumont, Tex.—The Beaumont Irrigation Co. has filed an amendment to its charter increasing its capital stock from $150,000 to $300,000.

Memphis, Tenn.—The stockholders of the Artesian Water Co. on Dec. 8 officially accepted the proposition of the city of Memphis to buy its plant. The city is said to be paying for the plant $2,346,000 and assuming the outstanding indebtedness of the Co., estimated to be about $60,000.

Ardmore, Ind. Ter.—Bids are wanted Jan. 6 for furnishing material and doing the following work in connection with the construction of water works: Pumping machinery, fire hydrants, gate valves and valve boxes, steel water tower, 24x125 ft., laying about 12 miles of mains, and constructing a pumping station. Chester B. Davis, Engr., San Antonio, Tex. Geo. H. Bruce, City Clk.

Granger, Tex.—Press reports state that the Granger Water Co. proposes to purchase gasoline engine, pumps, etc. W. H. Kelso, Mgr.

Searcy, Ark.—It is stated that the time for receiving bids for constructing a water works and an electric light plant has been extended from Dec. 26 to Dec. 30. Owen Ford, Engr., Security Bldg., St. Louis, Mo.; Emmet Snipes, Secy. of Com.

Kansas City, Mo.—Bids will be received by the Bd. of Pub. Wks. until Dec. 29 for furnishing and erecting complete, under boilers, at Turkey Creek Pumping Station, 2 mechanical stokers, having sufficient grate area to furnish 300 H.-P., burning bituminous slack coal. Baxter Brown, Secy.

Centerville, Miss.—Bids will be received by the Bd. of Mayor and Aldermen until Jan. 7 for constructing a system of water works, according to plans and specifications prepared by C. H. Jenks, Engr., Fayette. Address, Ackland H. Jones, Centerville.

Flagstaff, Ariz.—Town Clk. L. W. Quinlan writes that on Dec. 8 it was voted to issue $10,500 supplementary water works bonds.

Sioux Falls, S. D.—The City Aud. has been directed to ask for bids designed for the purpose of commencing work on a municipal water works plant.

Alcester, S. D.—A site has been purchased by the trustees for a water works plant. A deep well will be sunk.

Denver, Colo.—Plans for the building of a 3-mile tunnel through the mountains for the purpose of irrigating 100,000 acres of arid land, near Denver, have been about completed by the Agricultural Ditch Co. and the Church Ditch Co. It is reported that there is more than $1,000,000 back of the scheme. Henry Lee, Secy., Agricultural Ditch Co.

Perry, Utah.—Articles incorporating the Three-Mile Creek Irrigation & Water Co., with Perry as the principal place of business, have been filed. Capital stock, $50,000. The directors are: Barnard White, Jas. Nielson, Richard Thorn, Alma Wright, and others.

Salt Lake City, Utah.—A. B. Lewis is said to be interested in the development of a water power in Beaver County; it is stated that the project provides for the irrigation of 4,000 acres of land and the development of 800 H. P. for mining enterprises in Beaver Co.

Corona, Cal.—At the recent annual meeting of the stockholders of the Temescal Water Co., the articles of incorporation were amended for the purpose of empowering the Co. to carry through the proposed purchase of water-bearing lands, developed water and pumping plant in the Perris Valley.

Montrose, Colo.—At a recent citizens' meeting a resolution was passed recommending to the Town Bd. the Cimarron Canal as the only practical and economical source of pure water supply for this town.

Gunnison, Colo.—Articles of incorporation have been filed by the Gunnison & Ohio Creek Canal Co. Incorporators: John A. Allen, A. E. Hyzer and A. F. Cunningham.

Ukiah, Cal.—Press reports state that local citizens propose to place a dam at the lower end of Walker Valley for the storing and conserving of water for irrigation and power purposes.

North Yakima, Wash.—Articles of incorporation of the Moses Lake Irrigation Co. have been filed here. The capitalization is $5,000. The incorporators are C. G. Wands, David Longmire, A. E. Treat and S. S. Wheeler.

Seattle, Wash.—The estimated cost of new cast-iron water mains to cover the West Queen Anne Dist,. has been placed at $53,000, and the estimated cost of a wooden water main for Stowe St. and other streets on Bigelow Hill, $10,500.

Pomona, Cal.—It is stated that bids are wanted Jan. 3 for furnishing the Del Monte Irrigation Co. 1 steel tank of 10,000 gal. capacity. W. A. Lewis, Secy.

Wessington Springs, S. D.—The sum of $2,500 has been voted for sinking an artesian well.

Alberta, N. W. Ter.—Local papers state that the Canadian Pacific Ry. (Wm. Whyte, Mgr. of the Co.'s western lines, Winnipeg, Man.) proposes to irrigate two and a half million acres of semi-arid lands lying in the district between Calgary and Medicine Hat, the water to be obtained from Bow River.

Ottawa, Ont.—In his annual report to the Water Wks. Com., City Engr. Ker recommends the construction of water mains in several streets, estimated to cost in all $36,485.

Toronto, Ont.—The by-law to provide $175,000 for a new 15,000,000 gal. pumping engine has received its first and second readings in the City Council, and will now be submitted to the ratepayers, and if approved by them will be given its third reading by next year's Council.

Montreal, Que.—Fire Chief Benoit favors the city putting in large water mains. Probable cost, $30,000 to $50,000.

SEWERAGE AND SEWAGE DISPOSAL.

Providence, R. I.—Bids will be received until Dec. 26 by Robt. E. Smith, Comr. of Pub. Wks., for 14,400 ft. of 12 and 15-in. straight pipes and 22,000 ft. of 6 and 8-in. (2-ft. lengths) straight pipes, 150 ft. 12x8-in., 3,000 ft. 12x6-in., 30 ft. 8x8-in., 300 ft. 8x6-in. branch pipes, the last two sizes to be of 2-ft. lengths, 100 pcs. of 8-in. 1/8 bends, 50 pcs. of 8-in. 1/16 bends, 100 pcs. 6-in. 1/8 bends, etc.

New Britain, Conn.—Bids are wanted Jan. 6 for the construction of Section 2 of the New Britain sewerage system consisting of a tunnel 1,048 ft. long and approaches 680 ft., including manholes, etc., as advertised in The Engineering Record.

Woonsocket, R. I.—City Engr. F. H. Mills writes that the City Government has appropriated $5,000 for an additional filter bed.

Bridgeport, Conn.—The Sewer Com. will ask for an appropriation of $12,000 for the construction of Noble Ave. sewer. E. T. Buckingham, City Clk.

Boston, Mass.—The following bids were opened Dec. 15 by the Metropolitan Water & Sewerage Bd., for Section 48 High-Level sewer, Quincy; bidders' addresses Boston, unless otherwise stated:

Bidders and addresses.	In trench and embankment. Earth excav. & refill., 135x150-in. sewer, 5,880 ft.	Br. masonry, Amer., 2,500 cu. yds.	Br. masonry, Port., 3,000 cu. yds.	Con. masonry, Port., 15,000 cu. yds.	Boulder con. mas., Port., in trench, 9,000 cu. yds.	Spruce piles, 100,000 lin. ft.	Spruce lumber in trench, 10 M ft.	Totals.
Gow & Foss	$13.50	$13.50	$15.50	$6.75	$5.50	$0.25	$40.00	$335,780

Dennis F. O'Connell, Dorchester.	5.46	12.00	13.25	5.40	3.75	0.145	40.00	231,505

Brooklyn, N. Y.—Bids will be received until Dec. 31 by J. Edw. Swanstrom, Boro. Pres., for furnishing material and constructing a sewer in a portion of New York Ave., and outlet sewers in portions of New York, Newkirk and Nostrand Aves., also for furnishing material and constructing small sewers in portions of several streets.

Philadelphia, Pa.—Bids will be received until Dec. 24 by the Dept. of Pub. Wks., Bureau of Surveys, for supplies for Bureau of Surveys for 1903 and main sewer. Wm. C. Haddock, Dir.

New York, N. Y.—Bids are wanted Dec. 23 for furnishing material and building an extension to outlet sewer at the foot of W. 72d St., and for furnishing material and building sewers in Broadway, between 28th and 29th Sts. Jacob A. Cantor, Boro. Pres.

Lebanon, Pa.—A correspondent writes that the question of city sewerage is being agitated.

East Syracuse, N. Y.—At a recent meeting of the Village Bd. the Sewer Comrs. presented a complete report from Geo. W. Rafter, of Rochester, upon the proposed sewer system for this village. The report favored the original route decided upon by Village Engrs. Allen & Farrington, of Syracuse, some time ago.

York, Pa.—Mayor Gibson has signed the ordinance providing for a special election to vote on the question of increasing the city's indebtedness $400,000 for the building of a sanitary sewerage system.

Richmond Hill, L. I., N. Y.—Engineer Johnson, of the Sewer Dept. of the Boro. of Queens, is said to be preparing plans for a proposed sewerage system for Richmond Hill to connect with the Jamaica disposal plant.

Reading, Pa.—The Bd. of Pub. Wks. has been asked for an appropriation of $12,000 for a settling basin to be added to the filter beds at the sewage disposal plant.

St. Petersburg, Fla.—City Engr. J. P. Titcomb writes that the City Council is considering the following bid, opened Dec. 10 for the construction of a sewerage system; the city to furnish all pipe, castings for manholes and flush tanks, which materials are now on the site of proposed work: D. M. Baker, Jacksonville, Fla., $6,689; Coates Plumbing Co., Tampa, Fla., $6,066; and W. C. Porter, of Laurel, Miss., $5,672. The detail bid of W. C. Porter was as follows: Pipe—6,025 ft. 6-in. at 25 cts., 4,420 ft. 8-in. at 30 cts., 1,970 ft. 10-in. at 35 cts., 860 ft. 12-in. at 50 cts., 325 ft. 15-in. at 60 cts., 100 ft. 16-in. C. I. pipe, $2; 25 manholes at $40, 5 flush tanks at $65. The trench is to average 6.7 ft. to be excavated in sand.

Cleveland, O.—Bids will be received by the Clk. of the Bd. of Control until Jan. 8 for constructing an intercepting sewer in a portion of Lake St. consisting of a tunnel in Marquette St., from Lake St. northerly a distance of about 675 ft. Chas. P. Salen, Dir. Dept. of Pub. Wks.

Lakewood, O.—See "Water."

South Bend, Ind.—City Engr. Alonzo J. Hammond writes that the Bd. of Pub. Wks. has directed him to prepare plans and estimates for a trunk sewer in the western portion of the city: also for a trunk sewer on the east side, both to be built in 1903.

Madison, Wis.—City Clk. O. S. Norsman writes that the following bids were opened Dec. 12 for furnishing material and constructing 2½ miles of sanitary sewers ranging in size from 6 in. to 12 in.: John Delaney, Madison, Wis., $14,800; Harding, Nelson & Johnson, Racine, Wis., $13,975. Both bids were rejected. The City Engr., John F. Icke, estimates the cost at $12,300, and the city will undertake to do the work.

Des Moines, Ia.—The City Council has passed a resolution of necessity for a sewer on Park Lane from Grand to Woodland Ave.

Indianapolis, Ind.—Petitions are being circulated for a complete system of sewerage for West Indianapolis.

The Bd. of Wks. on Dec. 15 adopted resolutions for Roosevelt Ave. sewer, estimated cost $33,300; also Hillside and Bloyd Aves. sewer, estimated cost $18,900.

Vincennes, Ind.—The contract for constructing St. Clair St. sewer is reported to have been awarded to D. W. Norton & Co., of Terre Haute, for $14,703.

Ottawa, Ill.—City Engr. Chas. F. Wilson writes that petitions are now being circulated for the construction of a sewerage system in West Ottawa.

Cincinnati, O.—The contract for constructing sewers on Price Hill, in 8th Ave., W. 8th, Wells and other streets, is reported to have been awarded to McCarthy Bros. for $16,016.

Chicago, Ill.—Bids will be received by the Bd. of Local Improv. until Dec. 26 for constructing a sewer in South 43d Court, and for completing the contract for a system of sewers in North 40th Ave., Milton Place, and Warwick Place. John A. May, Secy.

Sault Ste. Marie, Mich.—An ordinance is said to be before the Council to authorize the issue of $35,000 bonds for establishing a sewer system.

Clay Center, Kan.—Local press reports state that bids will be received by the Mayor until Jan. 16 for constructing a sewer system.

Bessemer, Ala.—City Engr. W. J. Parkes writes that the work of constructing Second Ave. Dist. storm sewers (bids for which were to have been opened Nov. 18) has been postponed until the spring. Estimated cost, $7,500.

St. Louis, Mo.—The lowest bid for the reconstruction of a part of Mill Creek sewer is reported to have been from Heman Bros. at $16.90 per ft.; appropriation, $15,000.

East Lake, Ala.—The City Council is said to be taking steps looking to the installation of a sanitary sewerage system. Probable cost, $25,000.

Knoxville, Tenn.—Local papers quote City Engr. T. J. Moreland as having stated that sewer extension, which should be made immediately, would cost about $75,000.

Kansas City, Mo.—City Engr. Robt. W. Waddell writes that on Dec. 16 the following bids were opened for the construction of sewers in Sewer Dist. No. 211, the work to include 30,000 ft. of 8 in. to 4 ft., pipe and brick sewers, with 102 manholes, 62 catch basins and 7 flush tanks: Michael Walsh (awarded), $71,170.70; W. J. & Wm. Boyd Const. Co., $72,366.24; Cotter-McDonald P. & H. Co., $77,032.73; Luther Davidson, $73,141.66. Bidders all of Kansas City.

North Yakima, Wash.—The East Sunnyside Drainage Canal Co. has been organized for the purpose of getting rid of the surplus water on the land to the east of Sunnyside, which results from too much irrigation. The officers elected for the ensuing year are: Pres., J. T. Kunz; vice-pres., I. R. Noble; secy., M. D. Clarke; treas., J. A. Rush.

Long Beach, Cal.—The City Trus. have called an election for Dec. 30 to decide the question of issuing $35,000 bonds for sewer construction. The main sewer to be 18 in. and run through the city east and west on Second St., with a separate tank and outfall to the ocean.

Ballard, Wash.—The proposition to issue bonds to the amount of $20,000 for sewers, is reported to have carried at the recent election.

Colorado Springs, Colo.—Local press reports state that work will be started without delay on the construction of the proposed Cripple Creek drainage tunnel; said tunnel to start on Cripple Creek at the mouth of Arequa gulch and to be extended for a distance of 5,000 ft. eastward. Estimated cost about $100,000. F. F. Costello, Sherwood Aldrich and Sam. Bernard are on the Com. from Colorado Springs.

Ft. Assinniboine, Mont.—See "Government Work."

San Francisco, Cal.—The City Engineer has just completed plans and specifications for a sewer to be constructed in Harrison St. at an estimated cost of $4,200. The Bd. of Pub. Wks. has determined to construct other sewers on streets and avenues adjacent to the above, cost of which will be approximately $40,000; and plans for same have just been ordered.

Toronto, Ont.—Bids are wanted Dec. 23 for constructing tile sewers in portions of several streets. O. A. Howland (Mayor), Chmn. Bd. of Control.

Toronto, Ont.—The City Council has decided to adopt the recommendation of the City Engr. that a system of sewage disposal east of Woodbine Ave. be constructed as a local improvement at an estimated cost of $45,000.

BRIDGES.

Camden, N. J.—Local press reports state that bids will probably be received by the Bridge Com. for constructing a steel draw bridge, 125 ft. span, stone abutments and pier, across Cooper Creek at Baird Ave. Appropriation, $20,000.

Elizabeth, N. J.—It is stated that the Union Co. Bd of Freeholders has decided to construct a Melan bridge at Prince St.

Baltimore, Md.—Press reports state that the B. & O. and the Pennsylvania Railroads contemplate abandoning their bridges across Susquehanna River, and are considering the construction of one, to be used in common, about half way between the two.

York, Pa.—Local press reports state that $44,000 has been appropriated for the building of the Richland Ave. bridge.

Depew, N. Y.—Press reports state that the officials of the N. Y. C. & H. R. R. R. have awarded a contract to the Boston Bridge Co. for the building of 10 standard signal bridges on the Western Division of the road.

Perry, N. Y.—The Bd. of Superv. has passed a resolution authorizing this town to borrow $7,000, and to issue bonds therefor, for the building of an iron bridge across Silver Lake.

Franklin, Pa.—E. K. Smiley, Clk. of the Co. Comrs., writes that the contract for constructing a steel bridge (substructure and superstructure) over Allegheny River at Scrubgrass, has been awarded to Penn Bridge Co., Beaver Falls, Pa., for $79,900.

Allegheny, Pa.—G. C. Langenheim, Supt. Bureau Eng. & Surveys, writes that the following bids were opened Dec. 11 for work on the bridge to cross Woods Run Valley at Shady Ave.:

Masonry Piers and Abutments—Cronin & O'Herron, Pittsburg, $19,850; Grady C. Coda & Co., Pittsburg, $18,065; Barton & Miller, Allegheny, $16,779; Keeling & Ridge Co., Pittsburg, $15,725.

Superstructure—King Bridge Co., Cleveland, O., $90,500; Penn Bridge Co., Beaver Falls, Pa., $90,000; W. Va. Bridge & Const. Co., Wheeling, W. Va., $88,400; Ft. Pitt Bridge Wks., Pittsburg, $88,150; American Bridge Co., Pittsburg, $87,475.

Paving Roadway and Sidewalks—Sicilian Asp. Paving Co., New York, N. Y., $9,275; Penna. Asp. Paving. Co., Pittsburg, $7,525; Atlas Const. Co., Pittsburg, $7,175; Wadsworth Stone & Paving Co., Pittsburg, $6,143. Contract has not yet been awarded.

New York, N. Y.—J. C. Rodgers has secured the contract for constructing the tower foundation in the Boro. of Manhattan of the Manhattan Bridge (No. 3) over the East River, between the Boroughs of Manhattan and Brooklyn, for $482,726.

Washington, D. C.—A bill has passed the House authorizing the Great Falls & Old Dominion R. R. Co. to construct a single electric railway track across Aqueduct bridge. A deposit of $25,000 is to be made by the Railroad Co., with which the District Comrs. will reconstruct the superstructure of said bridge to make it suitable for the track.

Scranton, Pa.—Bids will be received until Jan. 12 by John E. Roche, Dir. Dept. of Pub. Wks., for constructing a viaduct along Lackawanna Ave. from 7th Ave. to 9th Ave., across and over the tracks of the Delaware, Lackawanna & Western R. R.

Danville, Ill.—W. S. Dawley, Ch. Engr. of the Chicago & Eastern Illinois R. R., and W. S. Danes, Supt. of Bridges & Bldgs. of the Wabash R. R., are reported to have decided to remove the wooden bridge at Seminary St. and to replace it with an iron structure.

Uhrichsville, O.—Press reports state that the officials of the Pittsburg, Cincinnati, Chicago & St. Louis Ry. contemplate building a bridge in this city at what is known as "52 cut."

Lockland, O.—The citizens of Lockland and Reading are anticipating the building of a bridge across the canal at Benson St.

Moline, Ill.—The building of a high bridge from Moline to Gilbertown is under consideration.

Youngstown, O.—Preliminary steps are being taken for the issuance of bonds for the building of the Mill Creek bridge.

Hazleton, Ind.—The citizens of Hazleton are about to petition the Co. Comrs. of Knox and Gibson Counties to bond for the construction of a bridge in this town.

Freeport, Ill.—The construction of a bridge across Pecatonica River, near Scioto Mills, is being considered.

Carlyle, Ill.—Press reports state that plans and bids are wanted by Chas. Wilton, Town Clk., for 2 iron bridges, 200 ft. long, to be built next spring.

Huntington, Ind.—It is stated that bids will be received Dec. 30 for constructing a truss bridge, 20 ft. wide, on stone or concrete foundation, near Huntington. Herman Taylor, Co. Surv.

Enon, O.—The Co. Comrs. have decided to erect an iron bridge across Mad River, near Enon, at a cost of between $5,000 and $8,000.

San Antonio, Tex.—The matter of building a viaduct at Nueva St. is under consideration.

Castroville, Tex.—The Commissioners' Court at Hondo has selected the plan of S. A. Oliver, of Houston, for the bridge to be built across Medina River, this city, consisting of 1 252 ft. steel span and 2 100 ft. spans, on 2 stone abutments and 2 stone piers, estimated to cost $12,500.

Mammouth Springs, Ark.—The Kansas City Bridge Co., Kansas City, Mo., is reported to have secured the contract to construct a 350 ft. steel bridge in this city for $6,476.

Spokane, Wash.—See "Electric Railways."

Sacramento, Cal.—The Bd. of Superv. has accepted plans and specifications prepared by Co. Surv. J. C. Boyd for a bridge to be built at Millers Ferry, across San Joaquin River, between Sacramento and San Joaquin Counties. Estimated cost, $20,000.

Bowbell, N. D.—Local press reports state that the Co. Auditor will ask bids for constructing bridges across Mouse River, as soon as plans and specifications have been received.

Colorado Springs, Colo.—The officials of the Santa Fe R. R., according to local press reports, have made an offer to the city to construct a steel bridge, 60 ft. wide, at Costilla St.

Sioux Falls, S. D.—The Co. Comrs. have ordered the building of a 150 ft. span steel bridge in Split Rock Township, a 130 ft. span steel bridge in Brandon Township, and a 70 ft. steel bridge across Beaver Creek, in Valley Springs.

Tacoma, Wash.—It is stated that bids will be received Jan. 12 for constructing a 350 ft. plate girder or truss bridge, on concrete foundation, across a gulch in this city. Estimated cost, $4,600. Norton L. Taylor, City Engr.

San Diego, Cal.—The Chamber of Commerce is reported to have recommended the building of a steel bridge across San Diego River.

MacLeod, N. W. Ter.—A. L. Sifton, Comr. of Pub. Wks., N. W. Ter., is reported to be desirous of securing bids for supplying material for building a bridge at MacLeod, to cost $20,000, and also one at Lethbridge, to cost $40,000.

Portland, Ore.—The building of a suspension bridge across Willamette River is under consideration.

Thornhill, Ont.—The Canada Foundry Co. is reported to have secured the contract for constructing a bridge across the east branch of Don River, this city, for $6,602.

PAVING AND ROADMAKING.

Hartford, Conn.—Geo. Nevers, Clk. Bd. of Street Comrs., writes that the contract for furnishing and laying the concrete base and sheet asphalt wearing surface of about 5,605 sq. yds. on Pearl St., has been awarded to the Southern New England Paving Co., Hartford, at $2.70 with 10-year guarantee, $6.60 per cu. yd. for concrete in excess of 4 ins., total about $16,000.

Pittsburg, Pa.—Representative citizens and business men have formed an organization to be known as the Road Drivers' Asso. of Pittsburg; O. H. Allerton, Pres.; Wm. McFarland, Secy., and F. B. Haas, Treas. Plans submitted by Engr. Brown for Beechwood boulevard have been adopted; they provide for a course 5,000 ft. long and 80 ft. wide, to consist of 8 ins. of broken stone, 3 ins. of cinder and 6 ins. of sand. Probable cost, $70,000 to $90,000.

Corinth, N. Y.—The Saratoga Co. Bd. of Superv., Ballston Spa, has voted authorizing a survey for 4 additional miles of road in Corinth.

Brooklyn, N. Y.—Pub. Wks. Comr. Redfield is said to be preparing to purchase a road stone-breaking machine and other implements necessary for the repair of roads in suburban districts.

Baltimore, Md.—The contract for paving Northwest St. has been awarded to Daniel Sullivan; for detail bid see The Engineering Record of Dec. 13.

Philadelphia, Pa.—The Bd. of Surveyors on Dec. 15 gave their tentative approval to the ordinance introduced at the last meeting of Common Council to place on the city plan an avenue 300 ft. wide, extending from Broad and Cayuga Sts. northeasterly for 8 miles; estimated cost, $2,500,000.

Buffalo, N. Y.—Bids will be received by the Dept. of Pub. Wks. until Dec. 27 for repaving portions of Fillmore and Lafayette Aves. Francis G. Ward, Comr. Pub. Wks.

New York, N. Y.—Bids are wanted Dec. 23 for regulating and repaving with asphalt on present pavement relaid as foundation a portion of 23d St. Estimated quantities: 14,220 sq. yds. of asphalt pavement, including binder course; 11,560 sq. yds. of old pavement, to be relaid as foundation or in approaches, etc.; 360 cu. yds. of concrete, 6,200 lin. ft. of new bluestone curb, furnished and set, etc., for regulating and repaving with asphalt on present pavement relaid as foundation a portion of Houston and Varick Sts., requiring 2,320 sq. yds. of asphalt, including binder course; for regulating and repaving with asphalt block on a concrete foundation Lexington Ave., from 95th to 96th Sts. Jacob A. Cantor, Boro. Pres.

Schenectady, N. Y.—City Engr. C. W. Truman writes that contracts for paving (bids opened Dec. 9) have been awarded to the Schenectady Contracting Co., of Schenectady, as follows—*a*, asphalt paving per sq. yd.; *b*, curbing; *c*, total: Lincoln Ave.: *a*, $2.10; *b*, 85 cts.; *c*, $12,500. Seward Place, *a*, $2.20; *b*, 85 cts.; *c*, $11,855. South Ave., *a*, $2.20; *b*, 85 cts.; *c*, $3,655.

New York, N. Y.—Plans have been completed for the extension of Riverside Drive, from the Manhattan viaduct at 135th St. to the Boulevard Lafayette at 156th St.; these plans provide for a carriage road 60 ft. wide, a bridle path 20 ft. wide, 2 broad walks and grass plats between the road and walks 5 ft. wide. Total estimated cost, including viaducts, bridges, etc., $2,700,000.

Waynesburg, Pa.—Boro. Engr. Geo. D. Jenkins writes that on Jan. 6 this Boro. will vote on the issue of $40,000 bonds for further street improvements.

Waterloo, N. Y.—The Seneca Co. Bd. of Superv. on Dec. 12 adopted a resolution recommending the construction of 35 miles of State road in the towns of Seneca Falls, Fayette, Varick, Romulus, Ovid and Lodi.

Philadelphia, Pa.—Bids were opened Dec. 16 by Dir. Haddock, of the Dept. of Pub. Wks., for work, material and supplies for 1903. The principal items were estimates for work to be done on the highways of the city. Bids received for the maintenance of unpaved and macadamized public highways, small bridges, drains and steps for next year are reported to have been as follows for the entire city: Geo. A. Vare, $114,000; D. J. McNichol, $132,000; J. R. Stanley, $123,000; David MacMahon, $129,000. Bids for general repairs to footways and repaving: Vulcanite Paving Co., $2.49 with asphalt where concrete binder has to be removed, and $2.34 where binder is not disturbed. Geo. T. Murray is stated to have bid $2.50 per sq. yd. for granolithic pavement. Pennsylvania Asphalt Co., to pave with asphalt where binder has to be renewed, $2.60 a sq. yd.

New York, N. Y.—Bids were opened Dec. 12 by McDougall Hawkes, Comr. Docks, for paving with asphalt the new-made land between 18th and 21st Sts., East River, and with granite between piers old 20 and new 16, East River, as follows, the bid of the Barber Co. being admitted under protest because of claim that sufficient security was not given before bidding was closed: Class I (per sq. yd.), Uvalde Asph. Pavg. Co., $3.05; Continental Asph. Pavg. Co., $2.90; Barber Asph. Pavg. Co., $2.85. Class II, 18,059 sq. yds., Sicilian Asph. Pavg. Co., $3.47; Uvalde, $2.75; Continental, $2.39; Barber, $2.20.

Allegheny, Pa.—Bids will be received until Dec. 23 for regrading, repaving, curbing and paving on portions of numerous streets. D. K. Fulton, Dir. Dept. Pub. Wks.

Savannah, Ga.—The City Council has before it ordinances for paving with brick Henry, East Broad and Habersham Sts., in all about 35,000 sq. yds.; work to be started next month.

Portsmouth, Va.—The City Council has granted the Finance Com. permission to ask for bids for $50,000 paving and grading bonds, the passage of which is now pending in the Legislature.

Cleveland, O.—Bids are wanted Dec. 23 for grading, draining, curbing and paving with brick on portions of numerous streets; also until Jan. 6 for similar work on portions of several other streets. Chas. P. Salen, Dir. Pub. Wks.

Marshalltown, Ia.—City Engr. Wm. Bremner writes that the City Council has taken preliminary steps toward the paving of nearly ½ mile of streets with brick; also about 4,500 ft. of asphalt paving.

Belleville, Ill.—City Engr. Louis Grauer writes that this city is preparing to pave 5 blocks on South Race St. with brick, also to pave 6 blocks on 1st St.; the work to be started in the spring as soon as the weather will permit.

Akron, O.—Bids will be received by the Bd. of City Comrs. until Dec. 27 for improving a portion of Rose Ave., by grading, curbing, and guttering with concrete, paving with brick, laying cement sidewalks, and constructing a sanitary sewer. Chas. H. Isbell, Clk.

Burlington, Ia.—City Engr. Emmet Steece writes that bids will be asked about Feb. 1 for 20,000 sq. yds. of brick paving in this city.

Bay City, Mich.—The County Road Comrs. are said to contemplate the purchase of a road roller and a stone crusher to use in the construction of county roads.

Janesville, Wis.—City Engr. C. V. Kerch writes that the City Council has ordered plans prepared for the improvement of Milwaukee Ave.

Ludington, Mich.—This city has voted to issue $20,000 bonds for street improvements.

Crookston, Minn.—The Common Council has approved the contract of the city with the Barber Asphalt Paving Co. for the paving of the principal business streets. The contract is said to call for an expenditure of about $60,000.

Faribault, Minn.—The Council is reported to have decided to pave the streets in the business section of the city next season.

Bloomfield, Ind.—Amos Musselman and Chas. O. Morgan, of Newberry, Ind., are reported to have received the contract for constructing Stockton Township gravel roads; total length, 15 miles. Estimated cost, $48,646.

Traverse City, Mich.—The Council Com. on Streets and Walks has ordered plans, specifications and estimates prepared for paving 6th St. with brick or asphalt. Blomshield & McCloy, of Bay City, are the engineers.

Normal, Ill.—J. G. Melluish, of Bloomington, Ill., writes that he is to report on asphalt pavement 30 ft. wide, with combined cement 6-in. curb and 18-in. gutter, to be laid on Fell Ave., Normal. Length of improvement, 6,500 ft. Estimated cost, exclusive of street car right of way, $40,221. The ordinance provides for 6-in. water mains and 24, 12 and 10-in. pipe sewers to be laid on Fell Ave.

St. Louis, Mo.—Bids will be received by the Bd. of Pub. Improv. until Dec. 30 for grading, curbing, improving, and paving with bituminous macadam on portions of several streets. Hiram Phillips, Pres.

Birmingham, Ala.—City Engr. Julian Kendrick writes that an ordinance has been introduced for the construction of 18,000 sq. yds. of bituminous macadam pavement.

Brookfield, Mo.—According to press reports steps are being taken toward paving Main St.

Louisville, Ky.—The lowest bid received for paving a portion of Peterson Ave. and the square at the intersection of 28th St. and Garland Ave. is reported to have been from Geo. W. Gosnell at $1.38 per sq. yd. for brick, total about $4,900.

Wichita, Kan.—The contract for repairing approximately 70,000 sq. yds. of asphalt pavement has been awarded at $1.10 per sq. yd.

Guthrie, Okla. Ter.—The contract for brick paving (bids opened Dec. 11) is reported to have been awarded to E. N. Ford, of Kansas City, Mo., at his bid of $1.88 per sq. yd.; total, $76,942.

St. Joseph, Mo.—Petitions have been issued for brick and macadam paving on several streets.

Ft. Smith, Ark.—A correspondent writes that this city is in the market for 100,000 paving brick, and more will be wanted soon.

Ogden, Utah.—City Engr. A. F. Parker writes that the Council has directed him to prepare plans and specifications and call for bids, for 2 blocks of paving on Washington Ave.

Denver, Colo.—The contract for sidewalk construction in Dist. No. 8 is reported to have been awarded to J. Fred Roberts at 82 cts. for new 5-ft., 2½-in. stone; total, $18,706.

San Francisco, Cal.—The Bd. of Wks. has awarded the contract for paving the roadway of Mission St. with bitumen, to the Union Paving Co., for $9,681.

Salt Lake City, Utah.—The Council has adopted a resolution instructing the City Engr. to prepare an estimate of the cost of paving Brigham St.

San Diego, Cal.—The directors of the Chamber of Commerce are said to recommend the purchase of a steam roller and oil plant for improving the streets.

Oakland, Cal.—The City Engineer has been requested to make an estimate of the cost of improving a portion of 5th St. Probable cost, $30,000.

POWER PLANTS, GAS AND ELECTRICITY.

Holyoke, Mass.—Municipal lighting bonds amounting to $720,000 have been sold. The lighting plants of the Holyoke Water Power Co. were transferred to the city Dec. 15. W. H. Snow will be Acting Mgr.

Weymouth, Mass.—The Weymouth Light & Power Co. is stated to have petitioned the Gas & Electric Light Comrs. for authority to increase its capital from $50,000 to $100,000, and to increase its bonded indebtedness from $50,000 to $85,000. The company proposes installing a new engine and machinery and purchase the property of the Weymouth Water Co.

Sellersville, Pa.—An ordinance has passed first reading granting to Morris A. Clymer, of Sellersville, a franchise for an electric light plant.

Richfield Springs, N. Y.—It is stated that the Otsego Light & Power Co., recently incorporated at Albany to furnish light and power to all of the villages on the route of the O., C. & R. S. R. R. in Herkimer and Otsego Counties, has petitioned the Bd. of Trus. for a franchise in this village.

Rochester, N. Y.—Jas. Craig Havemeyer, of New York, is stated to have purchased the plant of the Central Light & Power Co. The plant will probably be improved.

Brook Haven, L. I., N. Y.—The Town Bd. is stated to have granted a franchise to the Brook Haven Gas Co. Thos. G. Carlin, Pres., Brooklyn.

Dunkirk, N. Y.—The Bd. of Water Comrs. on Dec. 11 authorized the Electric Light Com., consisting of Messrs. Cummings, Weller and Carney, to ask for bids for the purchase of a new 350-Kw. alternating generator and engine and boiler to operate same.

Cooperstown, N. Y.—Bids will be received by the Bd. of Village Trus. until Dec. 26 for lighting the streets and Village Hall. The Bd. is to contract for 1 year, with the privilege of extending the time to 5 years. Address Village President.

Geneva, N. Y.—A press report states that the General Electric Co. is planning to install a plant at East Geneva, to furnish electricity for lighting and power purposes in Geneva, Waterloo, Seneca and Auburn.

Oneonta, N. Y.—The Otsego Light, Heat & Power Co., of Oneonta, has been incorporated, with a capital of $100,000, to operate in Oneonta, Laurens, Hartwick, Exeter, Otsego, Milford, Warren, German Flats, Richfield, Cooperstown, Richfield Springs, Mohawk and Herkimer. Directors: Edw. C. White and Herbert F. Jennings, of Mt. Vernon, and Chas. V. D. Peck, of Brooklyn.

Denton, Md.—The Citizens' Light & Fuel Co., of Caroline County, has been incorporated, with a capital of $20,000, by Wm. H. Deweese, Albert G. Towers, J. Kemp Stevens, and others.

Savannah, Ga.—The Savannah Electric Co. is stated to have secured the contract for lighting the city for a period of 5 years.

Manchester, O.—Bids are wanted Dec. 27 for $7,000 electric light bonds. S. N. Greenler, Clk.

St. Paul, Minn.—The Cleveland Vapor Light Co. is stated to have secured the contract for incandescent gasoline street lights for 1903, at $23.96 per lamp per year.

Winona, Minn.—City Engr. G. P. Coleman writes that the City Council has accepted plans and specifications for erecting a municipal electric light plant. Bids will be opened on Jan. 5, as advertised in The Engineering Record. Bids will also be opened at the same time for $40,000 bonds.

Ft. Wayne, Ind.—S. M. Foster, W. J. Vesey, and others are stated to have petitioned the Bd. of Pub. Wks. for a franchise for a heating and lighting plant for the purpose of supplying buildings with steam or hot water heat from a central plant.

Vincennes, Ind.—See "Electric Railways."

Fostoria, O.—It is stated that the Fostoria Home Htg. & Lighting Co. will soon commence the construction of an electric light plant. J. S. and J. W. Barber, of Columbus, are reported interested.

Morgantown, W. Va.—The plant of the Union Gas & Water Co., which controls all the gas and water business of the town, is stated to have been sold to S. B. Elkins and G. C. Sturgiss. The consideration was about $500,000 and about $200,000 will be expended at once on improvements.

Red Jacket, Mich.—John Burder is stated to have secured a 30-year heating and lighting franchise.

Effingham, Ill.—Press reports state that bids will be received Jan. 1 for constructing a modern electric light plant. J. B. Walker, Pres.

Two Harbors, Minn.—See "Water."

Milwaukee, Wis.—The Council has passed an ordinance providing for the issue of $150,000 bonds for a municipal lighting plant.

The Northwestern Heat, Light & Power Co., of Milwaukee, has been incorporated, with a capital of $25,000, to supply light, heat and power in this county. Incorporators: Fred, Max and L. Nohl, all of Milwaukee.

Phillipi, W. Va.—See "Water."

Excelsior Springs, Mo.—Henry J. Arnold is stated to have petitioned the Council for a franchise for an electric light plant.

Springfield, Mo.—The Electric Light Co. is reported reorganized. The new company is composed of F. W. Little of Peoria, Ill., and Mason, Lewis & Co., of Chicago. It is stated that about $50,000 will be expended in improvements.

Watauga, Tenn.—The Watauga Electric Co. is reported incorporated, with a capital of $50,000, by A. M. Young, F. A. Stratton, and others.

Woodville, Miss.—See "Water."

Palestine, Tex.—The City Council is stated to have granted R. V. Gray, of Texarkana, a franchise for an electric light plant, a gas plant and an electric railway.

Covington, Ky.—The Union Light, Heat & Power Co. is stated to have secured the contract for furnishing arc lights at $75 per lamp per year.

Searcy, Ark.—See "Water."

Ardmore, Ind. Ter.—The Ardmore Electric Light & Power Co., of Guthrie, has been incorporated, with a capital of $40,000. Incorporators: A. Renmelli, St. Louis, Mo.; H. E. Foster, Ardmore, Ind. Ter.; Henry Braun, Guthrie, Okla. Ter., and others.

Brownsville, Tex.—F. L. Houston, of San Antonio, is reported interested in the construction of an electric light plant.

Eugene, Ore.—The Co. Comrs. are stated to have granted the Booth-Kelly Co. a franchise to erect poles and string wires for the transmission of electric power from Springfield to Eugene.

San Francisco, Cal.—The Humboldt Light & Power Co., of San Francisco, has been incorporated; capital, $100,000. Directors: C. P. Doe, E. Woodin, and others.

Seattle, Wash.—The following bids are stated to have been opened by the Bd. of Pub. Wks. Dec. 6 for lighting the city for one year: Seattle Electric Co. for enclosed arc lamps (66 amp. 78 volts), $66 each per year, and for 30 c. p. incandescent lights, $15 each per year; Seattle Gas & Electric Co. for furnishing any number of street lamps on the line of existing mains and care for the same at $2 a month per lamp.

Bridgewater, S. D.—W. E. Roosecrans is reported interested in the construction of an electric light plant.

Folsom City, Cal.—Brainard F. Smith, Clk. State Bd. of Prison Directors of Cal., writes that the following bids were opened Nov. 22 for furnishing the State prison at Folsom City with an electric light plant: General Electric Co., on 75-Kw. generators, etc., $6,775; Westinghouse Electric & Mfg. Co., on 75-Kw. generators, etc., $7,600; Stanley Electric Mfg. Co., care John Martin & Co., agents, San Francisco, 65-Kw. generators, etc., $6,615; also 90-Kw. generators, $7,490 (awarded).

Great Falls, Mont.—City Engr. C. W. Swearingen writes that a franchise for a gas plant has been asked by St. Paul parties. This city has no gas plant at present.

Ft. Morgan, Colo.—Messrs. Handy & Hale have petioned the Town Bd. for a franchise for an electric light plant.

Harrison, Idaho.—The Harrison Electric Light Co., Ltd., has been incorporated, with a capital of $10,000. Directors: L. J. Kimmel, H. O. Thompson and W. O. Wheeler, all of Harrison.

Logan, Utah.—The Hercules Power Co. is stated to have secured the contract for furnishing the city with 169 32-c. p. lights, at $219.10 per month.

Santa Clara, Cal.—The California Light & Fuel Co. is stated to have secured the contract for constructing a Lowe crude oil gas-making plant for the city, with a capacity of 3,000 ft. per hour; the plant will cost $33,000.

Salt Lake City, Utah.—See "Water."

Owen Sound, Ont.—The citizens are stated to have voted to acquire the gas and electric light plants, at a cost of $75,000.

Guayaquil, Ecuador.—Bids will be received until Feb. 12 by the Secy. of the Municipal Council of Guayaquil for lighting the city by gas or electricity. At least 1,400 gas or electric lights of 15.4 c. p and 50 80 c. p. arc lamps will be needed.

ELECTRIC RAILWAYS.

Concord, N. H.—The City Council on Dec. 13 granted locations to the Concord, Dover & Rochester St. Ry. Co. Wallace D. Lovell, of Boston, Mass., Pres. Union Electric Co. of Dover, N. H., is reported interested.

Worcester, Mass.—The Worcester & Northern St. Ry. Co. is about to be organized, with a capital of $150,000, to build and operate a street railway from the terminus of the Worcester & Holden St. Ry. at Jefferson, through Princeton, to the center of Westminster, where it will join the Fitchburg, Westminster & Gardner Street Ry. Incorporators: Stephen Salisbury, of Westminster; Henry W. Warren, of Holden; Dr. C. E. Parker, of Princeton, and others.

Providence, R. I.—The Senate has passed the bill incorporating the Providence & Burrillville St. Ry. Co. It will construct a line in North Providence, Smithfield, North Smithfield, and Burrillville. Edgar K. Ray, of Woonsocket, is one of the incorporators.

Bristol, Conn.—Engineers under W. A. Sperry, of New Haven, are reported to have begun work on the new trolley line from Bristol to Terryville. The line is to be owned and operated by the Bristol Tramway Co., and will cost about $80,000.

Fiskdale, Mass.—The Worcester & Southbridge Ry. Co. is reported to be considering the extension of its line 12 miles from Fiskdale through East Brimfield, Brimfield to Palmer, there to connect with the line to Springfield. W. H. Culver, Ch. Engr., Worcester.

Hartford, Conn.—The Hartford & Middletown Ry. Co. and the New Haven & Middletown Ry. Co. have been incorporated, with a capital of $3,000,000, to construct electric railways—one from Hartford to Middletown, the other from Middletown to New Haven. Incorporators: Chas. E. Perkins, Hartford; Frank D. Haines, Middletown; S. H. Wagner, New Haven, and others.

New York, N. Y.—The Bd. of Aldermen on Dec. 16 passed the ordinance granting the Pennsylvania R. R. Co. the right to tunnel under Hudson River to the Boro. of Manhattan, to the projected terminal of the company below 34th St. between 7th and 9th Aves., then eastward under East River to the Boro. of Queens, to connect with the Long Island R. R. system recently acquired by the Pennsylvania Co. The company proposes to spend $50,000,000 on the improvement. W. H. Brown, Ch. Engr., Philadelphia, Pa.

The Bd. of Aldermen also passed on Dec. 16 the franchise giving the New York & New Jersey R. R. Co. the privilege of landing its Hudson River tunnel at West St. This franchise is for a tunnel from New Jersey for a trolley line, the tunnel to strike Manhattan at the foot of Morton St. and to run up to Greenwich St. The plan of the company is to continue and complete the partly constructed tunnel under North River, work on which is now being prosecuted on the Jersey side.

The State R. R. Comn. is stated to have authorized the Union Ry. Co. of New York to use the overhead trolley system in extensions of its lines on several streets in the Bronx Boro.

Pleasantville, N. J.—The Atlantic City & Suburban Ry. Co. is stated to have secured a right of way in Pleasantville and Absecon.

Boyertown, Pa.—The Town Council has granted right of way to Trappe & Limerick St. Ry. Co.; this is the connecting link needed by the United Power & Transpt. Co., for continuous line from Reading to Philadelphia. J. A. Rigg, Pres., Reading.

Northeast, Md.—The Town Comrs. are stated to have granted a franchise to the Cherry Hill, Elkton & Chesapeake City Electric Ry. Co.

Elkton, Md.—The Elkton, Newark & Eastern Shore R. R. Co. is reported organized, with Joshua Clayton Pres., and Albert Constable, Jr., Secy. The company proposes constructing a trolley line between Elkton and Delaware City, by way of Newark, to connect with the Wilmington & Delaware City line now in operation. It also proposes extending its line down to the Eastern Shore of Md. The Vandegrift Construction Co. will probably be the contractors.

Hyattsville, Md.—The contract for erecting a power house for the Washington, Baltimore & Annapolis Electric Ry. Co. is stated to have been awarded to the Cleveland Construction Co. of Akron, O. The building, fully equipped with machinery, will cost about $300,000. The company is also reported to be taking estimates for a building to contain car sheds and machine shops at Annapolis; it will be of concrete construction, 180x60 ft., and cost about $25,000. Jas. Christy, Jr., Vice-Pres., Washington, D. C.

Newark, Del.—The Newark, Elkton & Eastern Shore Electric Ry. Co. is reported organized, with Joshua Clayton, Pres., and Albert Constable, Jr., Secy. The company proposes constructing a trolley road from Newark, Del., via Elkton, Chesapeake City and on down the eastern shore of Maryland.

Portsmouth, O.—S. P. Baird, Engr. in Charge, writes in regard to the construction of a new power house for the Portsmouth St. Ry. & Electric Light Co., that contracts for the electrical machinery and steam turbines have been let, but contracts for boilers, condensers, and buildings are still to be let. Cost, $150,000.

Lorain, O.—The Lorain & Western Electric Co. has been incorporated, to construct a trolley line between Cleveland and Lorain, a distance of 20 miles. Incorporators: Rev. A. B. Stuher, Geo. L. Cooley, Frank R. Lander, and others.

Cincinnati, O.—The Cincinnati, Dayton & Ft. Wayne R. R. Co., of Dayton, has been incorporated, with a capital of $1,000,000 to construct an electric railway from Cincinnati to Ft. Wayne, Ind., and to Toledo.

Hartford City, Ind.—The Co. Comrs. are stated to have granted a franchise to the Oil Belt Traction Co.

Vincennes, Ind.—The Western Indiana Traction Co. of Vincennes, has been incorporated, with a capital of $100,000, to construct interurban railways in Vanderburgh, Posey, Gibson, Knox, Sullivan and Vigo Counties. The company also has the power to furnish electric light and power. Directors: Edgar H. DeWolf, Chas. W. Benham, Saml. W. Williams, and others, all of Vincennes.

South Bend, Ind.—The Indiana Ry. Co. (Electric) is preparing to extend its tracks to Notre Dame, and have the line in operation in 1903. Jas. McM. Smith, Vice-Pres. and Gen. Mgr., South Bend.

Boone, Ia.—L. W. Reynolds is reported interested in the construction of an electric railway from Boone to Webster City and Fraser, a distance of about 65 miles.

Detroit, Mich.—The Detroit, Monroe & Toledo Short line has been incorporated, with a capital of $3,000,000. The Black-Mulkey Electric Ry. connecting Monroe and Toledo has been taken over and will be extended to Detroit. Of the capital, $1,000,000 is set apart for improvements. Stockholders: C. A. Black and J. M. Mulkey, Detroit; Arthur Hill, Saginaw; Matthew Slush, Mt. Clemens, and others.

Youngstown, O.—The City Council is stated to have granted a franchise to the Lake Erie, Youngstown & Southern R. R. Co.

Ripon, Wis.—The City Council is stated to have passed an ordinance granting the Madison & Northwestern R. R. Co. a franchise to construct, maintain and operate an electric railway line in Ripon.

Virginia, Minn.—The City Council is stated to have granted a franchise to the Missabe Electric Ry. Co.

Greenville, Miss.—It is stated that the Delta Light & Power Co. proposes constructing an electric railway 3½ miles long.

Beaumont, Tex.—The City Council is stated to have granted a franchise to the Beaumont, Port Neches & Port Arthur Electric Ry. Co.

Palestine, Tex.—See "Power Plants, Gas and Electricity."

Marion, Ala.—The City Council is stated to have granted the Marion Light & Power Co. a franchise to construct an electric railway.

Little Rock, Ark.—Local press reports state that the Little Rock Traction & Electric Co. will construct a new power plant, at a cost of $500,000.

Lincoln, Neb.—The Lincoln Traction Co. is stated to have decided to construct a large addition to its power plant. J. H. Humpe, Mgr., Lincoln.

Oregon City, Ore.—The City Council is stated to have granted a franchise to the Oregon City & Suburban Ry. Co.

Spokane, Wash.—Local press reports state that the Washington Water Power Co. is considering the extension of the Sprague Ave. line to connect with its Union Park spur, the construction of a new line from Ross Park west on Indiana Ave., and the construction of a double track steel bridge across Spokane River at Post St. D. L. Huntington, Mgr., Spokane.

Grass Valley, Cal.—The Bay Counties Power Co. is stated to have completed a survey for an electric line from Grass Valley to Colfax.

Oroville, Cal.—It is stated that bids are wanted Jan. 8 for the purchase of a franchise to construct and operate an electric railway over certain roads in Butte Co., as applied for by Fred. M. Clough. H. T. Batchelder, Co. Clk.

Seattle, Wash.—The Seattle & Everett Interurban Ry. Co. has been incorporated, with a capital of $1,500,000, to construct an electric railway between Seattle and Everett, a distance of 33 miles. Incorporators: M. D. Haynes, Jas. E. McMurray, and others.

Ottawa, Ont.—E. J. Walsh is reported to have commenced surveying for an electric railway for the Ottawa, Brockville & St. Lawrence Ry. It will be 55 miles in length.

RAILROADS.

Attleboro, Mass.—Plans for abolishing the grade crossings of the N. Y., N. H. & H. R. R. in Attleboro are reported as being under consideration. If the plans are accepted, it is stated that the Attleboro branch road of the Union Traction Co., which is now Probable cost of work is $400,000. C. M. Ingersoll, Jr., Ch. Engr., New Haven, Conn.

Williamstown, Mass.—The Hoosac Valley St. Ry. Co. is stated to have petitioned the State R. R. Comrs. for the abolishment of certain grade crossings in Williamstown, Adams and North Adams. W. T. Nary, Mgr., North Adams.

Washington, D. C.—See "Business Buildings."

Greenwich, N. Y.—The Battenkill R. R. Co., of Greenwich, has been incorporated, with a capital of $75,000, to operate a steam railroad 7 miles long from Greenwich to Schuylerville. Directors: G. F. Blandy and C. P. Noyes, of N. Y. City, and I. C. Blandy, of Greenwich.

Huntdale, N. C.—It is stated that the J. M. Brick Lumber Co. will construct 13 miles of railroad from Huntdale to a point in Yancy County, N. C.

Momence, Ill.—The Illinois, Iowa & Minnesota Ry. Co. has been incorporated, with principal offices in Chicago and a capital of $100,000. The new road is to be constructed from Momence through the counties of Kankakee, Will, Grundy, Kendall, Kane, De Kalb, Ogle, Winnebago, Stephenson, and Jo Daviess, terminating at East Dubuque, Ill.

Kenosha, Wis.—The Chicago, Waukegan & Elgin Ry. Co. is reported to be considering the construction of a steam railroad from Foxlake, Ill., to Kenosha. W. T. Arthur, Pres., Council Bluffs, Ia.

Elnora, Ind.—It is stated that the Southern Indiana R. R. Co. will extend its line from Elnora to Evansville, a distance of about 70 miles. J. W. Thompson, Gen. Supt., Terre Haute.

Cincinnati, O.—H. M. Strong, Hotel Sterling, Cincinnati, is desirous of securing bids for constructing 17 miles of double track railroad construction, from 23 to 40 miles from Cincinnati; most of it is very heavy work; portions of it have considerable loose rock. Approximately 2,500,000 yds. of material to be excavated. Transportation on outfit free from St. Louis, Chicago, Cleveland and other intermediate points; 60-lb. rails and frogs free. The work can now be inspected, and further information will be given by Mr. Strong.

Ravenna, O.—Drake & Stratton, of Philadelphia, Pa., are stated to have secured the contract for changing the line of the Cleveland & Pittsburg division of the Pennsylvania Lines West, between Ravenna and Hudson; cost reported to be about $650,000.

Grayson Springs, Ky.—The Illinois Central R. R. Co. is reported to have in contemplation the extension of its line from Grayson Springs Station, 20 miles southwest to Peonia, Ky. W. J. Harahan, Ch. Engr., Chicago, Ill.

Oliver Springs, Tenn.—The Callahan Construction Co. is stated to have secured the contract for the construction of the Oliver Springs branch of the Knoxville, LaFollette & Jellico R. R. (R. Montfort, Ch. Engr., Louisville, Ky.). The cost is reported to be about $200,000.

Haileyville, Ind. Ter.—The Choctaw-Rock Island R. R. Co. is stated to have decided to construct a line from Haileyville to Dallas, Tex., a distance of 100 miles. W. E. Dauchy, Ch. Engr., Chicago, Ill.

Vicksburg, Miss.—Press despatches state that the Natchez & Gulf R. R. survey (final) has been completed. The counties traversed are Adams, Franklin, Amite, Marion, Pearl River, Hancock, and Harrison.

Columbia, Miss.—A preliminary survey is stated to have been completed for a new line for the Gulf & Ship Island R. R. Co. from Mendenhall to Columbia, a distance of 50 miles. W. W. Vail, Ch. Engr., Gulfport, Miss.

Crockett, Tex.—P. A. McCarthy, of Kennard, Tex., Ch. Engr. of the Eastern Texas R. R. Co., is stated to have completed the preliminary survey for an extension of the line from Kennard to Crockett, a distance of 31 miles.

Granger, Tex.—The Granger, Georgetown, Austin & San Antonio Ry. Co., recently chartered to construct a railroad from Granger, via Georgetown to Austin, about 50 miles, will be operated by the Mo., Kan. & Tex. Ry. (S. B. Fisher, Ch. Engr., St. Louis, Mo.); it has been partially graded by the former Georgetown & Granger Ry. Co.; remainder of line will be located at once and contracts let for construction. C. B. Jones, Granger, Vice-Pres. and Secy.; A. A. Allen, of St. Louis, Mo., Pres.; T. S. Miller, of Dallas, Atty. Capital stock, $50,000.

Memphis, Tenn.—Bids are wanted at the U. S. Engineer Office until Jan. 14 for the construction of steel hull towboat and furnishing outfit for same, for use in 3d Dist., Improving Mississippi River, as advertised in The Engineering Record.

Jackson, Miss.—Bids are wanted Jan. 2 for completing the approaches, etc., at the U. S. Post Office and Court House, at Jackson. Jas. Knox Taylor, Superv. Archt., Treas. Dept., Washington, D. C.

South McAlester, Ind. Ter.—Press reports state that the Dept. of Justice is receiving bids for building 4 stone and brick federal jails, fitted with steel cells, bath rooms, heating and lighting apparatus, etc., in the territory, at South McAlester, Vinita, Muskogee and Ardmore. The 4, it is stated, are to cost $100,000, inclusive of the sites, and to be completed within 10 months from date of contract.

Chattanooga, Tenn.—The Secy. of the Treasury has recommended to be set aside $350,000 for improvements upon the Tennessee River. This makes a total of $550,000 that will be immediately available for the work upon Colbert and Bee Tree shoals canal.

Ft. Assinniboine, Mont.—Post Q. M. McDonald, of the 3d U. S. Cavalry, at Ft. Assinniboine, is reported to have received plans from the War Dept. for a sewer system for the Post, 4 new 2-story brick barrack buildings and a hot water heating plant for the officers' quarters. Amount allowed, $75,000.

Hot Springs, S. D.—The Bd. of Managers of the National Home for Disabled Vol. Soldiers has approved preliminary plans prepared by Thos. R. Kimball, of Omaha, Neb., for the sanitarium at Hot Springs and a resolution has been adopted asking Congress to appropriate $200,000 in addition to the $250,000 already appropriated for the completion of the sanitarium.

Denver, Colo.—The Flour City Ornamental Iron Wks. are reported to have received the contract for the ornamental iron for the U. S. Mint at Denver, for $31,000.

Ft. Meade, S. D.—The lowest bids for plumbing and heating in the new double barracks at Ft. Meade are stated to have been from J. P. Adamson, of St. Paul, at $6,970 for plumbing, and from Saxton & Philips, of Minneapolis, at $5,490 for steam heating.

Ft. Townsend, Wash.—Bids will be received by the Quartermaster until Jan. 6 for construction, including plumbing, electric wiring and heating several buildings at this post.

Ft. Lincoln, N. D.—The contract for constructing new buildings at this fort has been awarded to P. M. Hennessy, of Minneapolis, as follows: Captain's quarters, $20,817; lieutenant's quarters, $13,182; barrack building, $28,067; guard house, $11,350; bakery, $4,603; hospital steward's quarters, $4,166.

Los Angeles, Cal.—Bids will be received until Jan. 15 (readvertisement) for completing jetty at San Diego Harbor, Cal. Capt. Edgar Jadwin, Corps Engrs., U. S. A.

Chemawa, Ore.—Bids are wanted Jan. 15 for furnishing material and constructing a brick dormitory with plumbing, steam heat and electric light at the Salem School, Chemawa. W. A. Jones, Comr. of Indian Affairs, Dept. of the Interior, Washington, D. C.

Portland, Ore.—Bids will be received until Jan. 9 for erecting Brown's Point Light Station, Wash. Capt. W. C. Langfitt, Corps Engrs., U. S. A., Engr. 13th Light House Dist., Portland.

Haines, Alaska.—Bids will be received until Dec. 31 for constructing a wharf, approach, warehouse, etc., at the new Army Post on Portage Cove, Haines. Address Capt. W. P. Richardson, Constructing Q. M., Skagway, Alaska.

Cavite, P. I.—Bids will be received by Mordecai T. Endicott, Ch. Bureau of Yards & Docks, Navy Dept., Washington, D. C., until Mar. 14 for constructing a steel floating dry dock for the naval station at Cavite.

MISCELLANEOUS.

Providence, R. I.—Bids are wanted Dec. 23 for furnishing and delivering on the City Dock the cement needed by the city for its sewer, water, highway and bridge departments during the year of 1903, not to exceed 5,000 bbls. of Portland cement and 7,000 bbls. of natural cement. Robt. E. Smith, Comr. Pub. Wks.

The City Council has passed a resolution appropriating $5,000 for the improvement and development of Slater Memorial Park.

Boston, Mass.—Bids will be received until Jan. 1 by the Boston Transit Comn. for constructing a portion of the East Boston tunnel at the head of State St., and for making alterations in the Old State House. Howard A. Carson, Ch. Engr.

New York, N. Y.—Bids are wanted Dec. 23 for furnishing material and removing the 2 existing piers, and building a new wooden pier, with appurtenances, at ft. of E. 86th St., East River (not 68th St., as previously stated). McDougall Hawkes, Comr. of Docks.

Medina, N. Y.—A. L. Swett, Pres., writes that the A. L. Swett Iron Wks. propose to construct a dam near this village. Probable cost, $200,000. Engr. in Charge, W. A. Brackenridge.

Jersey City, N. J.—The Pennsylvania R. R. has been granted permission by the building inspector to erect a new pier at the foot of Grand St., a steel superstructure, covered with corrugated galvanized iron, to cost $45,000

Camden, N. J.—The New York Shipbuilding Co. is said to have under consideration the building of a $2,000,000 floating dry dock at its plant in Camden.

Brooklyn, N. Y.—Bids are wanted Dec. 24 for furnishing and erecting wrought iron picket fence along shore road and iron gates in New Lots and Linton Parks, for furnishing and delivering 6,600 cu. yds. of Hudson River road gravel in parks and parkways as required, for furnishing and delivering 6,000 cu. yds. of crushed trap rock and 3,000 cu. yds. of trap rock screenings on parkways, all in the Boro. of Brooklyn, for furnishing and delivering 7,550 cu. yds. of blue limestone and 6,700 cu. yds. of blue limestone screenings on parks and parkways in the Boros. of Brooklyn and Queens. Wm. R. Willcox, Chmn. Park Comrs., N. Y. City.

Bids are wanted Dec. 24 (readvertisement) for furnishing material and dredging Gowanus Canal, Wallabout Canal, East River, ft. of Division Ave. and Newtown Creek, ft. of Metropolitan Ave. Engineer's estimate of the quantity of material to be dredged is as follows (cu. yds., scow measurement): Gowanus Canal, 25,000; Wallabout Canal, 11,000; East River, 4,000; and Newtown Creek, 2,000. J. Edw. Swanstrom, Boro. Pres.

Savannah, Ga.—Local press reports state that the dry dock which the Savannah Dry Dock & Shipbuilding Co. proposes to build here will cost about $600,000.

Cleveland, O.—Press reports state that plans have been completed to enlarge the dock of the American Shipbuilding Co. at Cleveland, which is now 320 ft. long and 50 ft. wide, and make it 520 ft. long and 60 ft. wide.

Cincinnati, O.—The State Bd. of Pub. Wks., Columbus, on Dec. 9 opened bids for the contract of continuing the work of building retaining walls in the canal in and near Cincinnati, for which $61,000 has been appropriated by the Legislature. The lowest bid, which was from F. H. Kirchner & Co., of Cincinnati, is said to have been as follows: With water in canal, 30 cts. for excavation masonry, $5.50 and $7.50 for No. 1 and No. 2; concrete foundation, $3; concrete wall, $7.50, and slightly lower with water drained from canal.

Sandy Cove, N. S.—Bids are wanted Jan. 2 for constructing a public breakwater at Sandy Cove. C. E. W. Dodwell, Res. Engr., Halifax, N. S.; Fred. Gelinas, Secy., Dept. of Pub. Wks., Ottawa, Ont.

NEW INDUSTRIAL PLANTS.

The Mix & Riddell Hardware Mfg. Co., Stamford, Conn., will erect a 205x40-ft. factory, with a 100x40-ft. ell, both having three stories. The power plant will include 200 H.-P. in boilers and a 125-H.-P. engine.

The Nairn Linoleum Co., Kearney, N. J., will build a $50,000 addition to its works. Chas. P. Baldwin, 22 Clinton St., Newark, N. J., Archt.

The Portsmouth, O., Street Railway & Electric Light Co. will erect a new power house, to cost $150,000. Contracts for the electrical machinery and steam turbines have been let. Boilers, condensers and buildings are still to be contracted for. S. P. Baird, Engr. in Charge.

The Pacific Smelting Co., First National Bank Bldg., Bakersfield, Cal., will erect a 100-ton smelter, to be increased later to 500 tons. Oil fuel will be used.

The Reade Machinery Co., 410 American Trust Bldg., Cleveland, O., will erect a machine shop to be about 100x200 ft., and expects to go into the business of building light locomotives and repairing and rebuilding locomotives, railway and contractors' equipment, power plants and heavy machinery, in addition to the building of heavy punches and shears.

The Mesta Machine Co., Lewis Block, Pittsburg, has bought about 10 acres adjoining its present plant, which it expects to double. Plans have not yet been prepared.

J. E. Lonergan & Co., 211-213 Race St., Philadelphia, brass founders and finishers, have plans and estimates (which they regard as excessive) for a 5-story, 220x45½-ft. building. If it is decided to go on with the building, an engine of about 100 H.-P., 150 H.-P. in boilers, an electric light plant and electric motors will be required.

Alfred Wilson, Motley, Minn., is in the market for second-hand woodworking machinery. Power plant has been bought.

Pitts Bros., Hazlehurst, Miss., will install a 20-ton ice plant to be ready April 1.

The Ore Reduction & Smelting Co. of St. Louis, 309 Equitable Bldg., St. Louis, will erect an ore reduction plant in the vicinity of St. Louis, but the location has not been positively decided.

The Colorado Foundry Co., Pueblo, Col., has been organized with a capital of $25,000 for manufacturing gray and malleable iron castings. The 50x150-ft. foundry building is erected, and there will be machine shops of the same size, equipped with electric motors driven from long distance power. Hot-air furnaces of a new type, designed by the company's engineers, will be used in the foundry. O. P. Sells is interested.

The Bloch Brothers' Tobacco Co., Wheeling, W. Va., expects to erect an 8-story, 100x150-ft. building. The power plant will consist of two 150-H.-P. boilers and a 150-H.-P. gas engine and generator. Electrical transmission of power will be used.

The Manitoba Cement Co., Winnipeg, Man., has been incorporated with a capital of $1,000,000, and proposes to erect a plant to have a daily capacity of 1,000 bbls. The buildings will be fireproof, constructed of brick, cement and steel, and the plant will be electrically driven, direct current being used. The officers of the company are: Pres., Justus Chancellor; Vice-Pres., Wm. Whyte; Treas., Wm. Blackwood; Secy. & Mgr., J. A. Hunter.

The J. H. Horne & Sons Co., Lawrence, Mass., maker of paper mill machinery, contemplates erecting a 100x70-ft. addition to its foundry.

The Washington Pipe & Foundry Co., Tacoma, Wash., has purchased the plant of the Soderberg Pipe Co., and is remodeling it and installing new machinery for manufacturing pipe. The company is also about to install a foundry for making hydrants, gate valves and water-works fittings. A pipe factory is being erected at Spokane. The power is electrical.

BUSINESS NOTES.

The Ward-Corby Co., a branch of the Ward-Mackey Co., which operates large bakeries in Pittsburg, is erecting new bread and cracker bakeries in Chicago and Providence, each of which is to be supplied with 150-H.-P. boilers by the Pittsburg Gage & Supply Co. This company is also supplying the Pittsburg Tool & Drop Forge Co., Cheswick, Pa., with a 150-H.-P. water-tube boiler and the Windsor Hotel, Wheeling, W. Va., with a 65-H.-P. water-tube boiler.

The Wm. B. Scaife & Sons Co., Pittsburg, reports the following among recent orders for Scaife and We-Fu-Go water softening and purifying plants: Salem Iron Co., Leetonia, O., 2,500 H.-P.; Rochester & Pittsburg Coal & Iron Co., Dubois, Pa., 2,500 H.-P.; Toledo, O., Furnace Co., 4,000 H.-P.; Edward E. Rieck Co., Pittsburg, Pa., 500 H.-P.

The Ball Engine Co., Erie, Pa., reports the following among recent engine sales: McPherson, Kan., Water & Electric Works, 125 H.-P.; United States Coal Co., Dillonville, O., two 300 H.-P.

The Western Electric Co. reports gratifying results from its constant potential alternating arc lamps, which operate on the repulsion principle.

The American Blower Co., of Detroit, Mich., is building heating apparatus for the Iron City Sanitary Mfg. Co., Zelienople, Pa.; Enterprise Mfg. Co., Columbiana, O.; B. F. Lee Co., Braddock, Pa.; Monongahela, Pa., Forge & Furnace Co.; New York Glucose Co., Edgewater, N. J., and the Michigan Malleable Iron Co., Detroit.

The Otis Elevator Company's recent contracts include the following: Ten hydraulic passenger elevators for the extension of the Manhattan Life Insurance Company's building, 64-70 Broadway; eight hydraulic passenger and two hydraulic freight elevators for the Barclay Bldg., Broadway and Duane St., and four hydraulic passenger elevators for the store of Frederick Loeser & Co., Brooklyn.

Descriptive catalogues for filing, reference, and specification purposes are asked for by George Welsby Scott, consulting engineer, 758 The Rookery, Chicago, Ill.

The Engineering Record is published every Saturday at 114 Liberty Street, New York. Its opinions on technical subjects are either prepared or revised by specialists.

Subscriptions are received and single copies supplied by the International News Company, Breams Building, Chancery Lane, London.

The subscription rate is $5 a year for the United States, Canada and Mexico, and $6 for other countries in the Postal Union. Remittances should be made by check, New York draft or money order in favor of The Engineering Record. No responsibility is assumed for payments made otherwise, except those for subscriptions to the International News Company.

The Lake Ontario Route for the Barge Canal.

The agitation for the improvement of the Erie Canal has passed through many stages until it is proposed to make the new prism seventy-five feet wide on the bottom with water deep enough to float a barge one hundred and fifty feet long, twenty-five feet wide and drawing ten feet, which means a depth of water of twelve feet. While there are strong advocates of a ship canal between Buffalo and tide-water at New York City, it is generally conceded that the most judicious plan of improvement is that which contemplates the barge canal, the barges to have a carrying capacity of about one thousand tons. The dimensions of the prism have been reached after no little consideration and much argument. The settlement of questions relating to the size of the prism, however, does not mean the solution of the problem.

The Erie Canal is a true canal from Buffalo to Troy. While it parallels Lake Ontario it lies wholly within the land of the State. It was originally intended not only for the transportation of merchandise from Buffalo to the Hudson River, but also for such shipment of freight as might be demanded by the development of the cities and towns along its line. Its influence on the growth of these cities and towns and the development of land values from one extremity of it to the other is so clear that no doubt whatever attaches to that feature of its history. If a portion of its line, from Olcott, for instance, to Oswego, a distance of one hundred and twelve miles, had been laid in Lake Ontario, ignoring for the moment the effect of storms, it is absolutely certain that the interior development of the State would have been long deferred, and the general prosperity seriously checked. No such installment of the canal could, of course, have been considered for a moment when the canal enterprise first took effective shape.

The conditions bearing upon the improvement of the canal are obviously vastly different at the present time from those attending the original construction, yet it is well to give careful consideration to the proposed Lake Ontario route from the same points of view that would have been taken in the earlier construction. The proposition to run the line of the improved or barge canal from Troy to Oswego, then through Lake Ontario to Olcott or even to some point in Niagara River has been thoroughly canvassed by every engineer and every competent body of men who have had before them the problem of determining the best route. During 1900, when routes and other features of the improved waterway were being so carefully studied by the State engineer and by the consulting engineers and the advisory board, this line received serious attention and its advantages and disadvantages were fully recognized. Obviously it saves considerable cost of construction inasmuch as for a distance of about one hundred and twelve miles the open water of Lake Ontario is available. This is so attractive a feature that Governor Odell has given it his approval, and is apparently prepared to use his official influence for its adoption. Its attractiveness, however, is not without an accompaniment of material disadvantage even as a canal route aside from any other consideration. The waters of Lake Ontario are not always smooth. It is a lake of many storms and of sufficient roughness to endanger the safety of small vessels. It is true that it is not the Atlantic Ocean, but it is equally true that for a considerable portion of the open season it could not be navigated by such barges as could be used to advantage on an improved canal whose line would lie approximately along the present Erie Canal route. If barges are to be constructed of sufficient strength to make lake navigation safe their cost will be greatly enhanced and the dead weight of the boats will be so increased as to trench seriously upon their carrying capacity. In other words, the cost of construction will be greatly augmented and their carrying capacity decreased. Both of these elements will add materially to the cost of transportation. Again, barges will necessarily be towed in fleets of probably four or five. Under such circumstances, being without their own power, they must keep in protected harbors during storms. All these disadvantages would be heavy handicaps, and would make the transportation both costly and intermittent. The project of the improved waterway, whatever its route may be, must be submitted to the citizens of the State for their approval or disapproval in the election prescribed by the State Constitution. This feature of the subject is political and not engineering, and yet it is a feature of gravity, and one that must not be ignored. From Syracuse to Lockport the cities and towns otherwise benefited by location upon the improved waterway would be entirely avoided by the lake route, receiving practically no benefit from the enlarged canal. It does not require a very astute politician to determine in advance what sort of an expression would be given by the people thus affected. It may be stated with considerable reason that the main object of the canal would be the transportation of through freight, yet it is a fact now as it was eighty years ago that the interior cities and towns and the country adjoining the line will be materially benefited by the construction of the barge canal in consequence of local transportation facilities as well as the indirect advantageous effects of a current of traffic passing to and fro through their midst. While the State would be saved the sum perhaps of $20,000,000 in construction, in the eyes of the people immediately affected at least, it would lose far more by depriving so large a portion of its industrious population of the benefits of the improved canal.

Even this, however, is not all, as was clearly recognized by the advisory board of engineers acting during the year 1900, when the whole subject was receiving such careful investigation. If canal traffic between Buffalo and the Hudson River requires the construction of boats for its accommodation sufficiently seaworthy to navigate the waters of Lake Ontario there is little or no reason why they should not carry grain and other freights intended for ocean steamships directly from Buffalo to Montreal or to Quebec. Our Canadian neighbors are alert enough to discover and appreciate the advantages of such shipment along by far the shortest line between the Great Lakes and the ports of Great Britain and Europe. The construction of the barge canal therefore on the Lake Ontario route would be a direct and material encouragement toward the shipping of through freights from the Great Lakes down the St. Lawrence to Atlantic steamers, taking cargo at Montreal and Quebec. This would mean the diversion of a large amount of ocean shipments from New York City, which is already suffering at least considerable relative diminution of that traffic. The saving of $20,000,000 expenditure to the State of New York is certainly a material item, and one that should not be hastily overlooked, but it is by no means impossible that if the avoidance of that expenditure is both to increase the cost of canal transportation between Buffalo and tide-water and decrease the capacity of the barge canal, as well as encourage the diversion of ocean shipments from the port of New York to Canadian ports, the expenditure of a far larger sum to produce opposite results would be the highest degree of economy for the State.

Limited Franchises.

That the reasonable control of valuable franchises dealing with at least one line of public service is being gained by one of our leading cities will be evident after reading the brief article printed elsewhere in this issue on Boston's underground railways. The contract entered into by the city, acting through the Boston Transit Commission, and the elevated railway company can hardly be considered an experiment, for it is not the first agreement of such nature made by the same parties. It is, rather, an evidence that the contract previously made for the use of the existing subways, which has now been in force for several years, is proving satisfactory to the citizens and is not intolerable to the railway corporation. By the method pursued, the city does not merely build its subways and tunnels and retain the ownership of them, which facts in themselves have certain distinct advantages, but it receives an annual income of 4½ per cent. on its investment, has some measure of control of the structure during use, and can, at the end of twenty-five years, readjust the terms of the lease or become possessed of the equipment and operate the system. In this way municipal control is made effective by actual municipal ownership and potential municipal operation. Such advantageous arrangements in connection with public utilities are possible largely because of an unusually intelligent and public-spirited interest in public affairs among a large proportion of the citizens. A wise and successful solution of public as well as of private problems can be attained only through painstaking and intelligent study by capable men. These duties now frequently fall to engineers acting as city engineers, members of public works commissions or as engineers to such commissions and departments, and require not alone good technical efficiency and wide experience, but in a high degree, a broad-minded view and strong grasp of facts relating to men and affairs. That the value of engineering training and experience in fitting men for such service is being recognized is made plain by recent appointments in more than one large city.

A New Dam and Storage Reservoir at Amsterdam, N. Y.

The Glenwild reservoir, completed during the past summer, forms a part of the water-works of the city of Amsterdam, N. Y. It is located on Steele Creek, about two miles above the Hans conduit diverting dam, from which the water passes to the city. The area of the watershed of Steele Creek above Glenwild reservoir is 4.54 square miles. The entire watershed of the creek is without human habitation. It is all a forest of second growth spruce and hemlock, with beech, birch, maple and poplar trees, and will probably always remain uninhabited, as the soil is a glacial drift of sand and boulders, and totally unfit for cultivation.

An old mill pond formed by a low timber dam formerly occupied the site of the reservoir, and after the old dam had been removed, it was necessary to clear off all the old timber, stumps and debris on the site of the old pond, which covered 78 acres. The remainder of the basin was cleared off to an average width of 75 feet beyond the flow line. All small trees and brush were required to be cut down level with the ground, and all large trees so that the stumps should not project more than a foot above ground. The total area of the new reservoir is 180 acres and its capacity 1,200,000,000 gallons.

Glenwild reservoir dam is curved, the length of the chord of dam being 408 feet, and the versed sine of curve 30 feet. The dam is 450 feet long over all including tangents and is 13 feet wide on top with rear slope 2½ to 1 and front slope 2 to 1. The water face of the dam is protected with stone pavement, hand laid, the stones being from 10 to 24 inches deep and averaging 18 inches thick. The top of the dam is 7 feet above flow line, allowing ample depth for wave action. The rear slope is seeded.

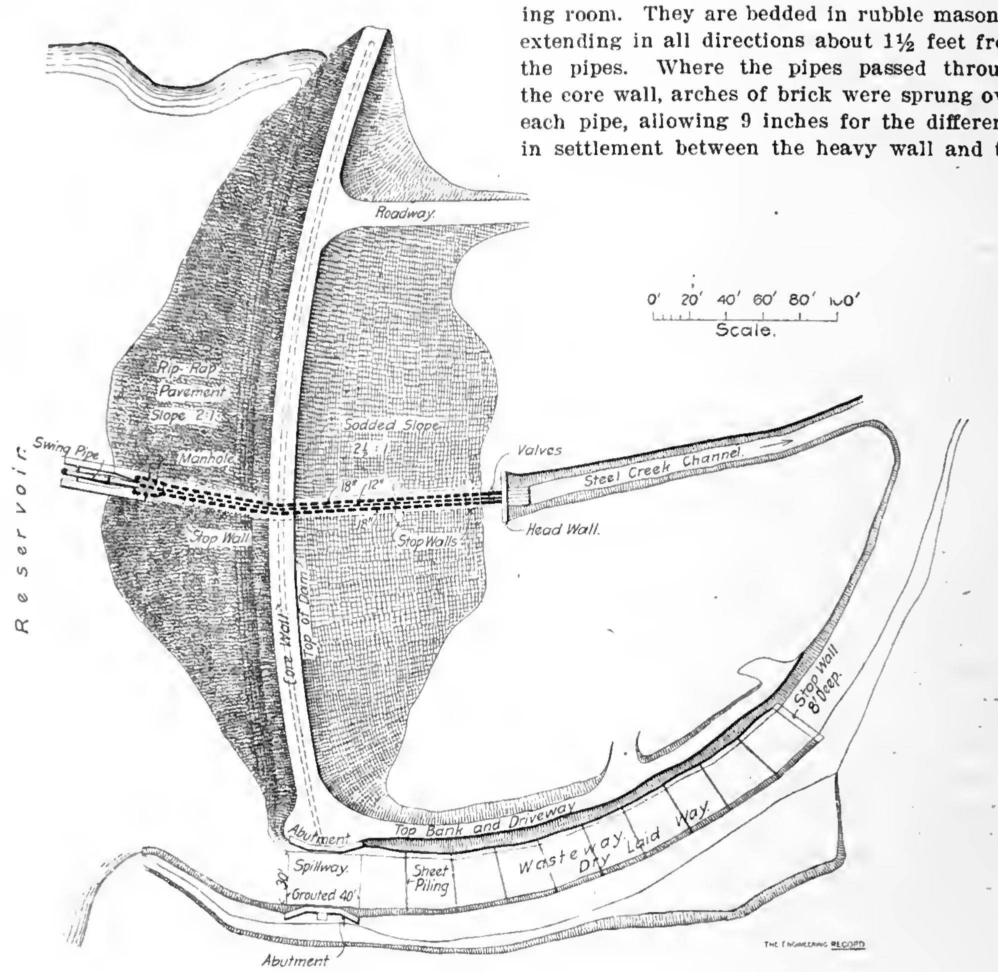
The spillway is 30 feet wide and 40 feet long, with the bottom paved with thin quarry stone set on edge and grouted. The wasteway, as well as the spillway, was formed by excavating back into the side hill, the material so excavated being used to make reservoir bank. The spillway has first-class rubble masonry abutments and wings coped with limestone. Beyond the spillway the channel, bottom and 4 feet up the sides, is dry paved with large stone averaging about 2 feet square on top face, and a line of sheet piling 4 feet deep was placed across the spillway channel and up the sides at every 25 feet, thus preventing any movement of the stone pavement. The lower end of the spillway channel is secured by a rubble wall in cement, 4 feet wide and extending down 8 feet below the pavement, the latter terminating at this wall.

It was impracticable to sink test pits at the old timber dam on account of its construction and the existence of the large amount of water there which could not be drawn off. It was assumed that rock bottom would be found at a depth of 5 to 6 feet below the level of the bottom of old timber dam or at least suitable hard bottom found, and the preliminary estimate upon which the contract was based was made upon this assumption. Such, however, proved not to be the case, but upon removing the old timber dam it was found to be bedded on rubbish and gravel and large fallen trees at least 10 feet below the base of the old dam were removed. Upon excavating for the masonry core wall down to the depth called for by the plans the bottom was found to be quick sand and entirely unsuitable to start the masonry from. The excavation was continued down some 22 feet, all through sand, until a stratum was found so compacted, as indicated by driving down a crowbar, as to be practically impervious to water, and the wall started on this bottom.

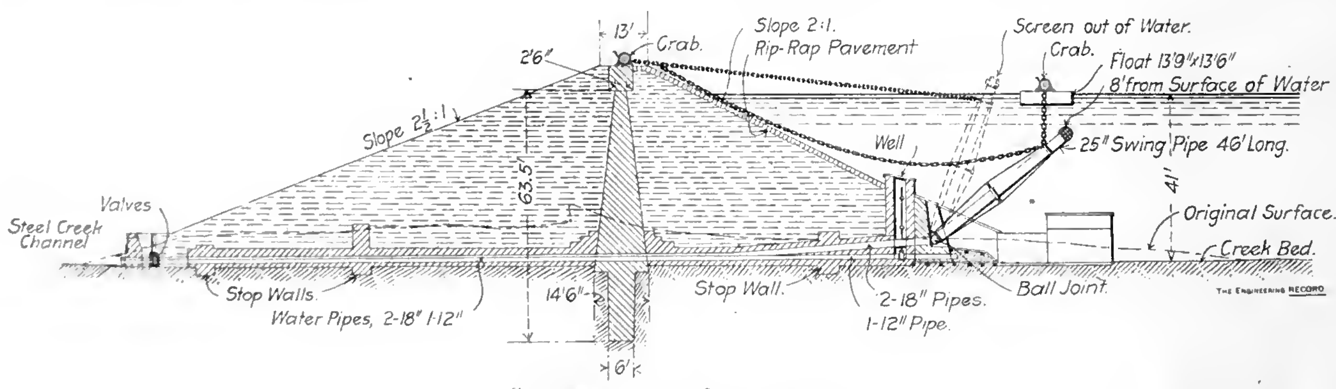
The cement masonry core wall starts 1 foot above the flow line and batters 3 inches to the foot down to a width of 14 feet 6 inches. Below this point it is 6 feet wide to the bottom. The wall is 63.5 feet high, and is composed of broken boulders, no stone exceeding ½ a cubic foot in size, all hand laid in place. The wall is grouted with a 1 to 3 mortar made of Glens Falls Portland cement. The grout was manipulated in small boxes holding only a wheelbarrow of mortar. The mortar box was dumped over the wall by two laborers, allowing all its contents to enter the wall at once. By this process the cement and sand have no time to separate, but are placed in the wall all thoroughly and properly mixed. The wall was grouted in 16-inch courses. At two places the wall was examined for depths of 4 and 6 feet, and in each case it was found all thoroughly filled and the mortar homogeneous.

Water is drawn from the reservoir by three lines of cast-iron pipe, two 18 and one 12-inch. These three pipes are laid side by side, with a space between of about 1½ feet to allow caulking room. They are bedded in rubble masonry, extending in all directions about 1½ feet from the pipes. Where the pipes passed through the core wall, arches of brick were sprung over each pipe, allowing 9 inches for the difference in settlement between the heavy wall and the masonry surrounding the pipes. Three 1½-inch wrought iron pipes were carried up in the center of the core wall to the top, and when the wall and embankment were completed and had reached their final settlement, grout was poured into the pipes and the arches below filled up solid.

The outlet pipes are continued on to the base of the front embankment and rip-rap wall, at which point a bulkhead and side walls are built. The lower or 12-inch pipe terminates at an elevation of 41 feet below the flow line. The reservoir may be drawn entirely dry with this pipe. At a distance of 36 feet back from the end of the 12-inch pipe the two 18-inch pipes rise on a steeper grade, so that at their ends the bottoms of the two 18-inch pipes are about 2



PLAN OF GLENWILD RESERVOIR DAM.



SECTION THROUGH OUTLET PIPES.

feet above the level of the top of the 12-inch pipe at its termination. The two 18-inch pipes terminate with two right angle bends facing one another. At this point a 25-inch steel riveted pipe begins, having a tee on its end which enters both 18-inch bends. This makes a swivel joint at the end of the 25-inch pipe. The swivel is made ball-bearing, by placing 56 brass balls in each bearing end of the 18-inch bends. The 25-inch pipe is then extended out into the reservoir 39 feet, and has a large ball screen on its end. A chain is attached to the outer end and toggled in at the center of a float 13x13 feet by 4 feet deep. The chain will usually be so toggled in the center of the float as to leave the outer end of the pipe suspended 8 feet below the surface of the water in the reservoir. As the water rises and falls in the reservoir the outer end of the pipe moves up and down a corresponding amount. The float is guyed by five wire cables securely fastened to anchors in boulders, out about 100 feet from the float. Provision is made for hoisting and lowering the 25-inch pipe by 10-ton crabs, one on the top of the dam and one on the float, a second chain cable being led up to the top of the bank. It is intended to lower the pipe in winter and rest it on a timber support near the bottom.

The valves which control the discharge of water are located at the lower end of reservoir embankment at the end of the sodded slope, discharging into the old channel of Steele Creek. The 12-inch pipe also has a valve located just back of its upper end with a well and valve rod carried up 20 feet above the bottom of the reservoir so that in case of repairs needed to the lower valve this upper one may be shut down when there is 20 feet of water in the reservoir. The end of the 25-inch pipe may also be swung up out of water to shut off flow through the two 18-inch pipes.

When the reservoir is drawn down and there is only sufficient water to cover the pipes, the two 18-inch pipes will discharge 15,000,000 gallons per day, while the 12-inch pipe will deliver 3,000,000 gallons. With the reservoir nearly full the three pipes will discharge upwards of 80 million gallons per day. Just below the dam a measuring weir with indicator arranged on a plank has been placed, so that the keeper can tell by inspection how much water is being delivered.

A dyke 460 feet long about half a mile from the dam was constructed across what was apparently an old lake outlet. The dyke is of varying height, from 3 to 15 feet. The top is placed 3 feet above the flow line of the reservoir. Should a cloudburst occur and be of such magnitude as to tax the capacity of the spillway at the dam then the dyke would act as a relief spillway 460 feet long after the water is 3 feet or thereabout above flow line. The dyke is 15 feet wide on top with side slopes of 2 to 1 on both sides. Through the center a double row of 2-inch sheet piling is carried from the top bank down 4 feet into the firm subsoil or hard pan formation. The dyke is in a cove and the wave action will be a minimum.

Upon filling the reservoir last spring, the cranberry bushes and logs, trees, stumps and debris rose up with the water and now constitute a series of floating islands out in the middle of the reservoir, and distant about 2,500 feet from the dam. The floating islands aggregate about 6 acres in area, and from soundings with a boat oar, are from 2 to 6 feet deep or thick. They seem to be composed of living cranberry bushes, held afloat by logs and old trees, and are anchored safely in place, probably by a number of old dead, but sound trees, the tops of which are tied in with cranberry bushes, the roots and stumps on the bottom making a safe anchorage. The early removal of these floating masses has been strongly recommended.

The Glenwild dam was designed by Mr. Stephen E. Babcock, of Utica, as consulting engineer, from whose report to the water commissioners of Amsterdam, the preceding account has been mainly taken. Mr. James R. Snell is superintendent of the Amsterdam waterworks. The work of construction was performed by Messrs. H. B. Hooker & Son, of Rochester, at a cost of $47,360. Including the cost of the land, clearing the site, etc., the total cost of the reservoir was about $65,000.

The Two-Hinged Arch.

By Edward Godfrey, 400 Monongahela Bank Building, Pittsburg, Pa.

A two-hinged arch is a trussed frame or a girder in the shape of an arch with two hinges or pins at the end supports or abutments. A difficulty in finding the stresses arises from the fact that the horizontal reaction depends upon the stiffness of the truss itself. The horizontal reaction may be supplied either by the abutments of the arch or by a tension member of steel forming a sort of bow-string for the arch. When the abutments supply this reaction, they

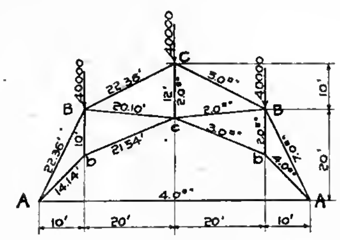


Fig. I

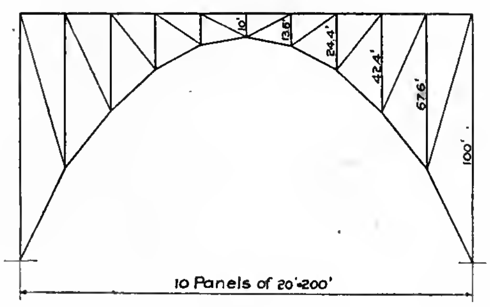

Fig. 2

must be assumed at an unvarying distance apart; that distance is the normal length of the unstressed arch at the temperature at which it was erected, or, say at a mean temperature. When a steel tie supplies the horizontal reaction, it will, if exposed to the same variation of temperature expand and contract with the arch itself; temperature stresses will then not enter into the computations. Cases may arise, however, where the tie is buried or protected from the sun's rays by the floor of a bridge, so that the difference of temperature of the arch and the tie may be considerable.

There are several methods given by various writers for finding the stresses in a two-hinged arch, all of which seem to be very tedious, difficult of application and practically impossible to retain in the memory. The writer proposes an analytic method which he believes renders the calculation simple and direct, and which is easily remembered, although, of necessity, the calculations are long.

The method is based on the "pull over E" formula, that is, the formula for finding deflections. Its application will be described first in finding the stresses in an arch assumed to be already proportioned. The formula referred to is:

$$D = \frac{\Sigma\, pul}{E}.$$

In this formula D is the deflection in inches of any point of a frame in any assumed direction, under any given condition of loading; p is the stress in any member of the frame due to a load of one pound applied at the point whose deflection is to be found, the load acting in the direction in which the deflection is to be computed; u is the unit stress, or stress per square inch, in the same member resulting from the given loading; l is the length of the member in inches; E is the modulus of elasticity of steel or 29,000,000 pounds per square inch. For each member in the frame the quantity pul over E must be found, and the algebraic sum of all will be the deflection sought; or the division by E may be made after the summation Σ pul has been found.

An example will best illustrate how this formula may be applied. Given the arch in Fig. 1, having areas and length as indicated and loaded as shown. Suppose the tie AA to be omitted, and we shall have a simple truss with stresses easy of computation by the ordinary analytic method. Under these stresses the points A and A will separate a certain amount, due to the deformation. The amount of this deformation, or the deflection at A may be found by the deflection formula. By applying a load of one pound horizontally at A and finding the resulting stresses in the various members, we shall have the values of p in the formula. The unit stresses resulting from the loads acting on the frame as a simple truss will give the values of u. The horizontal deflection at A is shown in table I to be 3.744 inches.

To bring the point A back to its original position, a force may be applied at A in a horizontal direction. The amount of the force thus applied necessary to move the point A 3.744 inches can be found in the following way: Assume a force of 1,000 pounds applied at A, and by the deflection formula find the resulting deflection. The values of p will be the same as before and those of u will be the unit stresses due to 1,000 times the p values for the various members. The deflection due to this force of 1,000 pounds is found by Table I to be .1015

TABLE I.

Stresses in Arch with Fixed Abutments. All Stresses, Except in Column 4, in Thousands of pounds.

Resultant deflections							3.744		.1015		

inch. Hence to restore the original distance between points A a horizontal force of

$$1000 \times \frac{3.744}{.1015} = 36900 \text{ pounds}$$

is necessary. This would be the horizontal reaction of this truss if the ends were fixed, as by stone abutments. The stresses in the member due to this horizontal reaction are found by setting on the slide rule the ratio 1:369000 and reading the amounts from column 4. The resultant stresses in the members are then found by combining the stresses in Columns 6 and 11.

If, as in the case under consideration, a tie AA is used, this tie will stretch out a certain amount, due to its own stress; and point A, instead of being brought back to its original position, will return the 3.744 inches less the stretch in the tie. The problem then arises to find the stress in the tie that will stretch it a distance x, which stress will just balance the force applied to the frame at A that will deflect it a distance y, where $x + y = 3.744$ inches. A force of 1,000 pounds on the tie, or 250 pounds per square inch, will stretch the tie $\frac{250 \times 720}{29,000,000} = .0062$ inches. Hence, letting H equal the stress sought in thousands of pounds, we have $.0062\ H + .1015\ H = 3.744$ inches, or $H = 34.8$. The new horizontal reaction is then 34,800 pounds. As before, with this horizontal reaction, the resultant stresses in the members can be found.

For temperature stresses in a two-hinged arch, assuming the arch to be put up at mean temperature, a variation from this of, say, 75 degrees each way should be provided for. For a rise or fall of temperature of 75 degrees a steel frame will tend to lengthen or shorten one-two-thousandth of its length. If the end supports are fixed in position, this lengthening or shortening of the frame is prevented. The result on the frame is equivalent to applying a horizontal force at the abutments that will give a deflection either way of one-two-thousandth of the length of the span, or in this case, .36 inch. The amount of this horizontal force as well as the stresses resulting therefrom may be found in the way described in treating the stresses caused by the vertical loads. Each piece will have equal positive and negative stresses. In cases where the tie is kept at a more uniform temperature, the assumed difference between the temperature of tie and frame will give the basis for determining the horizontal force and the temperature stresses.

When only the outlines of the arch are known and the members are to be proportioned, of course the method above outlined will require modification. The deflections cannot be found until the sections of the members are known, and the sections cannot be fixed upon until the stresses are known. Some assumption is therefore necessary. In all methods of finding the stresses in a two-hinged arch, some assumption seems to be necessary, since the change in the area of the cross-section of one member of the arch will alter the stress in every piece. In a paper written by Mr. A. R. McKim and published August 24, 1899, the assumption used to obtain the first trial areas is that the effect of the web members may be neglected in allowing for deflections. The arch treated in that article is shown in Fig. 2.

For finding the first trial areas an average area was assumed for both chords. The present writer applied the "pull over E" formula, taking the dead load stresses and the areas given in that article, and found that not only did the deflections due to chord stresses alone fail to balance, but the deflection due to the web members was all in the same direction and in amount was more than double that due to one chord and nearly seven times that due to the other. The resultant deflection was found to be over three inches, representing an error of 45,000 pounds in the horizontal reaction. Again it was found that, taking the areas given in that article and finding the dead load stresses by the method outlined above, scarcely any agreement was found with the dead load stresses in the same article. Some of the stresses were of a contrary sign. This is not given in criticism of the article referred to nor the method employed; that method would no doubt gravitate to the same final result as the one here given, if the effect of the web members in causing distortion be taken into account.

In the paper on the Rio Grande Bridge, in The Engineering Record, November 8, 1902, Mr. Aus states that there were eighteen diagrams needed to find the partial horizontal reactions, being the number of chord members in one-half of that arch. This would indicate that he, too, ignores the effect of the web members in causing deflection. This is manifestly incorrect, as any member which is subject to stress by a force applied in the position of the horizontal reaction will by its lengthening or shortening cause a deflection at the support; or, if the support be fixed in position, the member in question will have its effect in determining the amount of the horizontal reaction.

The assumption proposed here is this: The stresses found in the frame, considered as a simple span, will be much in excess of those considering the horizontal reaction. Suppose these stresses are double the actual stresses and assume that the average unit stress is, say, 10,000 pounds per square inch, or on these greater stresses 20,000 pounds per square inch. This will afford a basis for finding the horizontal reaction and trial stresses. While this is only an assumption, errors made will not be cumulative, but will balance more or less with other errors. The only thing that depends on this assumption is the amount of the horizontal reaction. If a uniform and not a rolling load is to be provided for, areas may be again found, based on the resulting stresses found by using the horizontal reaction thus obtained. Tentative proportions of the members should then be found and their areas tabulated, as conditions are often such that the actual area used in a member is several times that required, in order to use standard shapes and uniform details. With these areas a second trial for the horizontal reaction should be made and the areas adjusted to suit the new resulting stresses.

As a criterion for judging of the amount of error in the writer's assumption, the amount of the horizontal reaction for dead load stresses was found, using the areas in the article heretofore referred to, and it was found to differ by less than one per cent. from that found by trial areas at 20,000 pounds per square inch under total dead and live load as a simple span.

An advantage in this method of treating the two-hinged arch is that the stresses found are consistent with the areas used, and the calculated deflection at the abutment is just zero, including the effect of all members of the chords and webs. For a rolling load, that is, a live load that may be on any one of the panels of the arch, the method is just the same, but each load must be considered in its effect on the entire frame. It is best at the outset to find the stresses in all members due to a panel load of say 10,000 pounds, or the actual live load panel load, and to use combinations of these for the full live load, finding by the proper ratio the dead load stresses.

An arch of this sort will, in general, be stiff throughout, that is, with no rods, but all members counterbalanced. After finding the stresses due to the full dead and live load, the members should be given trial areas, the shapes being selected to suit the lengths of members and the details to be used, employing, say, a unit stress of 5,000 pounds per square inch. Then a live load is placed at one of the panel points and the stress in every member found, considering the truss as a simple span. Next the horizontal deflection at support is found, and the horizontal reaction to overcome this deflection. The resulting stresses due to this horizontal reaction are next set down and combined with those previously found (those due to the single panel load acting on the frame as a simple truss). This will give the stresses in the members due to this one panel load.

This must be repeated for each panel load and the result tabulated. The next step is to pick out the live load stresses of each sign in each member and to combine them with the dead load stresses, thus finding the minimum and maximum stresses. An adjustment of the areas required, based on the unit stresses given in the specifications, should then be made, and further refinement effected by repeating the whole operation. After once finding the stresses due to each panel load in every member and those due to one pound applied horizontally at the support, then the quantity $\frac{p\ l}{E}$ for each members, the labor involved in adjusting the areas and stresses is small. The quantity $\frac{p\ l}{E}$ will be the same for any member for all operations. One thousand times this quantity should be used to avoid long decimals, and then if the stresses be given in thousands of pounds, and unit stresses the same, the coefficient omitted in u will cancel that introduced in $1{,}000 \frac{p\ l}{E}$ giving as a product $\frac{pul}{E}$, or the partial deflection for the member considered.

Any reasonable assumption, or even sections proportioned at random, by one having sufficient experience to judge what is required, will serve as a basis for finding the stresses. Then on the basis of these stresses new areas may be found; and from these the stresses again computed. Thus any desired degree of accuracy may be obtained. By thus working over the areas and stresses any errors made will in all probability be eliminated, whereas in blindly following a complex formula only extreme care can be relied upon to prevent errors.

The Fire-Resisting Properties of Transformers was illustrated in a fire which broke out in the powerhouse of the Helena Light & Traction Co., at Helena, Mont., October 20, and completely demolished the building and nearly all of the machinery, the exception being a number of oil-insulated transformers, which were practically uninjured. In the case of two transformers, which were not overturned, the oil did not burn away sufficiently to injure their coils or cores. It is believed that it would not have ignited at all had not the covers been removed from the cases before the fire to facilitate cooling, the transformers being worked at a heavy overload. Four other transformers were standing on a wooden floor, and as soon as the latter burned away, they were upset and poured their oil into an engine pit below. The building originally contained a steam plant, but this had been abandoned and power was being purchased from the Missouri River Power Company. Three oil-insulated Westinghouse potential regulators in cast-iron cases, located behind a marble switchboard, which was destroyed, were found practically uninjured. Two 100-horse-power induction motors only somewhat damaged.

Compressive Resistance of Concrete-Steel and Hooped Concrete.—II.

The first five sections of this translation from M. Considère's original paper appeared in the preceding issue.

VI. *Spacing of Hoops.*—While testing prism B, cracks appeared under the light load of 1,730 pounds per square inch, and soon after the concrete began to chip off and finally failed between the spirals which served as hooping. These spirals were 1.18 inch apart. The failure of the prisms, which took place under a pressure of 5,120 pounds per square inch was due to the failure of the concrete and there was nothing to indicate that the metal had reached its elastic limit. In prism C whose spirals were only 0.59 inch apart the cracks did not show before a pressure of 2,480 pounds per square inch was exerted. Chipping occurred also later than in B and under a pressure of 5,400 pounds no failure of the concrete was observed, and the prism did not fail. In D and E cracks appeared under pressure of 2,900 to 3,360 pounds per square inch. These prisms contained, besides the same spirals as B and C, longitudinal rods, which were in contact with their interior surfaces, and formed with them a network which efficiently resisted the lateral failure of the concrete. Computations prove that the superiority of D and E, in this respect, considerably surpasses the resistance which could have been offered by the longitudinal rods alone. Connecting these facts to the figures given in the above table and to the observations made on other series of experiments, certain conclusions are arrived at as to the results obtained on the subject of the spacing of hoops and longitudinal reinforcing rods in contact with the inside of the hooping.

When the spacing of the spirals did not exceed 1/5 the diameter of the prisms, resistances were obtained almost independent of this spacing. *The facts mentioned and others which have been observed lead to the adoption of a spacing of the spirals of 1/7 to 1/10 the diameter when longitudinal reinforcing rods are added.* Experiments on prisms of quite different dimensions have proved that the above ratio holds true almost independently of the absolute values of the dimensions. The following consideration will explain it: If, taking the simplest case, the spirals are replaced by continuous hoops extending between planes perpendicular to the axis, the deformation which the continuity of hooping will indirectly prevent will consist of the swelling of the little cylinders enclosed between the tangent planes of the spirals. If the end pressure which is exerted on two similar prisms of different diameters has the same unit value, the lateral pressure required to prevent swelling will, in all probability, also have the same unit value. Such is certainly the case with sand. The total value of the lateral pressure will, for the small cylinders considered, be proportional to their sections along a diametral plane which is equal to the product of their height by the diameter, that is, to the square of the diameters since the prisms are similar. The hoops will offer this resistance to swelling, but it can only be transmitted from the metal to the small cylinders by the friction and cohesion acting on their bases whose areas are also proportional to the square of the diameter.

If two cylinders of different diameters are considered, all dimensions of which are proportional to each other, the shearing stress which will be produced in the planes tangent to the hoops will have the same value when the unit pressure on the prisms are the same. In other words, prisms of proportional dimensions behave the same way under the same unit pressures and it seems to be justifiable to express the rules as to the dimensions of the hooping element as a function of the ratio of these dimensions to the diameter, as was done above.

VII. *Ductility of Hooped Concrete.*—A removable metal tube 7½ inches in diameter was filled with Portland concrete and bent to a radius of curvature, of the neutral line of 21.6 inches. The metal shell was then removed and a piece of the cement was cut out. The cement which underwent such great deformations did not break, and on the compressed side only rare cracks were observed. Tests proved that it still had a great resistance. This observation on concrete enclosed in a metal shell led to the belief that similar results would be obtained for hooped concrete. Numerous experiments have indeed proved that in prisms which had bent under heavy pressures the concrete did not break and it maintained its cohesion. A hooped prism of the proportion of 840 pounds of cement per cubic yard of gravel and sand and which was subjected to a pressure of 7,940 pounds per square inch of original section showed great deformation, bending in the shape of the letter S with a greatest versed sine of 0.4 inch in a length of 13 inches. The curvature was much sharper at the middle so that the least radius of curvature was about 2 feet. The "fibers" of concrete nearest to the outside did not show any transverse cracks, and hence, could not have elongated much. The flexure of the prism was, therefore, produced almost wholly by the shortening of the opposite fibers, for which computation gave the enormous figure of 17 per cent.

TABLE I.—EFFECTS OF REPEATED LONGITUDINAL COMPRESSION ON FOUR HOOPED CONCRETE PRISMS.

					First Loading and Unloading.

Note.—Pressures are given in pounds per square inch, and shortenings in decimals of an inch.

It is not certain whether the concrete could have stood this deformation if the sharpest curvature had not extended over only a short length; the obliquity and warping of the cross-sections could have had an important influence on the curvature. But the fact remains that the above prism stood considerable deformation. The hooping spirals and longitudinals were afterwards removed from this prism and the remaining concrete was coherent enough for its whole length of 4.25 feet to be handled without breaking. It was put on two blocks 3.61 feet apart and it required 55 pounds to break it by bending. One of the halves of the prism which was less bent by the warping, but which stood the same average pressure of 7,940 pounds was put on two supports 20.5 inches apart and a load of 428 pounds was required to break it.

The tensile resistance indicated by this bending test figures, by the formula $R = \frac{10\ M}{d^3}$, 250 pounds per square inch, in which M represents the bending moment and d the diameter, which the removal of the reinforcing had reduced to 4¾ inches. This tensile resistance of 205 pounds does not much differ from the initial tensile resistance of the concrete. In the compression tests without column flexure not more than 3 per cent. of shortening was observed before failure. The difference of these results is due to the considerable swelling which, in this case, is required by such shortening as would lead to failure, outside the elastic limit.

In two other prisms the compressive resistance instead of the resistance to bending was tested after the removal of the reinforcing hoops and longitudinals. The first, of the same mixture as the one above, bent under a pressure of 6,970 pounds per square inch, which caused a shortening of 0.6 per cent. The average compressive resistance of the plain concrete was 1,420 pounds and its real resistance must have much exceeded this figure, as the pressure was not well applied at the ends. A similar test was more carefully made on a prism mixed in the proportion of 630 pounds cement per cubic yard, and which stood a pressure of 10,270 pounds per square inch with a shortening of 2.4 per cent. on the average and 2.8 per cent. on the most stressed side. After removal of the reinforcing spirals, the inside cylinder, which had about 10.5 square inches section, sustained a pressure of 9,700 pounds.

From the above tests, selected as they are from many similar tests, it must be concluded that *hooped concrete sustains without failing considerable shortening and conserves a great part of its original resistance; and that with the small deformations which occur in structures, the resistance of hooped concrete can be considered to be constant from the instant when it reaches its maximum.* The analogy between this phenomenon and the behavior of concrete in tension, which the author made known some time ago, is evident.

VIII. *Elastic Behavior.—Experimental Data.*—From among a great number of results obtained from tests of prisms those given by four octagonal prisms 5.9 inches in diameter and 4.27 feet long have been chosen for the interpretation of the results. These prisms were reinforced by helicoidal spirals and longitudinal rods, as follows:

Prisms G and H, 840 pounds cement per cubic yard, spirals ¼ inch wire spaced 0.79 inch, 8 rods, 5/16 inch diameter; Prism I, concrete and spirals same as above, 20 rods, 0.276 inch diameter; Prism J, 420 pounds cement per cubic yard, spirals same as above, 8 rods, 0.276 inch diameter. Table I shows the shortening of these prisms under the given loads, the loading being repeated as indicated.

In all of these specimens the spirals had the same dimensions, and in the first three the concrete was of the same mixture. Similar results might have been expected of them, but the facts proved otherwise. While for the first prism the pressures below 2,845 pounds per square inch gave a co-efficient of elasticity of 7,111,000 pounds, the second of identical composition gave only 2,845,000. This great difference was due to the quantity of water used for the mixing of the concrete; it was correct for the first and excessive for the second. The first lesson taught by these experiments is the great irregularity of concrete as usually fabricated, and the doubtful value of results based on the coefficient of elasticity.

If the general behavior of the deformation curves of the prisms be studied, it is noticed that they show an important change of inclination after a certain pressure has been exceeded, the same as is shown for ductile metals.

This point may be called the elastic limit, but without attributing to it the sense usually given to this limit. An elastic limit, in the proper meaning of the words, does not exist for concrete. Prisms of the same concrete do not show so much irregularity in their elastic limit as in their coefficient. The first three specimens thus had an elastic limit varying between 4,830 and 5,400 pounds per square inch. The elastic limit, moreover, varies with the proportion of cement, while the coefficient of elasticity, on the contrary, is little influenced by it. For prism J it reached only 2,845 pounds per square inch. These results are in accord with what is known of concrete that is not reinforced.

The observation of the deformations during the loading and unloading of the specimens has given results of great practical interest. The first thing shown which could have been anticipated, was a permanent shortening which increases if the same load is repeated, but more and more slowly and tending rapidly towards a final limit. A reduction of the total deformations is thus obtained and with it an appreciable increase in the coefficient of elasticity for the succeeding loadings and unloadings of the specimens. The second result, which is more important, could not have been foreseen. It is the form of the deformation curves and especially the direction of their curvature, which is concave to the pressure axis, while during the first application of load it curves in the inverse sense. It follows that *the coefficient of elasticity which is represented by the inclination of the tangent to the curve of deformation increases with the pressure in the unloading and reloading instead of decreasing with increasing pressure as under the first application of load.* The importance of this fact will be more fully discussed under "column flexture," but it is well to indicate here its bearing.

Evidently flexure is to be feared in a column generating cylinder was 3.76 inches. In addition the prism was reinforced by 8 longitudinal wires of the same size and material. The length of the prism was 51.18 inches.

Column flexure prevented the measurement of the shortening under the pressure of 10,290 pounds per square inch. Figure 1 shows the plotted results of these and numerous other experiments not given in table No. II. The concrete surrounding the spirals was removed to a cylinder of 3.37 inches, which just passed through the middle of the re-enforcing wires. The effect of the external layer of concrete was thus eliminated because of the difficulty in determining its action precisely. The pressure was successively raised in four applications to 2,360, 5,530, 7,910 and 10,290 pounds. After each of the highest pressures, the load was gradually decreased and then applied again and the shortening measured carefully under each pressure.

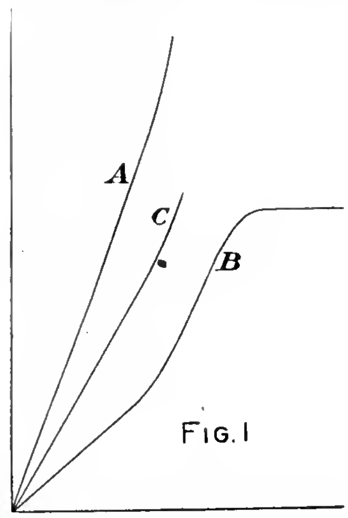

FIG. I

The coefficients of elasticity corresponding to the different pressures are proportional to the tangents of the deformation curves. They are given below as determined under the first reloading and under the following unloadings and reloadings. For simplicity's sake only the average of the two last operations is given:

TABLE II.—EFFECTS OF REPEATED LONGITUDINAL COMPRESSION ON A HOOPED CONCRETE PRISM.

First Loading and Unloading.

Note.—Pressures in pounds per square inch; shortenings in decimals of an inch.

under high pressures and it is, therefore, unfortunate that the coefficient of elasticity, which is directly proportional to the column resistance, decreases with the increase of pressure. Such is the case under the first application of the load for hooped or otherwise reinforced concrete and also for structural iron and steel. On the other hand, it must be considered especially fortunate that hooped concrete which has been subjected to a first load has a coefficient of elasticity which is the greater the higher the pressure becomes, provided it does not exceed the first load. This fact has, to the author's knowledge, never before been observed on other materials. To better discuss this point the results of a very exact experiment, made at the laboratory of the Ponts et Chaussées, are given in table Number II, herewith. The prism tested had an octagonal section of 4.3 inches diameter and was made of concrete of the proportion of 1,000 pounds of cement to 32 cubic feet of gravel 0.2 to 1 inch in diameter and 10.7 cubic feet of sand passed through a screen of 0.2-inch holes. The helicoidal spirals were of iron wire 0.17 inch in diameter and 0.82 inch centers to centers. The average diameter of their

Pressures in pounds per square inch	853	1,990	4,270	6,830
Coefficient of elasticity under first loading	2,180,000	853,000	384,000	284,000
Coefficient of elasticity under unloadings and reloadings	1,990,000	4,910,000	2,420,000	3,275,000

After the considerable pressure of 10,290 pounds per square inch had been applied it was taken off and it was found that the prism had gone back to a coefficient of elasticity as high as after the application of the lightest pressures. The experiments given in the first table lead to the same conclusions. Besides, the comparison of the relative values of the different prisms shows that the first application of load improves the concrete in the same degree as it had initially been deficient. It is natural, indeed, that a strong pressure should diminish the final deformability by bringing the particles nearer together, and that this effect should be greater the less the concrete has been tamped and the farther apart the particles were before.

Continuing the discussion of the results of the above experiments on the effect of the first loading it may be stated:

The application of a first pressure on a hooped prism, no matter how high the pressure may be, has the effect of raising its elastic limit up to that pressure. The coefficient of elasticity which is developed by the hooped concrete under all the variations of the pressures between the lowest and the previously applied load is higher than the highest coefficient of elasticity which the prism had before the test load and which held out for a low pressure only. The increase in the coefficient of elasticity of the concrete after the test load, as compared to the coefficient before is so much more, the poorer the concrete was made and the lower quality it had.

These properties are similar to those of the ferric metals whose elastic limit also increases to the pressure once applied; but they differ by the curvature of the deformation curve, which shows increasing values of the coefficient of elasticity of hooped concrete at pressures below the test load. Hooped concrete does not show, in this regard, any similarity to reinforced concrete in tension, whose coefficient of elasticity decreases considerably after appreciable deformations, and the more so the greater the deformations have been.

It will be seen below that it appears possible to utilize the above properties of hooped concrete. This has never been attempted for the metals, and it is easily seen why. It is almost impossible to subject the individual members of a metal structure to a preliminary pressure. They do not, generally, offer convenient bearing places and it is to be feared that the riveted connections would be distorted under high stresses. But it seems, on the contrary, possible to submit to high pressures ring stones of hooped concrete with plane faces. It is not certain that in some cases it would not be advantageous to obtain hooped prisms whose elastic limit will reach up from 7,000 to 10,000 pounds per square inch and whose stresses may run up higher still. To obtain such results the prisms will have to be subjected to pressures which will crush the concrete layer outside of the spirals. After the test a concrete coating will be put on in which asbestos may be substituted for the sand, which will make it much more ductile. It is already used in the making of roofing material of surprising solidity.

The Water Supply of Paris is to be increased so as to give a total of 237,760,000 gallons daily instead of 73,970,000 gallons as at present, if the plan now proposed by the engineers is carried out. The estimated population for 1903 is 4,000,000, and a per capita consumption of 59.4 gallons is taken as a fair average. It is proposed to increase the supply by collecting the water in the Val d'Orleans, where there is a subterranean lake fed by the River Loire. This will require an aqueduct 62 miles long, and the estimated cost of the project is $25,090,000. It is necessary for the Paris Municipal Council to give its sanction to the scheme.

The Safety-Appliance Law of 1893, designed to protect railway employes engaged in coupling cars, is performing its work efficiently, according to the last report of the Interstate Commerce Commission. The number of persons killed and injured in coupling and uncoupling cars during the year ending June 30, 1902—the first entire year reported since the law went into full effect—shows a diminution as compared with 1893, of 68 per cent. in the number killed and 81 per cent. in the number injured. In 1893 the number of casualties from this cause was 11,710, of which 433 were killed and 11,277 were injured. In 1902 the total number was 2,256, of which 143 were killed and 2,113 injured. This shows a reduction of 9,454; and it it is to be borne in mind that the number of men engaged in this work is much greater now than it was in 1893.

Boston's Projected Underground Railways.

In the preceding issue was a brief mention of the acceptance, by the citizens of Boston, of an act providing for additional underground railways. In 1895-98, after prolonged and thorough study of the rapid transit problem, Boston built a system of subways extending in a general north and south direction through the congested shopping district of the older part of the city, with a branch subway toward the southwest to accommodate the large number of cars carrying passengers to the western residential districts and suburbs. In 1896 the West End Street Railway Company leased these subways and, in 1898 the Boston Elevated Railway Company (lessee of the West End Street Railway Company) built a system of elevated railways extending northerly through Charlestown and southwesterly into Roxbury, with a line connecting the North and South railroad terminal stations.

The subways were intended originally for surface cars only, but were adapted for elevated trains and are being used by both elevated and surface cars, on independent tracks. In 1900 the East Boston tunnel was begun to supplant the ferries across the harbor and connect the East Boston car system with the subways in Boston. This tunnel is still under construction. All the works mentioned above have been described in The Engineering Record from time to time.

While much has been gained by these improved means of transportation, certain car lines and some streets have remained congested and even the newer facilities are already crowded in the busy hours. Chapter 534 of the Acts of the Legislature of 1902, "To provide for the construction of additional tunnels and subways in the city of Boston" was accepted, on referendum, at the city election, December 9, by a vote of 41,970 to 15,333. The act empowers the Boston Transit Commission, which has had charge of the construction of the earlier subways and the East Boston tunnel, to build a system of tunnels and subways so designed as to be adapted for the accommodation of two tracks especially for use by elevated cars or trains and two tracks for surface cars, with the necessary approaches, stations and other appurtenances, including connections with the East Boston tunnel and the existing subway. The new tunnel and the new subway may be built entirely separate or may be connected, as may be decided by the commission to be most economical and convenient for traffic. The exact locations have not been determined but are limited to a territory averaging about 1,200 feet in width easterly from the existing subway, excepting that north of Scollay Square the zone of location extends to the westward of the existing subway a similar distance, as well as to the eastward.

The act requires that the construction of the tunnel shall be begun immediately and of the subway at such time after the expiration of one year from the completion of the tunnel as the Commission and the Boston Elevated Railway Company may agree upon, but it is intended to push the construction of the subway also.

Preliminary examinations, in the way of borings and surveys and tests of building foundations along probable routes, have already been instituted. It is hoped that these examinations and the preparation of plans and specifications may be so expedited as to make possible the letting of contracts for construction within six months. The act, approved June 27. 1902, required that a contract for the use of the tunnel and subway should be made by and between the Boston Transit Commission and the Boston Elevated Railway Company before a reference of the act to the voters at the succeeding municipal election. Such a contract was signed September 25, and many of its items are so interesting that they are abstracted below.

The term is twenty-five years from the beginning of the use of the tunnel, and the annual rental is to be 4½ per cent. of the net cost of the tunnel and subway respectively, including all expenditures incurred in acquisition and construction—damages, expenses, salaries of the commission, and interest at 3¼ per cent. per annum on the debt incurred in construction prior to the beginning of use. Such net cost shall also include amounts expended for preliminary investigations and for alterations in the existing subway and approaches thereto necessary to readapt it to the use of surface cars. Deductions shall be made from the cost for the proceeds from sales of property and for a fair valuation of lands and structures no longed needed for the purposes of transportation.

If at any time during the continuance of the term of this contract the company shall be deprived in whole or in part of the use of the premises by any cause growing out of the act of God, of public enemies, of mobs or of riots; or growing out of works or excavations carried on or permitted by the city or other public authority; or growing out of explosions or the bursting of pipes outside the premises, the falling or settling of buildings, the filling or caving in or other physical obstruction of the premises or any part thereof not due to any act of the company, or its agents, servants or licensees, in the use of the premises, or to any negligence on its or their part, or to any failure of the company to maintain the premises in good order and condition as provided; or growing out of the location, maintenance or use of the wires or other apparatus which the city is authorized to maintain in the premises; then the rental or a just and reasonable part thereof, as agreed upon by the Mayor of the city and the company or in case of difference as determined by arbitration, shall be suspended or abated during such deprivation.

All the tracks and equipment provided by the company shall remain its property so long as it continues to occupy or use the tunnel under the provisions of the contract and upon the termination of such use the city agrees to take and pay for all such property at its then fair value. The company is to maintain the premises in good order and shall be entitled at all reasonable times to a permit to open the streets and other public grounds for the purpose of repairs, which shall be at the expense of the company except repairs made necessary by the uncontrollable causes mentioned above. The city shall not be responsible to the company for damages of any description resulting from any defects in the premises, whether structural or arising out of want of repair or from any cause after use by the company has begun.

The company shall keep the premises thoroughly clean and free from unnecessary dampness, and the approaches to stations clean and free from ice and snow. When the premises are in use it shall suitably light the same in all parts, and by means of artificial ventilation shall keep the air adequately pure for health and comfort. The governor of the commonwealth, the Mayor and engineer of the city, and the members of the Board of Railroad Commissioners, and of the commission, and their respective engineers shall at all times have free entry to the premises for the purpose of inspecting the same.

The company may permit persons or corporations not engaged in the railway business to use and maintain wires, conduits and similar structures to such extent as may be practicable without interfering with the safe and convenient operation of the railway. But the privilege shall not extend to gas or water pipes. The city may place in the premises wires and apparatus for its police and fire alarm service, the location and construction, maintenance and repair to be subject to such reasonable direction and regulations as the company may impose.

In the event of the failure of the company or its assigns to pay the rental for three months after such rental shall have become due, or in the event of a failure to maintain and operate a railway within the premises, and if such failure shall have continued for three months, then in either of said events the city upon three months' notice, such default still continuing, shall have the right to terminate this contract and to re-enter upon and repossess itself of the premises, unless such failure to maintain and operate grows out of the previously mentioned uncontrollable causes.

In case the right of re-entry and repossession above given shall be exercised, all the tracks, wires, apparatus, equipment and other property in the nature of fixtures of the company or its assigns within the premises may be taken by the city and be paid for by it at a valuation to be determined as provided for the occasion when the same are to be surrendered by the company at the expiration of the term of the contract. The company shall have no right at any time to remove from the premises any tracks, wires, apparatus, equipment or other property necessary to the use and maintenance of the premises and the operation of a railway therein, except for the purpose of repairs or renewal or for the substitution of equivalent structures, property, apparatus or equipment.

The act requires that the commission shall not begin construction until it has filed in the office of the city engineer a plan showing the location of that part of the work which it is about to construct. All work under or near public streets shall be conducted, so far as practicable, so as to leave the streets or a reasonable part of them open for traffc between the hours of 8 A. M. and 6 P. M. of each secular day except public holidays. Recollection of the disastrous explosion which occurred in connection with the construction of the existing subway is shown in the provision that any gas company can shut off the gas from any pipes affected by the work when necessary to avoid danger.

The Name of the American Society of Civil Engineers is being dishonestly used by a certain party, and so the secretary has sent to members the following letter of warning:

"It has come to the attention of the secretary that members in various parts of the country have been approached by persons claiming connection with the society, and, on the basis of such claim, securing financial aid. A recent case is that of a young man who by impersonating F. F. Hall, Jun., Am. Soc. C. E., at Duluth, Minn., has succeeded in swindling several of our members there. Members are warned to look out for this man. It is needless to say that such use of the name of the society should be promptly punished, but this is difficult and can only be accomplished by the individual who is victimized. The object of this circular is to suggest to members that the mere statement of connection with this society is not proof of such connection, and that in all cases the production of some identification by a self-introduced claimant should be insisted upon, both for the protection of the individual and the good name of the society."

Property Returns on Public Works.

By A. F. Bridgman, Auditor, Metropolitan Water and Sewerage Board, Boston.

The taking account of stock or annual inventory of the merchant or manufacturer is so manifestly a part of his business system, and the care and thoroughness with which it is done is so clearly an important element in arriving at his business standing, that no one doubts its necessity. On public works, however, the accounting for property used in the construction or operation of the works is often thought to be of little importance, and in fact when looked at from the point of view of the merchant or manufacturer this may be true; but when it is remembered that a public work by its very nature requires regular and systematic statements regarding the means used for its prosecution, whether of men, money or appliance, the account of stock is seen to have its value.

When office furniture and fittings, engineering instruments, machinery, tools, appliances and materials for construction are purchased and delivered to a department for use in the work of construction or operation, there should be a thorough and systematic accounting for the same at regular intervals to some person who has entire knowledge of all supplies purchased and disbursed; and in general it may be said, the greater the work, the more important are careful returns.

A brief outline of the methods adopted by the federal and State governments, and various commissions in charge of public works, will show how this matter is regarded. The United States government requires a property return from its disbursing officers at the close of each three months, and the details of these quarterly returns are so elaborate as to make the return usually made on engineering works seem like play. The articles received and disbursed during each quarter are not only given in much detail, but the former are accompanied by the vouchers showing the source from which the property came and the latter by the certificate of the person under whose direction the articles were used.

In some of the Massachusetts State departments a return is made semi-annually, showing property on hand at the beginning, the amount received during the six months, the amount used up and the balance remaining on hand. Of the commissions carrying on important public works in Boston and in the metropolitan district, the Metropolitan Park Commission has a general return of property annually. The superintendents of the different reservations make up their returns and send the same in book form to the secretary of the Board, who compares and compiles the entire account.

The act under which the Metropolitan water works are being constructed requires that a full property account be kept and an abstract of the same published in the annual report of the Metropolitan Water and Sewerage Board, which carries on that work. A property return is, therefore, compiled showing all property on hand at the close of the fiscal year and for articles not classed as perishable the amount on hand at the beginning of the year as well as the amount received and disposed of during the year.

Members of the engineering profession do not as a rule look with unalloyed pleasure upon this work of recording and reporting the receipts and disbursements of property placed in their charge, and usually carry it to completion only under the stimulus of a forced draught. When a dam is to be designed or a road built the work is entered upon with the same zest that the well-known war horse is said to show when entering a battle, but when an inventory is to be taken and a return of the property compiled the task is approached with anticipations similar to those of a boy approaching a school house. And the reason is that a great responsibility for the good character of the strictly engineering work under his care has such a prominent place in his mind, and rightly, too, that the care and accounting for the means used in carrying on the work seems dull business. In other words it seems a kind of a by-product of engineering work and an unprofitable one at that.

Now, how can a full and regular accounting for engineering property be obtained without making life miserable at stated times for the members of the engineering profession? First, by remembering that the accounting of property is like the accounting for money, and should be expected and planned for in a similar way, for unless one is willing to account for things submitted to his care, he should not accept the trust. Second, by entering property received in a book, in a similar manner to which cash received is entered, and, so far as is possible, stating what has become of property not on hand when each periodical account is rendered. Third, by using blanks which will cover the range of articles to be used, as far as may be foreseen, with plenty of room for additional items, a grouping of different classes of property under separate headings, so that any item may be easily placed, and entering items in each class in alphabetical order. When these things are done, the principal aids in the work will be at command.

For most engineering work, so called, the following general classification will be found to locate property in a natural way:

Office furniture, fixtures and supplies.

Engineering and draughting instruments and supplies.

Tools, machinery and appliances for construction.

Horses, vehicles and stable supplies.

Stock, i. e., material to be used in and in connection with the structures themselves.

Under each general heading place the items, grouping small classes of articles where practicable and avoiding too fine a separation of different kinds of the same article. The accompanying example will suggest a form of blank:

PROPERTY RETURN.

Tools, Machinery and Appliances.

	On hand last account.	Received since.	Total to account for.	Disposed of.	Now on hand.	Remarks.
Axes, all kinds	12	0	12	2	10	....
Barrows, wood	40	20	60	14	46	Worn out
Barrows, iron	10	0	10	1	9	Broken
Bars	34	10	44	36	8	4 lost in trench, 2 stolen
Blasting supplies—						
Battery	1	0	1	0	1	....
Black powder (lbs.)	200	0	200	50	150	Used at dam
Dynamite (lbs.)	40	30	70	60	10	Used at dam
Fuse (ft.)	..	200	200	250	50	Used at dam
Leading wire (ft.)	..	500	500	...	500	....
Boilers—						
Horizontal, 10 H.-P.; upright, 25 H.-P.	2	0	2	1	1	Transferred to Road Dept.

In the general office, where bills are filed after payment, should be kept a book called the Property Book and arranged as shown by the accompanying example:

PROPERTY BOOK.

Date of bill.	Number of bill.	Name of article. Axes.	Sent to— Sec. 1.	Sec. 2.	Pump. Sta.
Jan. 31	2240	Wood chopping	12	..	..
Feb. 4	2422	Hand	..	6	..
		Broad	..	..	3
Mar. 1	2690	Wood chopping	12	..	..

On most large works all bills after payment and before being turned over to the bookkeeper receive a consecutive number, and are thenceforward for convenience referred to by that number alone. If this method is not used the firm name may be entered instead in the second column. Each article has a half-page, page or two pages, as is judged sufficient, and is indexed the same as in a letter book.

When the return is made by the different departments to the general office, the second column of the first table ("received since last account") is checked with the charges in the property book, and by this means it may be seen whether the property sent out has been accounted for, and in case of variance the difference can usually be adjusted by correspondence. Property received or disposed of by transfer from one department to another should be so noted in the column of remarks. A comparison of the two reports will then show a proper accounting. Property condemned as unfit for use should, to avoid uncertainty as to reporting it in future accounts, be marked as such, or be permanently disposed of.

The cost of making a complete report of miscellaneous property as outlined above will be found to be about one per cent. of the value of the property reported.

Civil Service Examinations for engineers in the New York State department will be held January 24, 1903, for the following positions: Assistant civil engineer, $5 per day; chainman, $2.50 and $3 per day; leveler, $4.50 per day; rodman, $3.50 per day; and structural engineer in the State architect's office, $2,000 per year. Persons desiring to take these examinations should file applications on regular blanks before noon of January 19. For places of examination and particulars, address Chief Examiner, State Civil Service Commission, Albany.

The Purification of Polluted Sea Water by aquatic plants was brought to the attention of the British Association for the Advancement of Science recently by Professor E. A. Letts and Mr. J. S. Totton, a summary of the paper appearing in "Engineering." It was stated that the so-called sea lettuce (ulva latissima) grows luxuriously in the shallow parts of Belfast Harbor, where the water is almost constantly polluted by sewage, and often drifts ashore in thick layers, where it rots during the summer and autumn and becomes a serious nuisance. The decomposition is so like animal putrefaction that investigations were begun. It was found that the dry weed contains as much as 6.2 per cent. of nitrogen, corresponding to 38 per cent. of albuminoids, which is very high for a plant. Bringing the lettuce, before and after its fronds had developed, in contact with polluted sea water, it was observed that the nitrogenous matter—ammonia and nitrates contained in sewage—was absorbed from the sea water to which it was added in five hours. The sea lettuce would thus appear to be capable of acting as a scavenger. There are other sea-weeds and fresh-water plants, including an alga, about whose name Professor Letts was not certain, capable of absorbing ammonia, and it was hence suggested that these weeds might be utilized as purifying agents, either alone or for a final treatment of the effluent from some ordinary sewage process before that effluent is allowed to pass into the rivers or estuaries.

Superheated Steam.

Abstract of a paper read by Mr. Ernest Foster before the Engine Builders' Association of the United States.

In considering the advantages and disadvantages of superheating with regard to engine work, let us recognize the four distinct conditions under which steam is used: Saturated, superdried, moderately superheated, highly superheated. Saturated steam may be taken as commercially dry steam or such as is delivered by a good boiler under ordinary conditions. By superdried steam, we mean steam which is not only thoroughly dried in the superheater, but which is raised in temperature thirty or forty degrees above the saturation point, or just enough to insure its arriving at the engine in a perfectly dry state. To such an arrangement there could possibly be no objection as the steam is delivered at the engine free from moisture and without the use of a separator or means of trapping out condensation.

By a moderate superheat, we mean from 100 to 150 degrees at the boiler, which should give in the neighborhood of 100 degrees at the engine and be sufficient, with proper protection, to carry the steam nearly, if not quite, through one cylinder without condensation. If the engine is compound, the steam, having lost its superheat at the terminal point of the high pressure cylinder, is re-superheated about 100 degrees in a reheater between the high and low pressure cylinders and again loses its superheat while expanding into the low pressure cylinder, arriving at the point of exhaust with the temperature of saturation. This arrangement may be considered at the present time as the best which can be proposed. The amount of superheat is so moderate as not to require anything more than good construction for modern high steam pressures.

Highly superheated steam must be treated with more consideration. Engines which will stand a temperature of 500 degrees F. are not necessarily fitted to handle steam at 750 degrees, but these temperatures may be, and have been repeatedly, used successfully. As shown by many published reports of tests at various points of superheat, an increase in temperature is accompanied by a decrease in steam consumption, hence it is worth while pursuing this line. To employ these high temperatures, it is at present considered important to use poppet valves on the high pressure cylinders at least, as it is here that the full effect of the superheat is felt, and this type of valve is easier to lubricate and does not become distorted with heat. We believe, however, that a Corliss valve may be so proportioned as to operate successfully under even these conditions.

One of the well known methods of utilizing high superheat is that known as the Schmidt system. This consists in passing a portion of the highly superheated steam directly from the boiler through the reheating tubes of a receiver, between the high and low pressure cylinder of a compound engine, and then letting this steam mix with that which enters the high pressure cylinder direct from the boiler. The high pressure exhaust is thus superheated on its way to the low pressure cylinder while the temperature of the steam admitted to the high pressure cylinder is modified by its admixture with steam which has already been through the reheater coils and incidentally a receiver drain is unnecessary. Automatic regulation of the superheat to a desirable point in each cylinder, under a varying load, is claimed for this system. Ordinarily an increase of load beyond normal necessitating a late point of cut-off in the high pressure cylinder will give an excess of superheat in this cylinder while the reheater will not be sufficiently active to superheat this steam on its way to the second cylinder. With the Schmidt system, however, the effect is reversed by causing a greater amount of steam to pass through the receiver coils where it gives up its superheat to the low pressure cylinder during periods of heavy draught and the high pressure cylinder is thus protected from excessive heat. The contrary effect in both instances may be followed through in case of an engine running under a light load.

In the present state of the art it would seem that the condition most attractive to American engine builders would be one of moderate superheat. We thus confine ourselves to a conservative policy and avoid the necessity for making any special provision for extremely high temperature. We use lubricants, and gaskets and packing which may be obtained in the open market at a reasonable cost, while at the same time we avail ourselves of such positive and direct benefits of superheating as: Dry steam in the pipes and throughout the engine, elimination of separator, low steam consumption per unit of work done, smaller steam pipes and ports, simplified system of steam jackets, greater amount of work done per boiler capacity, and efficiency at light loads. These are all practical and common sense improvements, and are of such proportion as to fix our attention.

The absence of water with the steam need not be dwelt upon. Every practical man will admit that this is of great value. It is further noticeable that a steam pipe system which will show leakage at the joints with saturated steam will become perfectly tight under superheated steam. The point of maximum economy, while using superheated steam, has by no means been reached. The amount of data available is not in proportion to the extent of the practice.

In order to make a comparison between superheated and saturated steam consumption of an engine it is, of course, only fair to place both on a heat unit basis, thus eliminating entirely the question of the cost of the superheat. Assuming a compound engine of about 1,000 horse-power and running with 150 pounds initial and 26 inches vacuum, we would consider 12½ pounds of fuel per indicated horsepower per hour a very good result. We have well authenticated reports of a similar engine, supplied with steam with a temperature of 720 degrees Fahrenheit at the boiler, consuming less than 9 pounds of steam per indicated horsepower, or a gain of 39 per cent. in economy with an expenditure of but 16 per cent. more heat units in the boiler.

The reduction in the size of steam pipes and ports rendered possible by using superheated steam is due to the diminished density of an equal volume as compared with saturated steam as well as from the absence of entrained water. The velocity of superheated steam in pipes should be kept up in the neighborhood of 6,000 feet per minute. As a rough approximation it may be said that superheating will make a difference of 20 per cent. in the size of the steam pipe.

The question of steam jackets on a cylinder, which has occupied so much profound attention in recent years, is quickly solved by the aid of superheated steam, and we see at once the benefit of the jacket disappear as a steam economizer. There seems to be no excuse for retaining them on the low pressure cylinder, and indeed we have proved by trial that on this cylinder a steam jacket is positively wasteful. We do not think it clearly proved, however, that they may not still be useful when applied to the high pressure cylinder even if only for the sake of warming a large engine up preliminary to starting.

The effect of getting more work out of a certain volume of steam is naturally felt in the handling of the boilers and in a reduction in the number of fires necessary to do a given amount of work. Unexpected results have been frequently obtained by the addition of a superheater to a boiler and a higher evaporative efficiency with the superheater in commission has been shown. This is doubtless due to the increase of the heating surface and the lowering of the temperature of the flue gases. In such cases the saving by superheating is felt in the coal pile to the same extent as in the steam consumption.

On the acceptance test of some vertical compound engines of 1,200 and 2,400 horse-power on electric light service in Boston the maintaining of efficiency under light loads was well demonstrated. The feed water per indicated horse power per hour was 12.54, 12.51 and 12.00 pounds at full load, three-quarter load, and one-half load respectively, while the amount of superheat was 80 degrees, 64 degrees and 48 degrees at the high pressure admission and 60 degrees, 67 degrees and 84 degress at the low pressure admission. The engine had reheaters and steam jackets on both cylinders, and it is not unlikely that still better results would have been obtained had the low pressure jackets been omitted. It must not be considered necessary to make any very extensive preparations for the use of superheated steam, it may almost be said that the requirements are merely in the line of good practice, and, as such, should be inaugurated in any event.

It is important to have the joints of the steam pipes firmly made and well bolted; corrugated brass gaskets are usually found very satisfactory with superheated steam. Provision must, of course, be made for the expansion and contraction of the steam lines to a somewhat greater extent than ordinarily, and the steam pipes as well as the flanged unions should be covered with a good non-conducting material in a thick layer. It is important to have the flanged unions covered as well as the pipe. With proper precautions of this sort and with a velocity of steam in the pipes of from 4,000 to 6,000 feet per minute, the drop in temperature per foot of run may easily be kept down to 1 degree in 6 or 7 feet of length.

Metal of low melting point must, of course, be avoided in the construction of the engine, especially about the valves and piston rods. The stuffing box bushings must be made of metal which will not run under the temperatures likely to be encountered. The metal should be uniformly distributed in designing the valves and cylinders to get the best results with superheated steam, as in this way a uniform expansion by heat is provided for. The boiler and the cylinders are preferably made without projections or ribs. The poppet valve has the advantage in form, but the Corliss valve is also made in such a manner as to expand and contract without warping, and the large number of Corliss engines using superheated steam is a strong evidence of their adaptability.

The lubrication of the cylinders is apt to cause one who has not had experience with superheated steam a great deal of unnecessary anxiety, but really this problem is very simple. It must be borne in mind that the temperature inside of the cylinder is never very high, even when the superheat at the entrance is very considerable, and if the cylinder is lubricated directly without mixing the oil with the steam at the entrance point there can possibly be no difficulty. With any reasonably good grade mineral oil, however, it cannot be claimed that any difficulty has been experienced with the lubrication of the parts, even when applied in the ordinary way.

The effect of superheated steam in the indicator diagrams is worthy of notice. Steam being used as a perfect gas, the diagram approaches more nearly the theoretical, and, as there can be no re-evaporation in the cylinder the tendency of the pressure to rise during the stroke is absent and the amount of work done in the low pressure cylinder is brought down to the proper point.

In designing an engine to be run with superheated steam it is well to bear this point in mind as there is danger of applying the usual constants in the selection of the size of the cylinder for the reason that the horse power of the steam end used with superheated steam will be nearer the theoretical.

Superheated steam is destined to play an important part in the adoption of the steam turbine. Already a number of tests have been published which show a considerable decrease in the steam consumption with the amount of superheating, and it is not difficult to understand that a machine of this type would be greatly benefited even by the elimination of moisture and dense vapor from the propelling medium. Other uses for superheated steam, such as for dryers, chemical processes and boiling or distilling apparatus, will not be touched upon in this paper, and it may be said in conclusion that the author believes that the time has arrived when steam will not be used to any great extent in any branch of industry without being superheated.

A Turbine Water Meter.

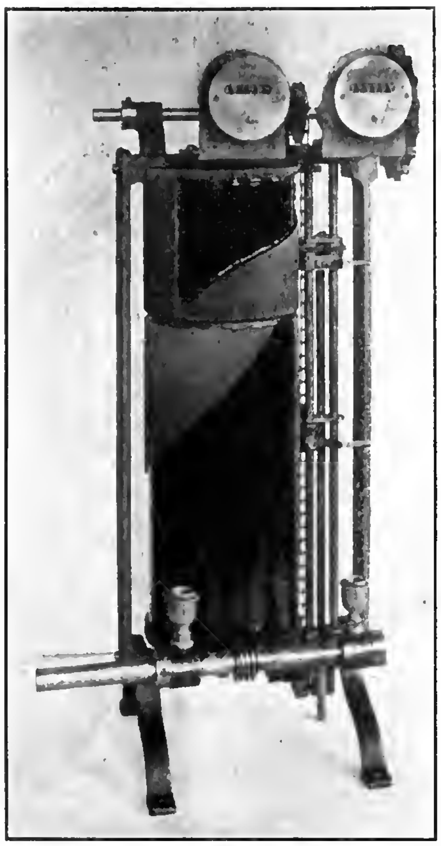
The accompanying illustration is a reproduction from a photograph of a water-wheel flow recorder designed by Mr. George I. Rockwood, of Worcester, Mass., and Mr. C. M. Allen, assistant professor in experimental engineering at the Worcester Polytechnic Institute. It is an ingenious device for recording the discharge of a turbine, taking into account the effect of the degree of gate opening and the effect of change of head. It is intended to secure a continuous reading of the amount of water diverted for power purposes and also allows simultaneous direct readings of both head and gate opening to be made in a convenient way, displacing the common practice of taking two or three observations daily of these conditions, to estimate the amount of power developed by the turbine. As a water meter and an indicator of the operating head, the apparatus is held as more reliable in the way of evidence in water power litigations than the comparatively infrequent records of the ordinary method of securing these data.

The essential part of the machine consists of two cylindrical drums, each having a toothed surface, covering a portion of the cylinders. The lower drum is driven by worm wheel gearing from the turbine, and always bears a definite speed relation to the turbine. By means of its toothed surface it drives a small gear wheel mounted on a shaft on the top of which is another pinion. This wheel drives the upper cylinder and this in turn, by means of its toothed surface, drives a third pinion, mounted loosely on the shaft between the other two pinions. The third pinion mates with a fourth pinion of the same size, which is keyed to a second shaft and actuates by means of bevel gearing at the top a clock-work registering device.

The lower cylinder is designed to give the reading as affected by a change of gate opening. The pinion corresponding to this cylinder is mounted on a feather key and is raised or lowered along the shaft by means of a chain, shown in the photograph, the chain being actuated as the gate is opened or closed by means of another chain, not shown, engaging the sprocket at the right of the right-hand dial.

For any given gate opening the pinion assumes a particular position and is revolved by the gate cylinder, as the lower cylinder may be called. The number of turns it makes depends on the number of teeth on the gate cylinder, corresponding to that position. The toothed surface is thus bounded by a curved line, so that for any gate opening the pinion will be rotated to the proper extent, that is, by the proper number of teeth proportional to the turbine discharge; and this curve is obtained from a previous test of the turbine under a given constant head and varying amounts of gate opening, checked against a weir.

In a similar way the head or upper cylinder has a toothed surface which varies the number of revolutions through which its pinion is turned proportionally to the amount of water the turbine discharges at a particular head; and the pinion moves vertically as the head is changed. For a maximum gate opening and a maximum head, the gate pinion will be at the top of the gate cylinder and be revolved the



Water Wheel Flow Recorder.

greatest number of times per revolution of the gate cylinder; and the head cylinder, which will move at its highest speed, being driven through the gate pinion, will turn the head pinion, which will be located opposite the bottom of the head cylinder, at its highest number of turns and thus give to the dial its maximum reading per revolution of the gate cylinder.

For a maximum gate opening and a varying head, the upper pinion will rise and reduce the maximum reading by the required amount. In short, the lower cylinder will give the reading at maximum head and any given gate opening and the upper cylinder will reduce that reading if the head is less than the maximum.

The apparatus for measuring the head acting on the wheel, takes into account the level of the tail water. It consists of a leather diaphragm submerged in the tail race. One side of the diaphragm is exposed to the tail water and the other forms one end of a water-tight chamber, which is connected to an oil reservoir in the wheel casing. The chamber and pipe connections are kept full of oil to prevent freezing. The pressure on the diaphragm is balanced by a heavy spring. The motion of the diaphragm caused by a change in head is transmitted through a rod and multiplying lever to the carriage which holds the pair of gears opposite the head cylinder.

Such a meter has been installed by the Worcester Polytechnic Institute for recording the flow of water at the hydraulic testing laboratory, at Holden, Mass., in connection with an 18-inch Hercules turbine operating under a head of 30 feet. The cylinders of the meter are 5¾ inches in diameter, and the two together, 16⅝ inches long. There are 276 teeth on the full circumference of each cylinder, and 48 on each of the small gears. The two pointers show directly the location of the gate and head pinions, traveling against scales for that purpose. The left-hand dial gives the revolutions of the turbine by connection with the gate cylinder. Other installations of these meters have been made, the first one being at the woolen mills at Gilbertville, Mass., nearly two years ago.

The Two Public Baths of Yonkers, N. Y., furnished 23,182 and 11,043 baths during the year ending December 1, 1902, according to the annual message of Mayor M. J. Walsh. Of the total number, 8,438 were free, the remainder having been paid for at the rate of 5 cents each.

The Pumpage of Water for the city of Chicago during 1901 was at the average daily rate of 343,282,508 gallons, an increase of 20,276,316 gallons over that of the previous year. The amount of coal consumed, however, was 2,294 tons less than during the previous year, according to the annual report of Mr. F. W. Blocki, Commissioner of Public Works. The daily pumpage per capita was 164.8 gallons.

The Roadways of Birmingham, England, were recently described in the presidential address of Mr. John Price to the Association of Birmingham Students of the Institution of Civil Engineers, from which the following notes have been taken. It is found that when a macadamized road requires an entirely new surface once in three years, granite block paving becomes more economical; and again, when this period is reduced below two years, then wood, for the same reason, can be laid down with advantage. When the grade of the road is less than 1 in 25 macadam is considered a suitable material. Above that, granite paving can be used; and it is not considered wise to use soft wood where the grade is steeper than 1 in 40, or hard wood with a grade steeper than 1 in 50. Various kinds of wood blocks have been used in Birmingham, with very satisfactory results. The pavement is laid on a 5-inch cement concrete foundation, carefully finished off to a smooth surface with 1 inch of 1:2 Portland cement mortar. The blocks, varying from 4 to 6 inches in depth, are laid close and run solid with hot asphalt. Along the curb on both sides an expansion joint of clay and sand is left, from 1 to 2 inches width, the greater width being used with blocks of soft wood. It is necessary to keep hard wood block paving watered in the summer time or the blocks are likely to become loose. The crowning of the roadways in Birmingham is determined according to a series of constants, and depends on the different classes of paving materials used. For macadam, the height of crown above the gutter is 1/24 the half width of the roadway, for granite it is 1/36, for soft wood 1/40, and for hard wood 1/45. Having determined the height of the center above the gutter, three equidistant intermediate points are found by multiplying this height by .87, .65, and .35.

The Stability of Effluents of Sewage Filters of Coarse Materials.

Slightly condensed from a paper by H. W. Clark, Chemist, in the 1901 Report of the State Board of Health of Massachusetts. Tables omitted.

All organic matter is presumably subject to change by bacteria. It may be in such a state or condition that bacteria change it easily, or it may be in such a condition that bacteria can change it but slowly. Most of the organic matter present in sewage is illustrative of the first condition, and that present in soil and loam is illustrative of the second condition. One of the objects of this paper is to show that organic matter of the first class can be so changed by bacterial agencies, working under favorable conditions in sewage filters of coarse material, that this matter practically takes its place in the second class; that this change can occur in filters operated at high rates; and that this matter, when changed to a more or less stable condition, can, as far as the effluent itself is concerned, safely remain in the effluent instead of being strained or filtered from it. That is, it will not under ordinary conditions rob this effluent of its dissolved oxygen and subsequently putrefy.

It was observed at the experiment station for a number of years that very turbid, poor appearing effluents from filters of coarse materials operated at high rates of filtration would often remain without change for an indefinite time, and that the matter coming from these filters in suspension in their effluents and rendering them turbid to eventually deposit as sediment, or washed from them purposely at times to relieve clogging, was apparently in a stable condition quite different from the condition of the putrefying, ill-smelling matters in suspension in the sewage itself when applied to such filters. The results obtained caused further studies to be made.

Series No. 1.—The construction and rate of operation of each of the filters of this series at this time was as follows: Filter No. 82 was constructed of cinders and was operated at the rate of 400,000 gallons per acre daily; Filter No. 103 was constructed of small pieces of coke and was operated at the rate of 660,000 gallons per acre daily; Filter No. 137 was constructed of broken stones and was operated at the rate of 800,000 gallons per acre daily; Filter No. 138 was constructed of broken stones and was operated at the rate of 480,000 gallons per acre daily; and Filter No. 133 was constructed of broken stones and was operated continuously in such a manner that air was not admitted and only putrefaction occurred within it, its rate of operation being 2,700,000 gallons per acre daily. All were contact filters with the exception of Filter No. 133. [The usual method of operating contact filters at Lawrence is as follows: The outlet is closed and the filter filled in four applications of sewage one hour apart, then allowed to stand full two hours, and drained slowly.]

The manner of making this experiment was as follows: from each filter a considerable volume of the effluent was collected and twelve one-gallon bottles were filled with each effluent. These bottles stood in the laboratory stoppered, and once a week the liquid in one of the bottles was taken for analysis.

Studying the results in detail it is seen that the dissolved oxgyen and the nitrates disappeared more or less rapidly from the effluents of Filters Nos. 82, 137 and 138, and the free ammonia increased in amount, as did eventually the oxgyen consumed, and the amount of nitrogen found as albuminoid ammonia decreased slowly, the appearance of each sample deteriorated and an increased odor was noticeable. The results with these three effluents showed that all organic matter in the sewage at the time that this sewage appeared as effluent at the outlets of these filters had not been sufficiently broken down by anaerobic action, and subsequently oxidized, to become stable. Oxidation and nitrification were occurring in the filters and a large portion of this organic matter present in the effluents was in a condition for slow oxidation to occur, but some of the organic matter present in these effluents was not ready for this under the conditions prevailing, without some further anaerobic bacterial action, and this occurred after the dissolved oxygen present in these effluents and the oxgyen of the nitrates had been consumed. That is, this matter had not, while passing through the filter, reached such a state of stable equilibrium that it was not affected appreciably by the bacteria of putrefaction, and hence these effluents deteriorated.

The organic matter in the effluent of Filter No. 103, however, which received septic sewage,—that is, sewage which had undergone prolonged anaerobic bacterial action before application to the filter,—had evidently passed the putrefactive stage. Slight oxidation only occurred in this effluent, the very slight odor primarily present disappeared and dissolved oxygen was present at the end of eleven weeks, notwithstanding the very considerable quantity of organic matter present. In other words, the organic matter in this effluent, although considerable in amount, as shown by the high free and albuminoid ammonia and oxygen consumed, was in a condition of fairly complete oxidation, the anaerobic action having been carried to its limit in the septic tank and in the filter, and good oxidation having occurred in the filter. The effluent of the anaerobic Filter No. 133 continued, on standing in the laboratory, to undergo putrefaction.

Series No. 2.—In this series the effluents of six filters were studied, the method of procedure being as follows: an average sample of the effluent of each filter was siphoned into five one-gallon bottles, each bottle being completely filled. These bottles then stood in the warm laboratory tightly stoppered, and analyses were made weekly for five weeks, using one of the samples for each analysis. The sample for the determination of oxygen dissolved was obtained by siphoning it from the bottle into the flask in which the determination was to be made as soon as the bottle containing the sample to be examined was unstoppered.

Two of the filters from which samples of effluent were collected were the intermittent-continuous Filters Nos. 135 and 136, constructed of broken stone, operated at a rate of rather more than 1,400,000 gallons per acre daily, and producing a highly nitrified effluent, but also containing considerable free ammonia and nitrogenous organic matter as albuminoid ammonia; one filter was No. 103, previously described, and operated this time at the rate of 520,000 gallons per acre daily; one filter, No. 133, was the anaerobic filter operated this time at the rate of 1,000,000 gallons per acre daily, and through which the sewage was passed for putrefaction to occur, as previously explained; and two filters, Nos. 137 and 163, were contact filters, one constructed of broken stone and one of coke, the rate of operation of these two filters being 960,000 and 720,000 gallons per acre daily respectively.

The changes in the effluent of each filter showed a variation as follows: the effluent of Filter No. 103 remained practically unchanged for reasons previously explained, and dissolved oxygen was present in it at the end of the period. The large amount of residual organic matter in the effluents of Filters Nos. 135 and 136 had been, owing to the anaerobic conditions prevailing in these filters, as evidenced by the high nitrates in the effluents, so changed by the bacteria and air that it was in a fairly stable condition. The effluents of these two filters—Nos. 135 and 136—contained dissolved oxygen at the end of the period of experiment notwithstanding the large amount of organic matter present, no putrefaction took place, odors did not develop, and the organic matter present remained practically without change. The effluents of Filters Nos. 137 and 163 contained less organic matter than the effluents of Filters Nos. 135 and 136, but were, nevertheless, in a much lower state of nitrification; dissolved oxygen either was not present or disappeared quickly, and putrefaction occurred. Instead of the amount of nitrogen present as free ammonia remaining constant, as in the effluents of Filters Nos. 135 and 136, it increased. The amount of oxygen consumed, instead of decreasing, increased eventually in the effluent of Filter No. 137, and the anaerobic actions in the bottles containing this effluent and the formation of gas were quite noticeable, odors developing also.

Series No. 3.—In this series of experiments the effluents were mixed with equal parts of river water containing dissolved oxygen. The gallon bottles were only partially filled and were allowed to stand in the laboratory without being stoppered. One sample of each mixture was analyzed each week for a period of four weeks. This manner of experimentation was used to make the conditions resemble, as nearly as possible upon a laboratory scale, the conditions prevailing if such effluents ran in large volumes into ordinarily pure ponds or rivers.

The effluents of Filters Nos. 103, 105, 136, 137 and 163 and sewage were experimented with. Treating the effluents in this way,—that is, mixing them with water containing dissolved oxygen and also allowing access of air,—they improved in character in every instance. The comparatively well-purified effluents of Filters Nos. 103, 135 and 136 showed slight or decided decreases in free and albuminoid ammonia and oxygen consumed, with an oxidation of organic nitrogen to nitrites and nitrates; the poorly purified effluents of Filters Nos. 137 and 163 showed remarkable improvement in the reduction of organic matter and the production of nitrites and nitrates, together with a reduction in color and odor.

Sewage, when mixed in this way and allowed to remain in contact with air, showed at first putrefaction for a period of two weeks, followed by rapid oxidation and the production of high nitrites. The explanation of this is that, although the surface of the sewage in the bottle was exposed to the air and hence oxygen must have been continually passing into the sewage, yet the organic matter on the surface water of this mixture consumed this oxygen so rapidly that the conditions below the surface favored the development of anaerobic bacteria, as shown by the formation of sulphuretted hydrogen, and only after this putrefactive action had been carried on for a certain period was the matter in a condition for aerobic bacteria to attain ascendancy and for oxidation to occur. During the first period, however, ammonium carbonate, determined as free ammonia, was forming, thus showing that some oxidation was occurring. The free ammonia increased during the first two weeks from 2.70 parts to 4.20 parts per 100,000, then in two weeks it fell to 1.15 parts, the nitrites and nitrates were reduced at first, then the nitrites increased in two weeks from .00 to 1.70 parts per 100,000.

Putrefaction did not occur in any of the samples of effluent and water, although decomposition or change in the presence of oxygen did occur. In the mixture of sewage and water, however, we first had putrefaction, followed by decomposition; that is, oxidation.

Series No. 3 A.—In this series the same effluents were experimented with as in Series No. 3, and the same mixture with river water was made, but the bottles were stoppered and air was prevented from entering. The samples then stood in the laboratory one month. In the effluents of Filters Nos. 103, 135 and 136 there was a continual slow oxidation of the organic matter, largely at the expense of the dissolved oxygen present, which was not entirely consumed, however, although some oxygen from the nitrates was also used. Odors did not develop in these effluents, but in fact became less. In the effluents of Filters Nos. 137 and 163, which were less satisfactorily purified than the effluents of the filters already named, decomposition occurred,—the oxygen of the water being quickly consumed,—followed by a putrefaction, the effluents becoming dark colored and having a strong odor.

At the end of the month the effluent of Filter No. 163 was allowed to stand with its surface exposed to the air in an open bottle. During the period of putrefaction the free ammonia had increased from 1.30 parts to 1.52 parts per 100,000, and the nitrates had decreased from .4700 to .0100 part per 100,000. During the month when air was allowed access to the surface of the effluent in the bottle the free ammonia decreased from 1.5200 to .0140 parts and the nitrates increased from .0100 part to 1.5900 parts per 100,000. The sewage quickly consumed the dissolved oxygen present in the water added, and continued to putrefy during the period of experiment.

Series No. 4.—In this series the effluents experimented with were from anaerobic Filter No. 133, the coarse and high rate Filters Nos. 134, 135 and 136, and the coke contact Filters Nos. 175 and 176. Five bottles of each effluent were filled and stoppered and placed in an incubator, the temperature of which was maintained at 80 degrees Fahrenheit, one sample being examined each day, the period covered being nearly five days.

The effluent of Filter No. 133, containing no nitrates or dissolved oxygen, putrefied, rapidly becoming black and ill-smelling, although the oxygen consumed from permanganate increased but slightly. The effluents of Filters Nos. 134 and 135, although containing but a small amount of dissolved oxygen at the beginning of the experiment, were three days in exhausting this oxygen, and subsequently a small amount of the oxygen of the nitrates was consumed. Neither effluent developed any odor nor changed in appearance. The effluent of Filter No. 136 deserves especial mention as it contained at the beginning of the experiment 1.24 parts per 100,000 of albuminoid ammonia, 9.03 parts of nitrates, and 22 per cent. of saturation of dissolved oxygen; and it is noticeable that, notwithstanding the enormous amount of organic matter present in the effluent determined as albuminoid ammonia, it was in an almost stable condition, the oxygen consumed from permanganate remaining practically constant during the period of incubation, the nitrates being reduced to 5.76 parts per 100,000 in the course of the experiment, the dissolved oxygen not being quite exhausted, and the effluent showing no change in appearance and not developing an odor.

The effluents of the coke contact Filters Nos. 175 and 176 were also incubated for the same period without any appreciable change of their organic contents, or the development of odors. The rate of operation of each of these two filters was at this time about 1,200,000 gallons per acre daily, and nitrification was active within them.

Series No. 5.—This series of experiments was with the effluents of Filters Nos. 135 and 136, the suspended matter having been largely removed by filtration of the effluents through paper. It was an incubation experiment covering a period of five days at a temperature of 80 degrees Fahrenheit, and the effluents remained practically unchanged.

Series No. 6.—Two experiments covering a period of five weeks, were made with the effluents of Filters Nos. 135 and 136, the effluents not being incubated, but standing in the laboratory for this period of time in gallon bottles open to the air. Both effluents improved in quality, the free ammonia of the effluent of Filter No. 135 decreasing from 2.00 parts to .90 part per 100,000 and the nitrates increasing from 4.02 parts to 5.10 parts per 100,000; the free ammonia in the effluent of Filter No. 136 decreasing from 4.00 parts to .90 part per 100,000, and the nitrates increasing from 1.56 parts to 3.43 parts per 100,000. Various other experiments of a like nature were made with similar results.

Summary.—The changes which go on in contact or other filters of coarse material are not always the same, but are dependent on the presence or absence of oxygen, and this in turn is dependent on various conditions, such as the character of the sewage, time of filling, time of contact and time of drawing off the effluent, etc. But that both anaerobic and aerobic actions usually go on in contact filters with the results described there can be no reasonable doubt. Further, that a limited period of anaerobic action, whether taking place within the contact filter or in the septic tank, is a favorable preparation of the organic matter for the subsequent action of the aerobic or oxidizing bacteria seems to be well proven. Thus we usually have within a contact filter both putrefaction and decomposition going on, and one or both of these processes is generally continued in the effluent. If the bacterial changes within the filter are very incomplete, the phenomenon of "secondary decomposition" (more properly called putrefaction) is the one to manifest itself in the effluent.

It is evident, moreover, from a study of all these results that the amount of organic matter determined as albuminoid ammonia and oxygen consumed in the effluent of a sewage filter constructed of coarse material, and operated at a high rate of filtration, is not a true index of the degree of purification of such an effluent, if we mean by purification the oxidation in the filter of the organic matter of the sewage to a more or less stable condition, and the production of an effluent which will not, when having free access to the air, putrefy. In order that such a stable effluent may be produced, it is only necessary that sewage shall have been for a comparatively short period of time in thin layers in contact with an abundance of air and that aerobic bacterial life shall have been active without the added straining out of organic matter obtained by sand or other filters of fine material. Such an effluent will show good nitrification and the presence of dissolved oxygen when running from the filter, irrespective of the amount of stable organic matter that it contains. These effluents, produced either by intermittent-continuous filters or by the best of contact filters, show little tendency to change when excluding air, and maintained at summer temperature for a considerable period. When mixed with water containing oxygen they invariably improve in quality. Even much poorer effluents improve when under the conditions last named, although they decompose and putrefy under the first-named conditions.

If such an effluent, showing good oxidation and nitrification occurring in the filter, contains dissolved oxygen, and habitually retains this dissolved oxygen for a considerable period, it is fairly certain that putrefaction will not occur in it under ordinary conditions, as when exposed to air. Slow oxidation may and probably will occur, this latter action improving the effluent without producing odors. This is abundantly proved by the experiments above described. If, on the other hand, the effluent as it runs from the filter does not contain dissolved oxygen, or if the oxygen present disappears with comparative rapidity, it may be taken as assured that such an effluent will putrefy eventually unless mixed with a considerable volume of water containing dissolved oxygen, even though it contains a smaller amount of organic matter, determined as albuminoid ammonia and oxygen consumed, than other effluents of the character just described, and even though a considerable amount of nitrates is at first present.

In the purification of untreated sewage by sand filtration there is upon many of these filters a constant tendency for surface clogging caused by the accumulation of the coarser and more stable organic matter of the sewage, and in order to keep these filters in operation, this matter either has to be scraped from the beds from time to time, or ploughing with periods of rest has to be resorted to. With an intermittent continuous filter of broken stone, on the other hand, much of this coarse organic matter passes through the filter, as already stated, and appears in the effluent, and surface clogging does not occur. Moreover, as this matter passes through and encounters aerobic conditions, it is, as illustrated by the experiments, oxidized to an innocous condition, and can be easily strained from the effluent at very high rates, if desired, leaving this effluent well purified, clear and highly nitrified, or about equal to the average effluents of sand filters, and produced by a rate of filtration many times as great.

Incubation Tests.—Studying the results of the many determinations of oxygen consumed from permanganate that have been made during these various experiments, we find (1) that the oxygen consumed from permanganate invariably decreases in effluents which are in such condition when collected that they undergo slow oxidation only; (2) that with effluents that finally putrefy the amount of oxygen consumed generally decreases at first, if any amount of nitrates and dissolved oxygen is primarily present in the effluent, to increase later when putrefaction occurs; (3) that in one instance, when the effluent of anaerobic Filter No. 133 was incubated at 80 degrees Fahrenheit for five days, the oxygen consumed increased only very slightly, although the change in the appearance and odor of the sample was very marked, owing to the putrefaction occurring within it; and (4) that in one instance, although the amount of oxygen consumed increased largely in this effluent when it was kept for a period of eleven weeks, yet during the first three weeks it decreased. These results, taken in connection with the complete analyses of the samples in each series, seem to throw some doubt upon the significance of the so-called five-day incubation test with the determination of oxygen consumed only, used to determine the stability or instability of the organic matter of the effluents of sewage filters, that is, to determine their liability to undergo the so-called secondary decomposition. This determination is very much depended upon, however, in England, to show the character of the effluents of sewage filters, as being a much shorter way than complete analyses of these effluents. It would seem, however, that in most instances a determination of the dissolved oxygen present at the beginning and the end of the period of incubation, together with observations of the change in appearance of the sample, if any occurs, would be a more satisfactory and simple test.

Letters to the Editor.

COMPUTATIONS FOR RIO GRANDE BRIDGE.

Sir: In your issue of November 8, referring to calculation of stresses, Rio Grande Bridge, Pacific Railway of Costa Rica, it is stated that the matter is clearly and concisely explained by Mr. Aus. I fail to see it.

Mr. Aus gives the formula:

$$H = \frac{\Sigma\, S_0\, S_1 \frac{m}{a}}{\Sigma\, S_0^2 \frac{m}{a}}$$

In which (as corrected on page 515 of the issue of November 29), H = horizontal thrust; S_0 = total stress in a member from horizontal unit reaction only; S_1 = total stress in a member from vertical unit reaction; m = length of a member, and a = area of cross-section of a member.

The information is given that this formula was originated by Professor Maxwell and explained and elaborated by Professor Greene. The writer was struck by the bold way in which, when making deductions from his equation (5), Mr. Aus writes:

$$h = \frac{v\, S_1\, S_0\, \frac{m}{E\,a}}{S_0^2 \frac{m}{E\,a}}, \text{ and}$$

$$\Sigma\, h = H = \Sigma \frac{v\, S_1\, S_0\, \frac{m}{E\,a}}{S_0^2 \frac{m}{E\,a}} = \frac{\Sigma\, v\, S_1\, S_0\, \frac{m}{E\,a}}{\Sigma\, S_0^2 \frac{m}{E\,a}}$$

Making things clear, it is proper to deduce the fundamental formula. Assumed an arch as given by Mr. Aus.—Stresses to be determined. Removing one condition (that is, removing any one single member, or the horizontal thrust) makes the structure determinate, subject to ordinary stress calculations. Suppose, for a trial, the horizontal thrust H is removed and instead an external force X substituted. Then the stress S in any member must appear under the form

$$S = S_0 + S_1 X \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots (1)$$

This is evident from the fact that the stress S is a linear function of the loads which produce it. Knowing the form under which S must appear, only one more condition is needed to determine X. This condition is supplied by the law of virtual work, first stated, actually and distinctly, by Lagrange (1736-1813), which law, for present purposes, can be written:

$$\Sigma\, P\, \delta + \Sigma\, C\, \Delta\, c = \Sigma\, S\, \Delta\, m \ldots\ldots\ldots\ldots\ldots (2)$$

Where P = any exterior force acting on the structure; δ = movement of this force in its own direction; C = a reaction of any support; Δc = movement of C in its own direction; S = stress in any member of structure; and Δm = change of length of same member. It must be noted that P must correspond to C, which must correspond to S; also, δ must correspond to Δc, which must correspond to Δm. But it is important to note that neither P nor δ, nor C nor Δc, nor S nor Δm are corresponding quantities, necessarily. This is stated summarily, but having understood equation (2) the missing condition of our calculation can be supplied.

Returning to the arch of Messrs. Cooper and Aus: Remove the horizontal thrust and substitute an exterior force X. Applying equation (2) it is written:

$$-1.\, \Delta\, l = \Sigma\, S_1\, \Delta\, m \ldots\ldots\ldots\ldots\ldots (3)$$

Where 1 and S_1, Δl and Δm are corresponding quantities. One familiar with the theory of elasticity will know the equation:

$$\Delta\, m = \frac{S\, m}{E\, a} + e\, t\, m \quad \ldots\ldots\ldots\ldots (4)$$

Where Δm = change of length in any member, as before; S = stress in same member; m = length of same member; a = area of cross-section of same member; E = modulus of elasticity; e = coefficient of expansion; and t = change of temperature.

From equation (1)

$$\Delta\, m = \frac{[S_0 + S_1\, X]\, m}{E\, a} + e\, t\, m \ldots\ldots (5)$$

and from equation (3)

$$-\Delta\, l = \Sigma\, S_1 \frac{[S_0 + S_1\, X]\, m}{E\, a} + \Sigma\, S_1\, t\, e\, m,$$

X being constant with reference to other quantities under the summation mark, also E and t and e.

$$X = -\frac{\Sigma\, S_1\, S_0\, \frac{m}{a} + e\, t\, E\, \Sigma\, S_1\, m + E\, \Delta\, l}{\Sigma\, S_1^2 \frac{m}{a}} \ldots (6)$$

Which is the general formula for the thrust X. Assuming the temperature and span length constant, equation (6) becomes, for external loads only,

$$X = -\frac{\Sigma\, S_1\, S_0 \frac{m}{a}}{\Sigma\, S_1^2 \frac{m}{a}} \ldots\ldots\ldots\ldots\ldots (7)$$

It is not necessary to be confined to any particular condition, such as the horizontal thrust. In fact, any member of the arch shown by Mr. Aus may be removed, and the external force X substituted and written, when all else but external loading is neglected:

$$X = -\frac{\Sigma\, S_1\, S_0 \frac{m}{a}}{\Sigma\, S_1^2 \frac{m}{e}}$$

Where X = stress in member removed; S_0 = stress in any member for given loading and X = 0; S_1 = stress in any member when X = 1 and assumed external loading removed; m = length of any member; and a = area of cross-section of same.

Even interchanging S_0 and S_1 this does not agree with Mr. Aus' definitions as above.

That Mr. Aus neglects the quantity $\frac{m}{a}$, or in fact, makes this quantity = 1 is a doubtful expedient. This proposition has been tested, numerically, and involves a considerable error, making the entire calculation of doubtful utility, especially in arches like that of Mr. Aus. But it is not necessary to question this proceeding so much as his "approximate formula."

Let the formula for X, or the horizontal thrust, when only one elastic member *a* in the structure is assumed, be deduced:

It is written again, as per equation (2)

$$-1 \times \Delta\, l = \Sigma\, S_1\, \Delta\, m$$

in which case, when only one member is elastic, it becomes:

$$-\Delta\, l = S_{1(a)}\, \Delta\, m_{(a)}$$

Δm according to assumption being = 0 for every member except *a*. Having immovable supports $\Delta l = 0$, therefore $S_{1(a)}\, \Delta m_{(a)} = 0$. As $S_{1(a)}$ must necessarily be a finite quantity $\Delta m_{(a)} = 0$, or the stress in member *a* : $S_{(a)} = 0$. In plain English, there is no stress in member *a*, which alone was assumed elastic. But $S_{(a)} = S_{0(a)} + S_{1(a)}\, X = 0$, and for member *a* only being elastic,

$$X = -\frac{S_{0(a)}}{S_{1(a)}} \ldots\ldots\ldots\ldots\ldots\ldots (8)$$

The result of above mathematical argument is primarily evident; for, as neither the abutments can move, nor any member but *a* change length it is plain that if the arch stands, as it does, no deflection or change of position can take place in any point. Hence, no change in length of member *a* is possible, that is to say, *a* can have no stress. This fact shows that, when considering only one member of the structure as elastic, the horizontal thrust, or X, obtained, must necessarily be the X for a three hinged arch with one hinge opposite, or in the moment point of, member *a*. Therefore the value of

$$X = -\frac{S_{0(a)}}{S_{1(a)}}$$

as obtained must be one which makes stress *a* = 0.

Having understood this, it becomes increasingly difficult to understand not only the "approximate formula" of Mr. Aus, but it is also difficult to understand the deduction of equation (7) attempted by Mr. Aus and Professor Green, which deduction originally is attributed to Prof. Maxwell, as per Cyclopedia Britannica.

To further elaborate this point equation (7) may be written:

$$X = -\frac{S_{1(a)}\, S_{0(a)} \frac{m_a}{a_a}}{\Sigma\, S_1^2 \frac{m}{a}} - \frac{S_{1(b)}\, S_{0(b)} \frac{m_b}{a_b}}{\Sigma\, S_1^2 \frac{m}{a}} - \text{etc.}$$

The indices a, b, etc., denoting the various members of the structure. In this form of equation (7) we see that when the whole structure is assumed elastic, the contribution of any member *a* to X is

$$= -\frac{S_{1(a)}\, S_{0(a)} \frac{m_a}{a_a}}{\Sigma\, S_1^2 \frac{m}{a}} \ldots\ldots\ldots\ldots\ldots (9)$$

Even, making the unwarranted assumption of Mr. Aus that $\frac{m}{a} = 1$, it would appear from equation (8) that, multiplying dividend and divisor by $S_{1(a)}$

$$X = -\frac{S_{1(a)}\, S_{0(a)}}{S_{1(a)}^2}$$

$$\text{should be} = -\frac{S_{1(a)}\, S_{0(a)}}{\Sigma\, S_1^2}$$

Which is to say, in one case the quantity $S_{1(a)}\, S_{0(a)}$ is divided by $S_{1(a)}^2$ and in the other case by ΣS_1^2. Or, stated explicitly, in one case the divisor is $S_{1(a)}^2$ for one member, and in the other case the divisor is ΣS_1^2 extended to all members of the structure. These two quotients cannot be equal. Nor is this proceeding materially improved by assuming, as Mr. Cooper, two symmetrical elastic members:

For let the formula of X for two symmetrical elastic members *a*, *b*, be deduced:

It is written again:

$$-1 \times \Delta\, l = \Sigma\, S_1\, \Delta\, m$$

and as before

$$S = S_0 + S_1\, X$$

and

$$\Delta\, m = \frac{S.m}{E\, a}$$

Neglecting temperature, which for

$$\Delta\, l = 0$$

as before, gives:

$$\Sigma\, S_1\, [S_0 + S_1\, X]\, \frac{m}{E\, a} = 0$$

Or, for only two symmetrical members, *a* and *b*, being elastic:

$$X = -\frac{S_{0(a)} + S_{0(b)}}{2\, S_{1(a)}} \ldots\ldots\ldots\ldots\ldots (10)$$

in view of the fact that S_1, m and a are the same for both members. Also that $S_{1(a)} = S_{1(b)}$ both are put $= S_{1(a)}$ in the divisor.

This formula is the same as the one given by Messrs. Cooper and Aus for a special case. Here again is met with the same difficulty as before. That is, the contribution to X of two members, *a* and *b*, using equation (10) is:

$$X_{(a,b)} = -\frac{S_{0(a)}\, S_{1(a)} + S_{0(b)}\, S_{1(a)}}{2\, S_{1(a)}^2}$$

Obtained by multiplying dividend and divisor by $S_{1(a)} = S_{1(b)}$ as before. This expression of X must be, according to equation (9), and putting $\frac{m}{a} = 1$:

$$X_{(a,b)} = -\frac{S_{0(a)}\, S_{1(a)} + S_{0(b)}\, S_{1(a)}}{\Sigma\, S_1^2}$$

But the two quotients cannot have the same value. It is evident on the face of it. It is also evident that an "approximation" of this kind will lead to results of doubtful value.

Yours truly

Chicago, Ill., Nov. 24, 1902. E. S—n.

[The above communication was submitted to Mr. Aus, and his reply is printed below.]

Sir: I have read with much interest the criticism of my attempt at a popular demonstration of the derivation of the formula for computing the horizontal reaction in a spandrel arch. The writer in his criticism of the mathematical work in developing the formula can hardly seriously believe that I mean to say that the summary of a series of fractions is equal to the summary of the numerators, divided by the summary of the denominators. I certainly did not say so, but may be subject to criticism for not having more fully illustrated the method of arriving at the final formula for H.

As Mr. S—n undoubtedly knows the summation of the elongations due to stress in the individual members of the arch is made, and this elongation being equal to 0, the equation for H is found. Nor is Mr. S—n right in stating that I assumed $\frac{m}{a} = 1$. It was only assumed as an approximation that all members were of the same length and cross section, in order to arrive at the approximate stress in the members, so that the approximate section of these members could be found, and by introducing these approximately correct sections in the formula for H find the actual sections.

However, the real question is not whether I in a somewhat hurried explanation that in no way claimed originality (being, as already stated, fully demonstrated by Professors Clerk Maxwell and Green) did or did not succeed. The question that is of interest to the profession is, whether the formula $H = \dfrac{\Sigma\, S_1\, S_0\, \frac{m}{a}}{\Sigma\, S_0^2\, \frac{m}{a}}$ is or is not the proper value for the horizontal reaction in the two-hinged spandrel arch. That the formula is accepted by the authorities above mentioned and has been used by eminent engineers in proportioning such arches, is, of course, no proof of its absolute correctness, but is, on the other hand, a fairly safe precedent to go by for practical purposes.

The assumptions on which the formula is built are, of course, to some extent empirical, and the result consequently not theoretically correct, but the question is, how to calculate this form of bridge in a practical and yet theoretically correct manner. How this can be done by the formulas developed by Mr. S—n I fail to see, and am sure that I voice the opinion of many engineers who have read Mr. S—n's discussion, when I request him to give explanation of the method he proposes to employ.

Respectfully,

GUNVALD AUS.

New York, Dec. 3, 1902.

TILE DRAINAGE OF TOWNS.

Sir: The writer would like to learn whether any cities or towns have been successfully tile drained to prevent water creeping into basements. Accounts of experience in any part of the world, together with statements of conditions existing before and after the execution of the work would be acceptable; likewise information as to where literature on the subject can be procured.

Yours truly,

December 15, 1902. IRRIGATION ENGINEER.

[Replies may be addressed to The Engineering Record.]

Effect of River Regulation on Down-stream Water Level.

Interference with streams has been one of the most fruitful sources of litigation. Numerous more or less effective efforts have been made by the engineering profession to reduce to computation some of the results of changes proposed in water courses. Approximations only can be attained with the data which can be economically procured for problems of this class. In the "Centralblatt der Bauverwaltung" Herr E. Krüger publishes an investigation of the complaints almost invariably made when the regulation of a waterway is undertaken. These claims are generally that by improving the flood discharge of the up-stream section the high water in the down-stream section is raised above its former levels. The author finds that these claims rest on exaggerated assertions and inaccurate conceptions, and presents methods for computing some of the effects of steam regulation.

If an up-stream section of a waterway is improved by the clearing or widening of the channel and the flood discharge is thereby increased, the conditions of the down-stream section will not be disturbed as long as the discharge remains in a state of permanence. This is because the drainage area has remained unchanged by the stream improvement and it therefore will discharge the same amount of water as before. The average velocity of the water only can be increased, and since the velocity of the high-water discharge is a function of the discharge, it can also be increased. In waterways in which the high-water swell extends over a long distance this effect is small; if, however, the overflowing water has not yet reached its state of permanence, but rises and falls, the conditions of discharge in the lower section will be changed. Let Figure 1 represent

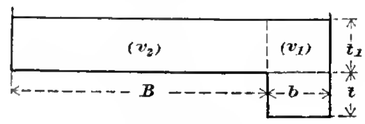


FIGURE 1.

the section of a stream and its adjacent shores, t being the depth of the stream and t_1 the depth of the water overflowing the shores, then the discharge will be:

Due to the stream channel, $Q_1 = b(t + t_1)\,v_1$
Due to the inundated shores, $Q_2 = Bt_1\,v_2$

Total, $Q = Q_1 + Q_2$

During the time T of the rise of the water from t to t_1 the whole quantity of water coming from up-stream was not discharged into the down-stream section as the inundated area had to be filled by the quantity $a = (B + b)t_1$ per unit of length of the valley. If b be neglected as small, $a = Bt_1$. Thus of the whole regulated up-stream section of length l the inundated region retains the total amount $A = Bt_1\,l$.

The storage of this amount of water reduces the discharge at the beginning of the down-stream section by $q = \frac{Bt_1\,l}{T} = Bl\Delta t$, in which $\Delta\, t$, denotes the rise of level per second. If the water is falling, the discharge in the down-stream section is increased by $q^1 = B\, l\, \Delta^1\, t_1$ because the water falls according to different laws from those which govern its rising.

The discharge per second in the down-stream section is then:

During rise, $Q = Q_1 + Q_2 - q$
During fall, $Q' = Q_1 + Q_2 + q^1$

The effect of the quantity A retained by the overflow area on the discharge can be seen from the above equations. This effect will also be felt in all streams which do not overflow but lose their permanency of flow, but it will be so small as to be negligible.

The author also gives a method for determining the changes of level. The values $\Delta\, t$ and $\Delta^1\, t_1$ can be found by observation and l is known. If the overflow region is irregular the length of the stream is divided into reaches and comparative cross-sections are taken. From these cross-sections the width of overflow B can be determined for different water levels and $q = \Sigma\, B\, l\, \Delta\, t$.

The relation t_1 and q are represented graphically in Figure 2. The discharge in the down-

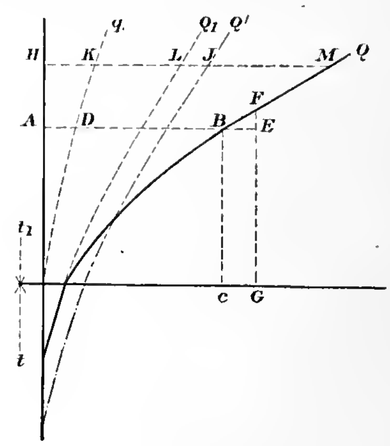

FIGURE 2.

stream section $Q = Q_1 + Q_2$ as well as the discharge Q' in the up-stream section are also plotted. t and t_1 are the ordinates, q and Q the abscissas. If in a regulated stream the overflow begins with the discharge $Q' = HJ$ the rise of level in the down-stream section can be determined as follows: Before regulation $Q = AB$, $t_1 = BC$, then $q = AD$ and the discharge of the down-stream section after regulation must be $Q = AB + AD = AE$. For the section down-stream which has not been regulated, this corresponds to $t_1 = FG$ and the rise of level is $s = FG - EG = EF$.

The wider the overflow area in the unregulated reach and the steeper the slopes of the stream, the flatter the Q-curve will be and the smaller the effect of q on the rise of level. If the discharge $Q' = HJ$ is exceeded the regulated stream will overflow and the overflow region will also take a part in the discharge the same as before the regulation. In the improved section no further rise of the water takes place until the amount discharged has increased from HJ to HJ + LM and has exceeded the same. For all discharges between HJ and HJ + LM the greatest value of q is constantly equivalent to HK.

The Experiments on the Filtration of the water supply of Springfield, Mass., were described at some length in The Engineering Record of July 12. Full details of the many analyses made, which were summarized in that article, are given in the official report of the chemist, Mr. H. W. Clark, to the Massachusetts State Board of Health, and are published in the 1901 report of the board, in which form they are available to those specially interested in this unusual case.

Iron in the Water Supply of Attleborough, Mass., led to an investigation by the State Board of Health during 1901. It was found that the trouble was almost wholly due to the action of the water on the service pipes, nearly all of which were of galvanized iron, and not to action of the cast-iron mains. Several service pipes of galvanized iron where complaints had been made of the character of the water were replaced with pipes lined with cement or tin, and no further trouble from iron was observed.

Retempering Cement Mortar: Modulus of Rupture of Concrete.

In the construction of the Manhattan Railway Company's power station, at Seventy-fourth Street and East River, New York City, during the past two years, about 40,000 barrels of cement were used, all of which was carefully inspected, over 3,500 briquettes being made and broken. In the course of this work several special investigations were made, which are described in a paper by Mr. Thomas S. Clark, resident engineer in charge of construction of the power station, printed in "Cement and Engineering News" for October, from which the following paragraphs have been taken:

It is to be regretted that the practice of retempering Rosendale cement mortar after it has lain in the mason's tubs over the noon hour, is a frequent practice by builders in New York City. It is not a question whether a wall built with retempered Rosendale cement mortar will fail or not, but it is a question of getting the best wall for the money expended. To prove to the satisfaction of all concerned that Rosendale cement mortar is injured by retempering after 60 minutes, the experiments shown in the table were made. All briquettes in like sets of same brand were made from the same bag of cement and their treatment was exactly the same, except the retempering, which was done at the end of the hour, and enough water added, as in practice, to bring the mass back to its original consistency.

*Per cent. of water given is the initial wetting.

The same disastrous results were obtained even when the cement was moistened every fifteen minutes of the hour. Contractors have argued that if a little fresh cement is added the mortar is as good as it was originally. It is quite true that the strength is increased, but the old mortar must be considered as almost inert material. It cannot be supposed that the fresh cement has any life-giving effect upon the particles of the old cement which has passed through the first stages of set. Builders may be able to point to walls where this practice was in vogue, but there is no question that the wall built where it was not allowed is the better wall, will endure longer and stand more shock. With several brands of Portland cement under the same treatment the machine used failed to show any injury done.

As with Rosendale cement, there must be a limit where retempered Portland will fail, and we are inclined to believe that it is somewhere within the second hour of standing. That the retempered Portland did not fail may be explained by the fact that the time of active set of Rosendale is shorter than that of Portland. The safest rule is to allow no retempering under any circumstances.

It is safe to assume that concrete a little too wet is ofttimes better than that which is too dry, especially when laid in warm weather, but when forced to lay Portland concrete in freezing temperatures, the least possible water used the better.

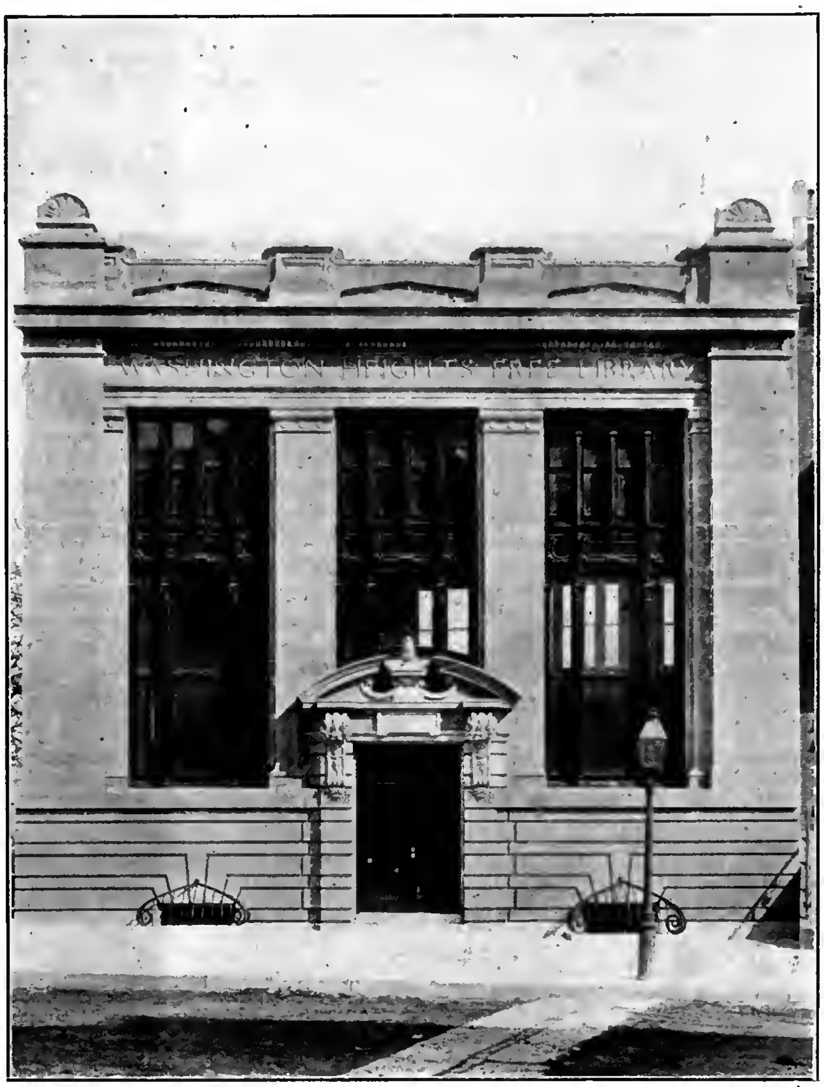
In order to determine roughly the relation between the tensile strength of neat cement, cement mortar, stone and cinder concrete and its so-called modulus of rupture when acting as a beam under a concentrated center load, briquettes and beams were made, the latter with rectangular cross section, using the same cement and aggregate for like sets and subjecting them to exactly the same treatment. After breaking the briquettes by direct tension, and the beams by cross-bending, it was found that the substances mentioned showed, on a fair average, that the modulus of rupture of cross-breaking was about one and one-half times greater than the strength in direct tension.

The fracture in the beams often showed the place of rupture passed directly through the stones of the aggregate, so the strength of the stone was largely a factor of the strength of the beam.

Referring to the Waste of Water in New York City, Mr. Thomas A. Fulton, in an address to the commission of engineers appointed by Mayor Low to investigate the supply, humorously summed up the position of the City Club as follows: "Opposed as we are to the acquisition of new watersheds by and for this city until the present supply is fully exploited, we would yet urge one exception. There is one watershed which is very accessible, will cost very little to acquire and will yield four or five times as much water as any other area of like dimensions. It is only 21 square miles in extent,—Manhattan Island."

Heating in the Washington Heights Free Library, New York.

The building now occupied by the Washington Heights Free Library is on the east side of St. Nicholas Avenue, near 156th Street, New York City. It is not a very large building and consequently it was decided to warm and ventilate it without mechanical means for producing the flow of air. The heating is done for the most part by indirect radiation, which, by taking its air supply from outdoors, provides the desired fresh air for the ventilating. A downward system of circulation is employed, the supply registers being located in the walls and the exhaust registers in the floor. A current of air is maintained through the exhausts by furnishing heat to the interior of the riser shafts to the roof, so that a natural chimney action is thereby ensured.

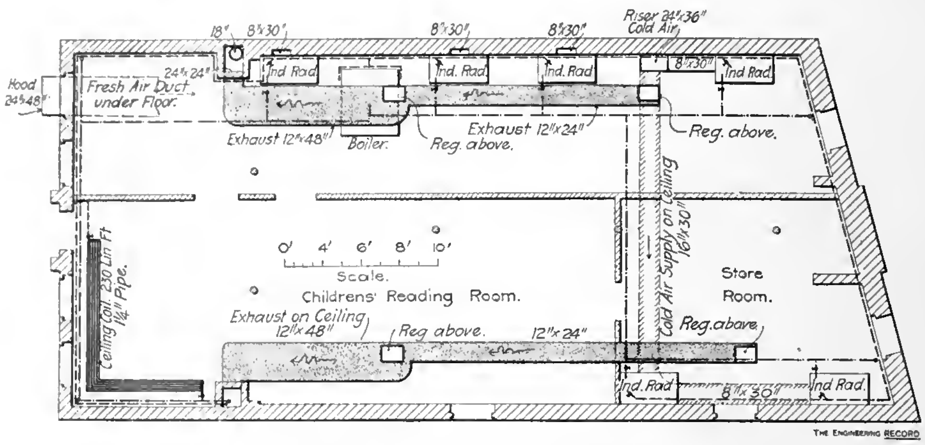


WASHINGTON HEIGHTS FREE LIBRARY.

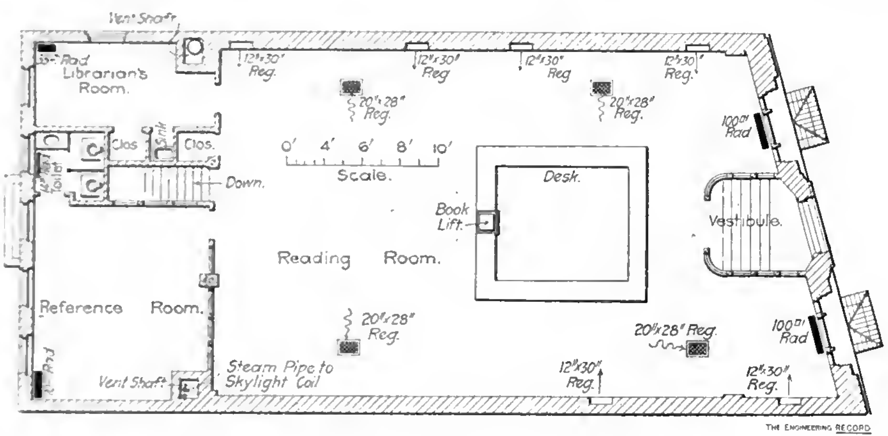
The library was incorporated in 1868 and existed mainly by private subscription until October, 1901, at which time it was conveyed over to the greater library, officially known as "The New York Public Library, Astor, Lenox and Tilden Foundations," with the condition that under the new control a library must be perpetually maintained in the section which it now supplies. In May of 1901 the library was moved into its new quarters on St. Nicholas Avenue. The accompanying reproduction from a photograph of the front shows its street facade. The building has a frontage of 41 feet and a depth, its longer dimension, of 89½ feet, the ground area occupied being about 3,740 square feet. It was erected at a cost of $30,000, and the site cost another $30,000. Its expenses are $6,000 a year, and it supplies a population of about 75,000. The total number of volumes in the library at the time of the last report was 18,664, and it is calculated that its circulation for the current year will be more than 100,000 volumes.

The basement, a plan of which is included in the illustrations, is given up to the heating plant in one-half and a children's reading room and a store room in the other. The main floor, shown in another plan, consists of one large reading room with a mean height of 29 feet, and a rear extension of less height containing a reference room and a room for the librarian. An idea of the form of the interior may be obtained from the sectional elevation from front to rear. The book stacks are ranged along the walls of the reading and reference rooms. They are of steel, manufactured by the Art Metal Company, and have adjustable sheives. The steel construction, besides being fire-proof, has, of course, the advantages of compactness and lightness. The main reading room is lighted from the ends by large windows and also has a skylight in the center of the ceiling. The latter has been stained because it was found to give a light that was too glaring; the elevated position of the building, with nothing to cut off the light at either end, making the windows amply sufficient.

The indirect and direct radiation for the heating are supplied with steam by a No. 110 Thatcher sectional boiler, consisting of ten sec-



Basement Plan, Showing Ducts.



Plan of the Main Floor.

tions. It has a grate surface of 13½ square feet and a rated capacity of supplying 3,200 square feet of radiating surface. It is covered with a jacket of asbestos cement and has the usual fixtures and fittings, including an automatic damper regulator. The boiler is fed through a feed and a check valve by water taken directly from the city service, and may be drained through a valve to a blow-off tank. The complete piping system is dripped through a trapped discharge pipe to the blow-off tank or may be emptled entirely into it. The waste gases are taken through a horizontal cylindrical smoke connection 20 inches in diameter, of No. 12 gauge black iron, and lagged with 2 inches of air-cell magnesia covering. This smoke duct connects to the base of an 18-inch flue of the same material, extending to the roof through an exhaust air-shaft. This portion is unlagged so that its heat may render positive the upward draft of impure air within the shaft. The stack is supported at the base 4 feet above the boiler room floor on an angle-iron frame and contains a 16x22-inch cast-iron clean-out door.

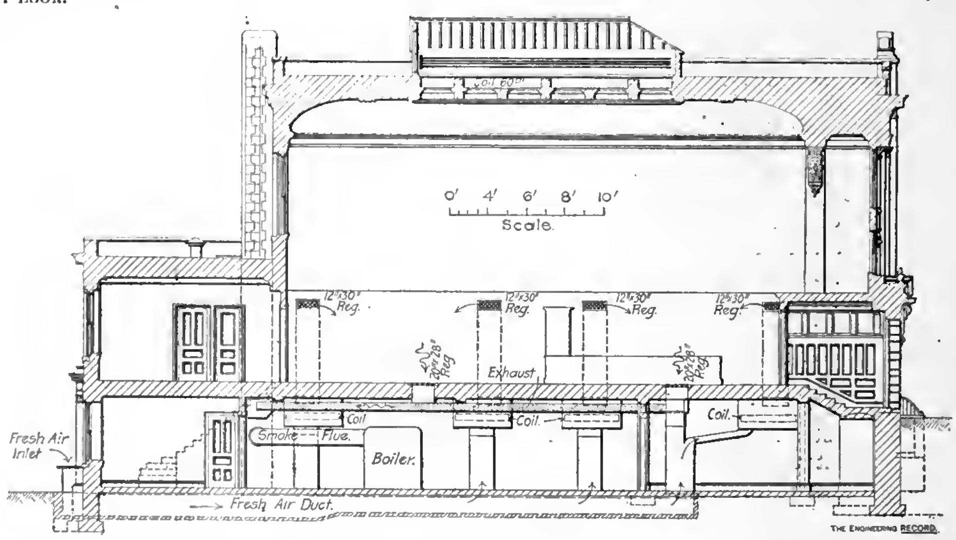
From the steam outlet in the boiler a single main is taken, from which are run the branches to all radiators, indirect stacks and coils. In general the supply pipes are 2 inches in diameter, decreasing where allowable, and the returns are one size smaller than the supplies; the smallest being 1 inch in diameter. Except in locations where their radiation is desirable, the pipes and fittings are covered with magnesia lagging.

The fresh air inlet to the indirect system is at the rear of the building near the south side. It is 24x48 inches in area and protected by a galvanized iron hood with heavy wire netting directly over the intake. From its inlet the air passes through an air duct or tunnel below the basement floor, containing a damper, and is taken through branches from this to four flues along the south wall with indirect stacks in their bases. A galvanized-iron cross-duct on the basement ceiling near the front of the building carries fresh air to two more flues containing indirects along the north wall near the front. The indirect heaters are hung from the ceiling of the basement and each has a total surface of 250 square feet.

A vertical riser from each indirect stack leads to a single register in the main story. The registers are located 7½ feet from the floor and have 12x30-inch openings, which are controlled by ordinary slat dampers. The stack casings are provided with bottom doors to give access to the stacks and are made of No. 22 galvanized iron. The connections from the casings to the main duct and to the registers above are made of the same material and the flues on the main floor are surrounded with metal lath.

The heating of the main floor is assisted by a few direct radiators. Two with 100 square feet of surface each are on either side of the entrance. There is also one in the reference room having 70 square feet of surface, one in the toilet having 14 square feet, and one in the librarian's room having 35 square feet. Under the skylight in the ceiling of the large room is hung a pipe coil having 60 square feet of radiating surface. The basement is well heated by the proximity of the boiler room and the bases of indirect flues. The most exposed corner has a ceiling coil of 1¼-inch pipe containing 100 square feet of surface. All radiators, stacks and coils are equipped with automatic air valves and ordinary valves on the supply and return ends.

In the proportioning of pipes, radiators, etc., it was designed to provide a free circulation of steam throughout the apparatus with a pressure as low as one pound. The designing and disposing of parts was also calculated to maintain the building at 70 degrees in zero weather with a pressure of steam not to exceed 5 pounds.



Longitudinal Elevation.

The exhaust registers for the removal of vitiated air are located in the floor of the reading room and have no dampers so that they cannot be closed. There are four of them, two on each side of the room, 20x28 inches in size. On the ceiling of the basement these are connected into two duct systems; the north side venting into the shaft containing the smoke stack and the other to one in which the uncovered steam supply pipe to the skylight coil is carried.

The architects for the building were Messrs.

Benson & Brockway, of New York, and the heating was laid out on the general lines proposed by them. All of the contract work was under the charge of Messrs. Isaac A. Hopper & Sons, the heating contract having been sublet to Messrs. Baker, Smith & Company, of New York.

Recent Municipal Works at Aldershot, England.

Abstract of a paper by Mr. Nelson F. Dennis, Assoc. M. Inst. C. E., before the Association of Municipal and County Engineers.

The government camp at Aldershot, established in 1853-4, and originally a collection of wooden huts, now consists of blocks of brick and stone buildings and well-made roads and paths. Thought and attention has been given, in the laying out of the camp, to the provision of the many things calculated to make the life of the soldier cheerful, as well as useful. There are provided for him reading-rooms, libraries, recreation-rooms, gymnasiums, swimming bath, recreation grounds, and various institutions where he can improve his general knowledge.

The area of the Aldershot urban district is 4,177 acres, and the taxable value of the property is about $630,000. The water supply is under the control of the Aldershot Gas and Water Company. The supply is derived from wells sunk into the chalk, and is ample in quantity and good in quality, although somewhat hard. The water charges are based upon the rental, being 6 per cent. for houses renting for less than $250, 5½ per cent. for places renting at $250 to $500, and 5 per cent. for those commanding higher rents. The gas costs about 65 cents per 1,000 cubic feet. The town has an official testing station for the gas, and the candle-power must not be below 15, as determined here.

Sewage Works.—The "contour sewer," so called, was constructed in 1901, and provides for an area of 430 acres. Commencing at the sewage works, 18-inch pipes were laid for 5,320 feet at a gradient of 1 in 410, 2,000 feet of that length being laid in tunnel, at a depth of from 25 to 43 feet. Shafts were sunk every 150 feet, which were afterwards bricked up, circular in plan, for man-holes. The progress of the work through the tunnel was slow, owing to the loose, watery nature of the soil in a portion of the work; foul air had also to be contended with. Where the sewer was laid at depths from 9 to 15 feet the pipes were embedded in concrete to the half-diameter, and at depths above 15 feet the pipes were encased in concrete. From the tunnel the size of the sewer is diminished to 15 inches, with a fall of 1 in 330, for a length of 2,640 feet. The remaining 3,470 feet is of 12-inch pipes, and the gradient 1 in 73.

The rain water from yards and the back portions of the roofs of houses flows into the sewers, but the front roof water and street water is collected on the separate system, which has been laid down in nearly every road in the district. The main surface drainage is discharged at two outfalls. Since 1899 there have been erected 47 steel columns at the curb line for sewer ventilation. They are 8 inches in diameter for the lower half, 6 inches for the upper half, and 30 feet high. They have been found to be satisfactory.

Since the introduction of the bacteria system and the abandonment of chemicals the effluent from the disposal works has given no cause for anxiety. The experimental period, usual when the bacteria system is under consideration, was terminated about four years ago, and it was determined to adopt the contact beds for the treatment of the Aldershot sewage. Since then sufficient primary beds, and half the area of the secondary beds, have been constructed for the treatment of the whole of the ordinary flow of sewage. It has been found that the quality of the effluent is impaired by the compliance with the Local Government Board's requirement to pass it over land before discharging into the Blackwater. The land at the town disposal works is not good, being flat, with its surface very little above that of the river. The subsoil water at times is within 2 feet of the surface for a considerable area. Rye grass, for which there is little demand, is the only crop grown.

The sewage (the dry weather flow being about 600,000 imperial gallons per day) is raised from the pump well a height of 18 feet, by means of centrifugal pumps, to a detritus chamber 24 feet long by 10 feet wide; and, without further treatment or screening, is conveyed along a carrier of brickwork, lined with vitrified bricks and supported on arches, to the series of primary beds, from which it is passed after contact, varying from 2 to 3 hours according to the strength of the sewage, on to and through the secondary beds with continuous flow. The effluent then enters a carrier dug in the earth, 6 feet wide, along which it travels for a distance of 600 yards to the outfall. The average rate of charging the primary beds with sewage is 2¼ times per day.

There are 13 primary beds, three of which are each 138 feet long, 24 feet 6 inches wide, and 5 feet 3 inches deep, and ten, each of the average dimensions of 57 by 35 feet by 4 feet 6 inches deep—a total area of 3,344 square yards. The beds are enclosed with brick walls, 14 inches thick, with buttresses. The bottoms are of Portland cement concrete. The sewage is admitted to each of these beds by gates fitted in the middle of the long side, and falls over some large clinker lumps into the filter. Neither distributors nor sprinklers are employed. The filter medium consists of furnace clinkers, graded from large lumps at the bottom, affording good drainage, to fine ashes at the top, and is 1 foot 3 inches thick. The outlet valves, at the opposite side to the inlets, upon being opened permit the primary effluent to flow into the low-level secondary bed carrier. The primary effluent can be controlled in this carrier by gates so as to flow into any of the secondary beds, of which there are four at present—two, each 100 by 57 feet by 2 feet deep (four more of this size are to be constructed); and two, 105 by 85 feet by 1 foot 9 inches deep. The filling of the secondary beds consists of a layer of coarse clinker at the bottom and the top 1 foot 2 inches of fine ashes.

Mr. Dennis, who is the engineer for the town, has come to the conclusion that the disposal of a town's sewage on the contact method cannot be left to an automatic machine, neither can it be entrusted to the inexperienced laborer. Elaborate arrangements of valves, feeding troughs, etc., he does not consider essential.

The surface of the primary beds for about 10 inches is delved over once a fortnight, and the deposit on the top near the inlet is raked off and burnt in the destructor. The total accumulation thus removed amounts to an average of 5 barrows per day for the whole of the primary beds. The secondary beds are harrowed once a week. Two men are constantly employed on this work. The effluent from the beds has been good at all times. The cost of the primary beds, including carriers, has averaged $730 each, complete, and the secondary beds, $1,070 each.

During wet weather, owing to the diluted state of the sewage, the period of retention in the primary beds is reduced to about 1½ hours, and the excess flow is passed into the storm-water tank, the overflow being treated on a storm-water filter. The latter has only just been completed, and it is therefore impossible to say anything as to its efficiency.

Refuse Destructor.—Until October, 1900, the collection and disposal of house refuse was done under contract. Since that date the work has been performed by the direct employment of labor, and the refuse disposed of in a Meldrum's destructor erected at the sewage works. There are two cells, each connected with the old Cornish boilers (which had previously been stoked with coal), worked in duplicate. The average quantity of domestic refuse collected per week is about 68½ tons, but in addition to this the destructor deals with about 7 tons per week of trade refuse, which the tradesmen have to cart themselves. One cell only is worked at a time. This quantity of refuse is more than sufficient for raising steam to work the sewage pumping plant, and the council are therefore considering the advisability of building an electric light plant. The average quantity of sewage pumped per day is about 800,000 imperial gallons. The grate area of each cell is 33 square feet. The old chimney stack, which is 70 feet high and 2 feet 6 inches in diameter, is ample for the work it is called upon to perform, and no complaints have been received from residents in the neighborhood of the destructor. The cost of the works, including the inclined roadway and the slight alterations necessary to the old boiler-house, was $5,850. The cost of working of the destructor is about 27 cents per ton. The additional cost of stoking with refuse over the cost incurred when the boilers were stoked with coal is 7 cents per ton of refuse; but it must be noted that the destructor has done away with the previous consumption of coal, costing $1,700 per annum. The clinker produced, amounting to about 30 per cent. of weight of refuse destroyed, is at present being used in the formation of bacteria beds, and can therefore be reckoned as a valuable asset.

The work of collection is so arranged that the refuse is removed thrice weekly from every house, and so that this work will be finished before noon each day. The desirability of providing each house with a properly covered portable sanitary ash-bin, and thereby doing away with the varied assortment of receptacles now employed by the householder, is occupying the attention of the Sanitation Committee. The cost of house refuse collection is 61 cents per ton.

Municipal Depot.—A depot for the storage of materials, housing of horses and carts, etc., is being constructed at an estimated cost of $15,000. The new stables and depot are designed to accommodate seventeen horses. The width of the stables is 30 feet and the height 13 feet. The stalls are 7 feet in width, and will be paved with concrete. The cart sheds, of which there will be two, each 50 by 30 feet, will be covered with slate. The paving of the cart sheds will be of bricks on concrete. That portion of the depot through which the heavy traffic will pass will be paved with granite and the remaining area with tarred macadam.

Provision will be made for two steam rollers, cement store, tool-house, yard office, forge and workmen's mess-room, harness-room, general stores, and the usual conveniences. The caretaker's quarters will be at the entrance to the depot.

Electricity Supply Works.—The electricity supply works, for which Mr. Dennis acted as consulting engineer, were inaugurated in May, 1902; and so well has the public supported the undertaking, that there are eighty consumers connected, and the revenue is sufficient to cover all working expenses.

The engine house is 50x30 feet in plan, affording room for doubling the present engine power. The boiler house is 41x45 feet. The most interesting feature of the plant is the completeness of the installation considering the comparatively small amount of power generated. The engine house contains three Willans-Parker sets, each of 90 kilowatts capacity, which deliver current at 420 to 460 volts. The balancer and boosters are four Parker machines all coupled to the same shaft. The two boosters, for charging the two halves of the battery, are driven by either or both of the balancer armatures, the output of each being 40 amperes at from 10 to 100 volts. The output of each balancer armature is 40 amperes at 210 volts, capable of dealing with an out-of-balance current of 75 amperes on either side of the system. A storage battery of 244 cells, each of 11 plates and 300 ampere-hour capacity is provided. There are 12 cells of the same size, fitted up as a meter-testing battery and for charging small accumulators for motor-cars, etc.

The boiler house contains two Babcock & Wilcox boilers, each with a heating surface of 1,619 square feet, capable of evaporating 5,000 pounds of water per hour at a working pressure of 160 pounds per square inch. One pulsometer surface condenser, having 850 square feet of brass tube surface, is provided. There are two Worthington feed pumps, each capable of feeding two boilers when working at full capacity. A Baker's oil-extractor is inserted in the main exhaust pipe before it reaches the condenser. In the vertical exhaust pipe in the engine room is a Bailey's atmospheric balanced valve, which automatically opens the exhaust to atmosphere in case of the condenser failing. Outside of the boiler house there is a cooling pond, 40 by 80 feet by 4 feet 6 inches deep, for the condenser circulating water. The pond is connected to a system of surface-water drainage, which receives the water from house roofs and roadways of a residential part of the district. There is a connection from the pond to the hot well, to avoid as far as possible the use of town's water, which is very hard for boiler purposes. A Green economizer of 144 tubes is provided, the scrapers of which are driven by a Parker enclosed motor of 2 brake horse-power. The economizer was designed to deal with a boiler power much greater than that at present installed.

The average price for current obtained from private consumers has been practically 10 cents per kilowatt-hour. The eight arc lamps used for public lighting are charged at $77.90 per lamp per year, lighted till one A. M., and incandescent street lamps are charged at $13.20 per annum, lighted till 2.30 A. M. The total cost of the installation was about $97,500.

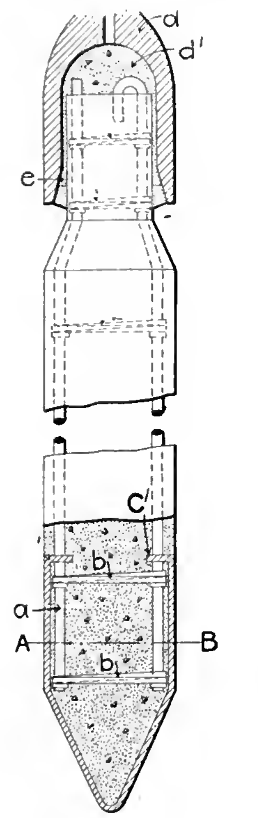
The current for electric lighting and power for the military camp is furnished by an entirely separate plant consisting of three sets of 250 kilowatts and one of 100 kilowatts capacity. In this lighting system there were about 14,000 points to be wired for, several points having from three to five lights each.

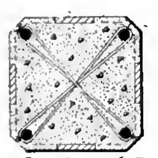
Cold Weather's Effect upon water consumption was shown in a marked way during a recent brief period of low temperature in the Boston metropolitan district. The total consumption for each day from December 7 to 13 is reported to have been respectively about 106,000,000, 125,000,000, 151,000,000, 145,000,000, 134,000,000 1[illegible],000,000 and 138,000,000 gallons, the maximum exceeding 150 gallons per capita. During November the daily consumption was about 102,000,000 gallons, equivalent to 116 gallons per capita.

Concrete Piles of the Hennebique System.

In a paper describing the Hennebique system of armored concrete construction presented to the Civil Engineers Club of Cleveland by Mr. Leopold Mensch, C. E., there is an interesting description of solid concrete-steel piles. They are made in moulds, and each contains four vertical rods a at the corners of the cross-section as shown in the accompanying drawings. The rods are stayed by loops or hooks b of large wire sprung into place across the sides of the pile and held transversely by horizontal strips of thin metal with their ends split and curled down to make stiff clamps.

The feet of the piles are either wedge-shape or pyramidal and are protected by cast iron points with side plates which bend in at c' to lock with the concrete. The upper ends of the





Section A-B.

piles are shouldered in to give clearance between them for the driving cap d. This is a cast steel hood which fits loosely around the neck of the pile, and is filled with a cushion of dry sand d' retained by a clay ring and hemp gasket e at the bottom of the cap. The sand absorbs the impact of the hammer so as to permit the piles to be driven safely, and it raises the hood sufficiently above the top of the pile to permit the reenforcement rods to extend beyond the concrete, if desired, for connection with the superstructure.

The sheet piles are similar in side elevation to the bearing piles except for the flat wedge-shaped points beveled on one side only in the usual manner. They are grooved on both the narrow faces with semi-circular slots o' o' extending to the shoe. On the long face there is a short tongue or tennon at the bottom of this slot which has a semi-circular projection beyond the face of the pile to engage the groove in the short face of the pile previously driven. When two piles are set up together, the adjacent grooves afford an opening to receive a pipe through which an hydraulic jet is operated to scour the earth around the point and facilitate the driving of the pile. The grooves on the short faces of the piles extend to the points and provide orifices for the discharge of the jet.

The jet pipe serves as a guide in driving, and after it is withdrawn the grooves are filled with grout which locks the piles together and makes water-tight joints. The piles are said to be rather more expensive than wooden ones; but are considered very satisfactory because of their immunity from decay and attacks of the teredo.

In connection with this European system, it is interesting to note that the Raymond Company have recently built the foundation of the new Carnegie library, Aurora, Ill., with vertical concrete foundation columns set in the earth so as to act like piles, but cast in place in permanent steel moulds previously driven into the ground. Conical steel shells 14 feet long, 13 inches in diameter at the bottom and 20 inches in diameter at the top were fitted with heavy collapsible steel cores and driven through a gravel and cinder fill with sometimes as many as 200 blows of a 2,400 pound hammer. The cores were removed and the steel shells rammed full of concrete. Trenches were dug around the piles, and the exposed upper portions of the shells being removed, the concrete wall of the superstructure was built to enclose, and be supported on, the tops of the piles.

Personal and Obituary Notes.

Mr. William J. Wintyen has been reappointed borough engineer of Doylestown, Pa.

Mr. A. Lincoln Walters has been appointed superintendent of streets, sewers and parks of Seattle, Wash.

Mr. A. M. Poynton has been promoted to principal assistant inspector of buildings of the District of Columbia.

Messrs. George W. Harrison, Frank P. Rice, W. S. Duncan and Samuel W. Wilkes have been elected water commissioners of Atlanta, Ga.

Mr. E. von der Osten has resigned as chief of the Engineering Department of the United States Garbage Reduction Co., of Lynn, Mass.

Mr. Dennison Fairchild, for the past six years division engineer at Buffalo of the Erie Railroad, has resigned, to resume private practice in that city.

Mr. John Flynn, Jr., has been appointed city engineer of Troy, N. Y., succeeding Mr. Edwin R. Cary, who was removed, it is understood, for political reasons.

Mr. Bleecher Ogden, formerly manager of the advertising department of the International Correspondence Schools, is now connected with the advertising department of the H. W. Johns-Manville Co., of New York.

Mr. James H. Fuertes, M. Am. Soc. C. E., consulting engineer for the Public Works Commission of Harrisburg, Pa., has been retained by the Steelton, Pa., water commissioners, to analyze the river water at Steelton.

Mr. Marshall N. Shoemaker has resigned his position with the American Bridge Co., in order to take charge of the Philadelphia office, in the Commonwealth Building, of the American Concrete-Steel Co., of Newark, of which he is vice-president.

Mr. E. Lawrence Corthell, M. Am. Soc. C. E., who recently returned from the Argentine Republic, where he was consulting engineer for the Ministry of Public Works, in the employ of Hall, Eddy & Cia., addressed the Boston Society of Civil Engineers December 17 on the prospects in that country.

Edward Hughes, a member of the contracting firm of Hughes Brothers & Bangs, of Syracuse, died suddenly in Buffalo, December 19. He was 45 years of age and succeeded to the business on the death of his father 30 years ago. Among the important contracts which have been awarded to the firm were the locks at Sault Ste. Marie, Mich.; the Delaware breakwater at Philadelphia, a breakwater in Narragansett Bay and the breakwater at Buffalo, which had called him to that city.

Mr. Frank Hedley, general superintendent of the Lake Street and Northwestern elevated railroads in Chicago, has been appointed general superintendent of the Interborough Rapid Transit Co., of New York, which has control of the surface, elevated and subway railways of that city. Though but 40 years of age, he has held a responsible position since 1894 in Chicago in elevated railway equipment and operation. Mr. Elzer C. Noe has been appointed to succeed him.

The following changes in railroad engineering positions have been reported: On the Pennsylvania Railroad, Mr. E. W. Atterbury has been appointed general manager and he is succeeded as general superintendent of motive power by Mr. A. W. Gibbs. Mr. G. W. Creighton has been appointed general superintendent at Altoona, and Mr. R. L. O'Donnell succeeds Mr. Creighton as general superintendent of the Buffalo & Allegheny Valley division. Mr. M. L. Byers, engineer of maintenance of way of the Baltimore & Ohio Railroad, has been appointed assistant to the general manager. Mr. D. D. Carothers has been appointed general superintendent of the Baltimore & Ohio Southwestern Railroad. Mr. A. B. Atwater, for the last three years assistant general superintendent of the Michigan Central Railroad, and previous to that engineer, has been appointed assistant to the second vice-president and general manager of the Grand Trunk Railway, of the lines west of the St. Clair River, with headquarters at Detroit.

Concrete Sidewalks to the extent of 27½ miles are reported have been laid in Toronto, Ont., during the year.

Faulty Ignition in Gas Engines is not always due to the ignition gear proper, according to a paper read by Mr. H. Mensforth before the Sheffield Society of Engineers and Metallurgists, April 28, 1902. One cause of late ignition, he claims, is the presence of water in the cylinder. He has found that oatmeal thrown in the tank supplying the jacket will cure some cases of leaking into the cylinder. Pre-ignition, he says, is often caused by some deposit in the cylinder becoming heated by the working of the cylinder. This is usually traceable to either tar in the gas, carbonization of the lubricating oil, or foreign matter in the air inlet pipe, and this, getting hot, he has found, will cause pre-ignition. Blast-furnace gas, often so poor that it will not burn under steam boilers, he has proved satisfactorily in gas engines by providing special ignition arrangements. The requirements are an exceedingly high temperature and an adequate area of well sustained igniting incandescence. Mixed gas and air under pressure allow any desired heat on the ignition tube to be obtained for the ignition with satisfactory results.

CONTRACTING NEWS

OF SPECIAL INTEREST TO

CONTRACTORS, BUILDERS, ENGINEERS AND MANUFACTURERS

OF ENGINEERING AND BUILDING SUPPLIES.

For Proposals see pages 21, 23, 24 and 36.

WATER.

Providence, R. I.—The Builders Iron Foundry, of Providence, have secured the contract for furnishing special casting, iron work for sewers, etc., bids for which were opened on Dec. 18.

Worcester, Mass.—John G. Brady, Water Comr., in his annual report is stated to have recommended a more complete metering of water used, and an extension of the low service system to relieve the high pressure service.

Long Island City, N. Y.—Bids are wanted Jan. 2 (extension of date) for furnishing, delivering and laying water mains in several streets in the Boro. of Queens. Robt. Grier Monroe, Water Comr., N. Y. City.

New York, N. Y.—The Bd. of Estimate on Dec. 19 appropriated $515,000 for improving the water supply system, of which $400,000 is for improvements in reservoirs and lands taken for the Manhattan and Bronx supply, $13,500 for improvements to pumping stations in Queens and $100,000 for remodeling and consolidating the present Gravesend and New Utrecht pumping station in Brooklyn.

Baltimore, Md.—The Water Bd. on Dec. 18 approved the specifications for meters. It also decided to increase the number of disc meters to be purchased with rotary meters.

Bids will be received Dec. 31 by the Bd. of Awards for furnishing and delivering to the Water Bd. such supplies as may be required during the year ending Dec. 31, 1903, including cement, lead-lined iron pipe, cast iron pipe and fittings, valves, etc. Alfred M. Quick, Water Engr.; Thos. G. Hayes, Pres. Bd. of Awards.

Paterson, N. J.—Bids were opened as follows, Dec. 22, for brick lining the Hook Met. tunnel, not including cement: Jas. B. Hall, Jersey City—8-in., $18.24 per ft.; 12-in., $21.24 per ft. G. H. Bouton, Jersey City—8-in., $10.58; 12-in., $13.52. Abbot-Gamble Constn. Co., Times Bldg., N. Y. City—8-in., $62.37; 12-in., $70.

Washington, D. C.—The District Comrs. are stated to have authorized the laying of 3,620 ft. of 12-in. water main from 28th St. and Bladensburg Road, at a cost of $5,750.

Punxsutowney, Pa.—The management of the Buffalo, Rochester & Pittsburg R. R. is reported to be considering the advisability of establishing water purifying plants at Butler Junction and Punxsutawney. J. M. Floesch, Ch. Engr., Rochester, N. Y.

Middletown, N. Y.—The Clerk of Bd. of Water Comrs. writes that it was voted Dec. 23 to issue $27,000 bonds to complete the water works.

South Brooklyn, O.—Bids will be received Jan. 12 by the Village Bd. of Water Wks. Trus. for laying water mains on several streets. Specifications and blanks can be had at the office of the Wm. H. Evers Engineering Co., 634-635 Williamson Bldg. W. T. Rupikofer, Village Clk.

Lansing, Ia.—N. A. Nelson, City Clk., writes that plans and specifications have been prepared for water works. Electric light plant will not be constructed for the present.

Lake Wilson, Minn.—It is reported that at a mass meeting here it was voted to construct water works.

Burlington, Ia.—Local press reports state the Citizens' Water Co. will probably make extensive improvements.

Centralia, Ill.—Bids will be received by the Water Com. Jan. 6 for furnishing material and laying 6-in. water mains on E. Bway. Address A. J. Sliger.

Wausau, Wis.—Prof. E. G. Smith, of Beloit College, employed to make an analysis of the water supply, is reported to have recommended a filtering plant, and estimates the cost at about $20,000.

Cuba, Wis.—This city is reported to have voted to erect a 2,000-bbl. steel tower and tank for the water works, at a cost of $4,100.

Boone, Ia.—City is prospecting for water in shallow veins, and expects to put in an auxiliary plant in the near future. Chas. E. Russell, City Engr.

Milwaukee, Wis.—Bids will be received Jan. 3 for constructing brick conduits on 2 avenues under the depressed tracks of the Chicago & North Western Ry. in 18th Ward for the reception of the large water mains of the city. Chas. J. Poetsch, Chmn. Comrs. of Pub. Wks.

Cincinnati, O.—Bids will be received Jan. 23 by the Bd. of Trus., "Comrs. of Water Wks.," for $1,000,000 water works bonds. August Herman, Pres.

Ashland, O.—An ordinance is reported to have been passed authorizing the issue of $8,000 bonds for improving the water system.

Kansas City, Mo.—Local press reports state that the Bd. of Pub. Wks. has under consideration the proposition of building a new water plant on the Clay County side of Missouri River. It contemplates the abandonment of the Quindaro and Turkey Creek pumping stations, and the construction of a high pressure line from the proposed new pumping station through a tunnel under Missouri River. The Supt. of Water Wks. will be required to furnish the Bd. with an estimate of cost of proposed improvement.

Liberty, Mo.—The Council is reported to be considering the issue of bonds for the construction of water works.

New Orleans, La.—The Council has passed an ordinance authorizing the New Orleans Water Works Co. to extend its water mains on Magazine St. and to erect 15 plugs along that street.

Obion, Tenn.—There is talk of constructing water works and an electric light plant, $8,200 having already been subscribed for this work. As soon as the town is permitted to do so by the Legislature, it will grant a 15-year franchise.

Springfield, Tenn.—Robt. L. Lund, Engr., of Nashville, writes in regard to bids opened on Dec. 15 for constructing water works and an electric light plant that the contract (with the exception of the cast iron pipe, tower and tank) was awarded to the Union Machine Co., of Nashville, for $17,600. The Chicago Bridge & Iron Co. secured the contract for the 80,000 gal. tank and tower, total height 134 ft. 6 in., for $6,400. Pipe furnishing and laying not yet awarded.

Laredo, Tex.—S. F. Wiles, of San Antonio, is reported interested in the construction of an irrigation plant in Laredo.

San Antonio, Tex.—The Acme Irrigation Co. has been incorporated, with a capital of $50,000, to irrigate a tract of 1,200 acres of land s. w. of San Antonio. It is also proposed to erect a cannery. J. B. Fears, of San Antonio, is Secy.

Austin, Tex.—A press report states that the Committee appointed by Governor Sayers to negotiate with the city of Austin for the purchase of the old plant of the water company, has reported recommending that the State construct its own plant and not buy the old plant from the city.

Eagle Lake, Tex.—N. S. Hunsdon, 503 E. 8th St., Austin, Pres. Colorado Agricultural Co., writes in regard to the construction of an irrigation system that it is proposed to expend about $3,000 this year. Machinery wanted now.

Paris, Ky.—N. Mitchell, Supt. Paris Water Co., writes that it is proposed to erect a filter plant in 1903. Wm. Wheeler, 14 Beacon St., Boston, Mass., is the Engineer.

Birmingham, Ala.—A resolution has been presented in Council to the effect that the Mayor appoint a committee to consider and make a report on the question as to the best way and means of securing a water system for the city.

South McAlester, Ind. Ter.—Contracts will be let about Jan. 12 for the construction of water works and a sewerage system, estimated to cost $160,000. Engineer, Chester B. Davis, 10 Wall St., New York, N. Y., and San Antonio, Tex.

Bisbee, Ariz.—It is stated that the Bisbee West Mining Co. will probably begin the construction of water works to supply this city, early in the coming year.

Havre, Mont.—The Town Clk. writes that the date of receiving bids for the construction of water works and an electric light plant has been extended to Jan. 30.

Pueblo, Colo.—The Trus. of the North Side Water Works are stated to have decided to construct a new standpipe north of Fairmount Park.

Gillette, Colo.—Geo. Atherton, Chas. Gillett, and others are reported to have located the waters of north Oil Creek at Waters Station. They intend building a reservoir and using the Horse Thief Park as a storage basin.

Greeley, Colo.—The City Council is stated to have voted to purchase water rights on the Big Thompson, the water to be brought to Greeley for domestic purposes.

Evans, Colo.—Bids are wanted Jan. 20 for constructing the outlet ditch of the Union Reservoir Co., including head gates. Jas. L. McCain, Secy.

Wessington Springs, S. D.—Bids will be received Jan. 5 by Geo. R. Bateman, Town Clk., for sinking an artesian well.

Caldwell, Idaho.—Faris & Kesl, of Boise, are stated to have secured the contract for work on the Phyllis Canal for the Pioneer Irrigation District for $65,000.

Riverside, Cal.—The Jurupa Heights Water Co. has been incorporated, with a capital of $500,000, by W. E. Pedley, F. D. Hudson, and others, all of Riverside.

Julesbury, Colo.—Bids will be received Jan. 1 by the South Side Irrigation Co. for constructing a tunnel 300 ft. in length on the ditch of the company. P. D. Goss, Secy.

Weiser, Idaho.—The Weiser Irrigation District is stated to have sold bonds to the amount of $60,000. It is reported that contracts will shortly be let for the enlargement of the ditch.

Claremont, Cal.—The Citizens' Light & Water Co., of Claremont, has been incorporated, with capital of $75,000. Directors: L. T. Gillet, G. A. Gates, C. C. Johnson, and others, all of Claremont.

Hawkesbury, Ont.—A press report states that Thos. McLaughlin, of Ottawa, has secured the contract for constructing water works and a sewerage system, for about $70,000.

Woodstock, Ont.—The Town Council is reported to be considering the question of water works.

Marieville, Que.—V. H. Dupont, 35 James St., Montreal, Engineer for Marieville, writes that John F. Connolly, Toronto, will receive the contract for constructing water works, his bid (opened Dec. 22) being $32,900. Other bids were as follows: H. Hubert, Marieville, $40,769; Henault & Heffermann, Montreal, $38,677; P. Denis & S. Sinical, St. Cesaire, Que., $38,925.

SEWERAGE AND SEWAGE DISPOSAL.

Fairhaven, Vt.—It is proposed to construct sewers for the village, at a probable cost of $30,000. W. H. Preston, Town Clk.

Corinth, N. Y.—Surveyor Mott is reported to have estimated the cost of a sewerage system between $17,000 and $20,000. A vote on the question will probably be taken some time in January.

Fishkill Landing, N. Y.—The citizens are stated to have voted Dec. 18 to appropriate $30,000 additional for the completion of the sewerage system.

Bradley Beach, N. J.—The W. J. McCloud Construction Co., of Elizabeth, is stated to have secured the contract for constructing the sewerage system, for $20,803.

Reading, Pa.—It is stated that Mayor Yeager will probably soon sign the ordinance to set aside $30,000 out of next year's revenue to extend the intercepting storm water sewer to its planned completion.

Abington, Pa.—Cheltenham Township Comrs. are reported to be considering an ordinance for a general sewer system to extend over into Abington.

Penn Yan, N. Y.—The citizens are stated to have voted to expend $500 to secure the services of an engineer to draw plans for a system of sewers and the disposal of sewage.

New York, N. Y.—The following bids were opened Dec. 23 by Boro. Pres. J. A. Cantor for extension of outlet sewer at the ft. of W. 72d St.:

Main items.	Wm. J. Moore.	N. Y. Sewer Const. Co.	F. Thilemann, Jr.
4-ft. wooden barrel sewer, 371 ft...	$40	$29	$41
4-ft. brick sewer, 79 ft...........	25	35	51

Philadelphia, Pa.—The Fin. Com. of Council is stated to have made the following recommendations: $100,000 for the Market St. sewer, $200,000 to complete the Aramingo sewer system, to the Bureau of Highways $100,000 for repairing, altering and extending sewers and inlets, and to the Bureau of Surveys $60,000 for branch sewers and inlets; $100,000 for main sewers, $100,000 for the McKean St. relief sewer and $100,000 for the Cobocksink relief sewer.

Schenectady, N. Y.—The City Council is stated to have passed a resolution providing for an increased expenditure of $125,000 for sewers.

Hazelton, Pa.—City Engr. Cellax estimates the cost to arch Mill Creek at $8,574. He also estimates the cost of paving Wyoming St., 5,885 sq. yds., as follows: Brick, $12,359; Bituminous macadam, $13,241, and sheet asphalt, $14,124.

Brooklyn, N. Y.—The Bd. of Estimate is reported to have granted $749,000 for the completion of the Foster Ave. sewer.

Belleville, Ill.—G. W. Beinecke, City Clk., writes that it is proposed to construct a sewer in W. Main St., at a cost of $14,000. Louis Graner, Engr. in Charge.

St. Paul, Minn.—A press report states that $250,000 will be expended next year for sewers, and $300,000 for paving.

Cedar Falls, Ia.—The City Council is reported to have divided the city into sewer districts, which is the beginning of a very extensive system, which will be established and added to as the city grows. At present there is no sewer system. Several sewers are in existence, but each is perfect in itself and are not all connected. The plan now outlined provides for a sewer system costing between $100,000 and $200,000.

Grand Rapids, Mich.—A press report states that Alderman Hilton has a plan for a system of sewers at the base of the hill bluffs running from East Bridge St. to Coldbrook St. They are to be storm water overflow sewers, 7 of them, and not connected in any way.

Rockford, Ill.—The Com. of Sewers is stated to have decided to ask for an appropriation of $14,000 for sewer building. One-half of this is to be expended on the east side and an equal amount on the west side of the river.

Ft. Scott, Kan.—Contracts will soon be let for a sewer, and 22 blocks of brick paving. U. S. Stoner, City Engr.

South McAlester, Ind. Ter.—See "Water."

Beaumont, Tex.—Bids will be received Jan. 6 by Thos. H. Langham, Mayor, for the following bonds, $75,000 for sewerage, $75,000 school, $95,000 paving and $40,000 for city hall.

Moscow, Idaho.—The City Council is reported to be considering the construction of a sewerage system, and have asked Otto Welle, of Spokane, Wash., to visit the city and prepare estimates, etc.

Portland, Ore.—Local press reports state that the following bids were opened Dec. 16 by the Bd. of Pub. Wks. for the Cook Ave. sewer: John Kiernan, $82,303; Jacobsen-Bade Co., $81,100; Frsiney, Sweeney & Keating, $77,960, and J. B. Slemmons, 348 Yamhill St., $69,838.

Hawkesbury, Ont.—See "Water."

BRIDGES.

Providence, R. I.—A resolution has been passed by the City Council authorizing the issue of $120,000 for building the bridge and retaining walls in the rear of the site for a Post Office on Exchange Place.

Fall River, Mass.—The building of a bridge between Fall River and Somerset is again reported to be under consideration.

Boston, Mass.—The Cambridge Bridge Comn. is reported to have voted to annul the contract made last April with the Cape Ann Granite Co. for furnishing cut stone for the 2 central piers of the new bridge, and have also voted, according to reports, to award said contract to the Rockport Granite Co.

Greenfield, Mass.—An agreement is reported to have been reached between the Grade Crossing Comrs. and the officials of the Boston & Maine R. R. to do away with the grade crossing at Sprout's Crossing, in South Deerfield, by building a bridge, estimated to cost $25,000.

Essex, Mass.—It is stated that a steel bridge is to replace wooden structure at Main St.

New York, N. Y.—Comr. Lindenthal is reported to have instructed the engineers to prepare plans for the Blackwell's Island Bridge according to the suggestions made by the Mayor's Special Comn. The plan is to have a bridge 91 ft. wide.

Newtown, Pa.—The Co. Comrs. have awarded, according to press reports, the contract for building a bridge at Jefferson Ave., Newtown, to the Wynkoop-Breley Co., for $6,590.

Baltimore, Md.—Local press reports state that a bridge is to be built across the middle branch of the Patapsco River at Spring Garden by the Wabash R. R. Co.

Philadelphia, Pa.—The Finance Com. of Councils on Dec. 18 made the following recommendations: To the Bureau of Highways, $15,000 for general repairs to bridges, and to the Bureau of Surveys, $150,000 for new bridges and $20,000 for the reconstruction of bridges over Poquessing Creek, on the line of Frankford Ave.

Trenton, N. J.—It is stated that the building of a bridge across the Canal connecting the plants of the Trenton Fire Clay & Porcelain Co. and the Mott Iron Co. is being considered.

Lewisburg, Pa.—The Comrs. of Northumberland & Union Counties have petitioned the State Bd. of Property, at Harrisburg, to construct a bridge across Susquehanna River at Lewisburg.

Pine Grove, Pa.—The Comrs. appointed by Dauphin Co. Court have recommended by the State the building of a steel bridge across Schuylkill River, near Auburn, to cost about $10,000.

Allegheny, Pa.—An ordinance has been passed by the Select Council authorizing the Western Bridge Co. to construct and maintain a bridge across Ohio River from Wilkins St. to McKees Rocks.

McKees Rocks, Pa.—The Boro. Council has voted to build a bridge across Chartiers Creek, at Singer Ave.

Utica, N. Y.—The lowest bid received for building a culvert on Welsh Bush Road is reported to have been submitted by the Dwyer Construction Co. at $5,420.

Erie, Pa.—An ordinance has passed 3d reading in the City Councils authorizing the issue of $15,000 bonds as the city's portion of the cost of overhead crossing on Buffalo Road.

Jacksonville, Fla.—The Bd. Pub. Wks. has received from the Jacksonville Electric Co., with their approval, plans for a viaduct to be built in this city.

Berkley, Va.—The Bd. of Superv. intend building, at a cost of about $5,000, a steel bridge across Pascara Creek at Maple Ave.

Bay City, Mich.—The Bay County Bridge Comn. is contemplating the substitution of steel for the present wooden floor systems of the Cass and Lafayette Ave. bridges, and also other changes. Each bridge is about 650 ft. long. Blomshield & McCloy, of Bay City, are the Consulting Engineers.

Port Huron, Mich.—Mayor-elect Graves is reported to be in favor of building a cantilever bridge at Military St.

Milwaukee, Wis.—The Board of Pub. Debt Comrs. have approved the bond issue of $150,000 for a bridge to Jones Island. The bonds, according to local press reports, will be sold early in January.

Fairmount, W. Va.—The building of a bridge across Monongahela River, to replace present structure at Washington St., is reported to be under consideration.

Youngstown, O.—Press reports state that the United States Steel Co. has accepted plans for a viaduct to be built by the Steel Co. across Mahoning River.

Columbus, O.—The South Side Business Improv. Assoc. is reported to be interested in the building of a viaduct at South High St.

Chicago, Ill.—The following bids for the substructure of the North Western Ave. bridge were received by F. W. Blocki, Comr. of Pub. Wks., Dec. 15: Fitzsimmons & Connell, $80,273; Lydon & Drews, $87,065; Jackson & Corbett, $92,767.

Steubenville, O.—The bridge which it is proposed to build across Ohio River at Market St. will cost, according to press reports, about $300,000.

Cincinnati, O.—The question of issuing $175,000 bonds for the purpose of constructing the Grandin Road viaduct is reported to be under consideration.

The Bd. Pub. Service has instructed Engr. Stanley to prepare plans and specifications and estimate of cost of a viaduct to be built from Fourth and Pike Sts. to Mt. Adams.

St. Paul, Minn.—The building of a bridge from Jackson to Eaton Sts. is being agitated.

Duluth, Minn.—The City Engr. is preparing estimates of the cost of replacing about 35 bridges in the 8th Ward, which are said to be worn out.

Oshkosh, Wis.—The City Council is stated to have adopted plans prepared by Erickson & Lehman, of Chicago, for a $6,000 bridge to be built across Sawyer Creek, and bids will be received by the Bd. of Pub. Wks. Jan. 5.

Milwaukee, Wis.—It is reported that the Com. on Bridges has rejected the bid of the Milwaukee Steel Structural Co. for the Muskegon Ave. bridge. The price was reported to be $93,800.

A resolution has been passed by the Common Council calling for bids for a bascule bridge to be built at West Water St.

Chicago, Ill.—Local press reports state that the Jackson & Corbett Co. submitted to the Drainage Bd. the only bid for the superstructure of the proposed new bascule bridge at Harrison St., at $159,000.

Mt. Carroll, Ill.—It is stated that the proposition to issue $3,000 bonds to build a bridge in Elkhorn Grove Townships, Carroll Co., carried at the recent election.

Ashland, Wis.—The Bd. of Pub. Wks. has, according to reports, authorized the rebuilding of St. Clair St. bridge.

Newton, Ia.—Bids will be received Jan. 5 by the Co. Bd. of Superv. for furnishing bridge material for the ensuing year. Joe Horn, Co. Aud.

Brookfield, Mo.—L. F. Goodale, of St. Louis, Ch. Engr. Hannibal & St. Joseph R. R. Co., writes that it is proposed to rebuild the steel bridge over Yellow Creek which recently collapsed.

Lake Charles, La.—The Police Jury is reported to be preparing to let the contract for building a 124-ft. steel span bridge across English Bayou.

Arkadelphia, Ark.—M. C. Hasselle, Chattanooga, Tenn., has submitted to the Co. Comrs. plans and specifications for a steel bridge to be built across Ouachita River, this city, at a cost of $25,000.

San Antonio, Tex.—The City Council has passed an ordinance requiring the Southern Pacific R. R. to build a viaduct at Walnut St.

White Eagle, Okla. Ter.—See "Government Work."

Stockton, Cal.—Bids will be received Jan. 6 by W. B. Hamilton, Clk. of Bd. of Superv. of Sacramento Co., at Sacramento, for constructing a joint steel drawbridge over the Mokelumne River, between Sacramento and San Joaquin Counties, at Miller's Ferry.

Spokane, Wash.—Local press reports state that the City Comrs. will soon ask for bids for improving the south end of Monroe St. bridge, for the filling in and extending of Main Ave. to the bridge, which has been roughly estimated by City Engr. A. F. Gill at $30,000. The plans call for the tearing out of the south end of the bridge, the building of a new stone pier and the construction of a 10-ft. steel girder span extending over the road into Peaceful valley and the moving of the present 50-ft. steel span over the road to the extreme south end of the bridge.

PAVING AND ROADMAKING.

Gloucester, Mass.—The City Council has passed an order to issue $50,000 bonds for the layout and extension of Rogers St.

Bridgeport, Conn.—City Engr. Scofield estimates the cost of paving East Main St. at $10,425 and Broad St. at $13,750.

Springfield, Mass.—The Common Council has approved of the issue of $125,000 bonds to be used for the Court Square extension.

Philadelphia, Pa.—The Fin. Com. of Council has made the following recommendations: To the Bur. of Highways, $75,000 for paving intersections of streets in front of unassessable property, $150,000 for repairs to paved streets, $250,000 for repaving and maintaining unpaved and gravel streets, $100,000 for surfacing and resurfacing roads and streets, and $50,000 for repairs to asphalt streets.

The Select Council has passed an ordinance making 21st St. a Fairmount Park driveway, and authorizing the removal of car tracks from it.

The Council on Dec. 22 passed ordinances providing for a $2,500,000 driveway from Torresdale to Broad and Cayuga Sts., and apropriating $80,000 to repave streets with improved pavements, not occupied by passenger railways.

Somerville, N. J.—The Somerset Co. Bd. of Chosen Freeholders has, according to local press reports, awarded to Richards & Gaston, of Raritan, the contract to macadamize the road from Woods Tavern to Neshanic Station, for $36,509.

New York, N. Y.—The following bids were opened Dec. 23 by J. A. Cantor, Boro. Pres., for repaving with asphalt on present pavement relaid as foundation, 23d St., from 6th to 10th Aves.—A, Barber Asphalt Paving Co.; B, Uvalde Asphalt Paving Co.; C, Continental Asphalt Paving Co.; D, Sicilian Asphalt Paving Co.:

Bidders.	Asph., 14,220 sq. yds.	Relay, 11,560 sq. yds.	Concrete 360 cu. yds.	New curb, 6,200 ft.	Old curb, 350 ft.	Manhole covers, 26.
A........	$2.56	$0.45	$4.95	$0.82	$0.38	$20.00
B........	1.85	.42	6.00	.85	.35	20.00
C........	1.20	.36	5.00	.72	.30	21.00
D........	1.10	.30	5.00	.80	.30	17.00

St. George, S. I.—The Local Bd. of Pub. Improv. has been petitioned to regulate, grade, and pave with brick on portions of numerous streets, estimated to cost in all $218,000.

Binghamton, N. Y.—The macadamizing of a portion of Front St. is being considered.

Rochester, N. Y.—The Park Bd. is said to be considering the building of a boulevard on the west bank of the river.

Ithaca, N. Y.—The Bd. of Superv. has made an appropriation of $18,000 to macadamize Catskill turnpike under the provisions of the Higbie-Armstrong act.

Harrisburg, Pa.—Local press reports state that the contract for paving with sheet asphalt and curbing with granite on Market St. has been awarded to the Barber Asphalt Paving Co. at $1.98 per sq. yd. for paving, $1.23 per lin. ft. for curbing, and 25 cts. per lin. ft. for resetting curb. About 1,375 sq. yds. of pavement is to be laid and 1,530 lin. ft. of new curbing.

Allegheny, Pa.—The Select Council has passed the following resolutions: Submitting to a vote the question of increasing the city's indebtedness $7,490 for the grading, paving and curbing of Drum St.; authorizing the issuing of $15,527 bonds for the grading and paving of Woodland Ave., and $8,242 for a like improvement of Norwood Ave.

Pittsburg, Pa.—The Bds. of Select and Common Councils have passed ordinances authorizing the grading, paving and curbing of Homer St., from Negley to Haights Aves., estimated to cost $8,500, and the grading, paving and curbing of Breedshill St., from Winebiddle to Pacific Aves., estimated to cost $12,800.

Hazelton, Pa.—See "Sewerage and Sewage Disposal."

Brooklyn, N. Y.—The following bids were opened Dec. 24 by J. Edw. Swanstrom, Boro. Pres., for asphalt pavt. on Hinsdale St. from Atlantic to Sutter Aves.: 7,825 sq. yds. asphalt, Uvalde Asph. Pavg. Co., $1.60; Cranford Co., $1.30. 1,090 cu. yds. concrete, Uvalde, $5, and Cranford, $5. 18 manhole covers, Uvalde, $4, and Cranford, $5.

Charlottesville, Va.—Local press reports state that the question of issuing $80,000 street improvement bonds voted upon Dec. 17 resulted in favor of said issue.

Lynchburg, Va.—Press reports state that the Co. Comrs. intend purchasing a road roller.

Wilmington, N. C.—The Bd. of Audit & Finance has concurred in the appropriation of $20,000 made by the Bd. of Aldermen for the permanent improvement of streets, with the understanding that all material necessary for the improvement must be contracted for.

Portsmouth, Va.—City Engr. Bascom Sykes writes that the following bids were opened Dec. 22 for paving: For sheet asphalt with 7,000 ft. 4-in. curb, 3,500 sq. yds. granite block, 41,300 sq. yds. asphalt and repairs per sq. yd. for 5 yrs.: Cleveland Trinidad Pav. Co., Cleveland, 56 cts., $2.51, $2.18 and $3.00 respectively; total, $102,739. Southern Pavg. & Constn. Co., Chattanooga, 46 cts., $1.96, $1.92 and $2.25; total, $89,376. Warren Bros. Co., New York, 49 cts., $1.97, $1.93 and $1.93; total, $90,034. For 41,300 sq. yds. vitrified brick, Frank Pidgeon, Saugerties, 60 cts., $2.50, $2.45 and $4; total, $114,135. Va.-Carolina Constn. Co., Norfolk, 55 cts., $1.69, $2.31 and $2.31; total, $105,168. Cranford Pavg. Co., Washington, 75 cts., $2.60, $2.99 and $3.50; total, $137,837. Patterson & Briesen, Baltimore, 50 cts., $1.97, $2.53 and 15 cts.; total, $114,884. For bituminous macadam, Warren Bros. Co., N. Y. City, 49 cts., $1.97, $2.03 and $2.03; total, $94,164. Granite block: Southern Pavg. & Constn. Co., $1.97; total, $88,256. Va.-Carolina Constn. Co., $1.69; total, $75,712. Cranford Pavg. Co., $2.69; total, $120,512. Patterson & Briesen, $1.93; total, $86,464.

St. Paul, Minn.—See "Sewerage and Sewage Disposal."

Marinette, Wis.—The Bd. Pub. Wks. is reported to be preparing plans for macadamizing portions of several streets and for paving with brick on a portion of Vine St.

Lansing, Mich.—City Engr. Collar estimates the cost of paving with brick on Michigan Ave., from the Michigan Central Ry. to east line of Pennsylvania Ave., at $13,518.

Ft. Dodge, Ia.—The Barber Asphalt Paving Co., Chicago, has been awarded the contract for 29,836 sq. yds. asphalt paving at $1.99 and 16,628 ft. combined curb and gutter at 75 cts., total $71,053. The Standard Pavg. Co., Chicago, bid $2.15 on asphalt and 76 cts. on curb and gutter, total $76,828.

Lafayette, Ind.—Bids will be received by the Tippecanoe Co. Comrs. until Feb. 14 for paving the Main St. levee with sheet asphalt, cement sidewalk and cement curb and gutter. Estimated quantity, 6,800 sq. yds. pavement, 2,500 lin. ft. curb and gutter and 14,000 sq. ft. cement walk.

Sioux City, Ia.—The City Council will order 34,000 lin. ft. of paving to be done in 1903; 24,000 ft. will probably be asphalt, 10,000 lin. ft. brick. J. M. Lewis, City Engr.

Washington, Ia.—Local press reports state that the City Clerk will receive bids Jan. 15 for paving, with brick, on 12 blocks in the business portion of the city.

Menasha, Wis.—Local press reports state that John O. Jones, of Racine, submitted the lowest bid for paving Church St. at $6,684.

Saginaw, Mich.—Resolutions have been adopted by the Common Council to instruct the City Engr. to prepare plans, specifications and estimates of the cost of paving, with waterproof bituminous macadam, a width of 20 ft., on 3d St., and brick gutter on each side, 3 ft. wide, on a 6-in. concrete foundation, also for paving a width of 38 ft. in the center of Ames St. with similar macadam, and a brick gutter on each side 5 ft. wide, laid in a 6-in. concrete foundation.
The Pavement & Sewers Com. has decided to recommend the paving of Holland Ave., 30 ft. wide, with bituminous macadam, with brick gutters and cement curbs.

St. Joseph, Mo.—Resolutions have been passed by the Municipal Assembly for paving a portion of Jones St. with brick and for remacadamizing a portion of 15th St.

Lima, O.—The City Council has adopted resolutions for the grading, draining, curbing and paving with sheet asphalt portions of Cole St. and Lakewood Ave., also a portion of Jameson Ave., with vitrified brick.

Crookston, Minn.—Mayor Hitchcock has signed the contract with the Barber Asphalt Co. for paving with asphalt the business streets of the city. Estimated cost, $60,000.

Faribault, Minn.—It is stated that the City Council has decided to pave the streets in the business section of the city next season.

Milwaukee, Wis.—The Common Council has passed a resolution to issue $200,000 street improvement bonds.

Toledo, O.—Bids will be received Jan. 19 by Chas. H. Nauts, City Clk., for furnishing material and improving portions of 11th St. by paving with block on a concrete foundation or with asphalt block on the present sand foundation.

Cleveland, O.—The City Council has adopted resolutions to grade, curb and pave with asphalt on a 6-in. concrete foundation a portion of Crawford Pl. and to improve, similarly, portions of numerous streets, paving with brick.

Nevada, Mo.—The City Council has ordered resolutions drafted for paving Cherry St. with vitrified brick or asphalt, about 30,000 yds. J. M. Clack, City Engr.

Seattle, Wash.—The Bd. Park Comrs. and the City Engr. are considering the building of a system of boulevards, embracing about 50 miles.

Ft. Collins, Colo.—Bids will be received Jan. 15 by the Co. Comrs. for constructing about 20 miles of road for Larimer Co. John E. Ramer, Co. Clk.

Woodstock, Ont.—The City Council has adopted a resolution to pave with vitrified brick on Dundas St., at an estimated cost of $21,000.

POWER PLANTS, GAS AND ELECTRICITY.

Montague, Mass.—The State Gas & Electric Light Comn. is reported to have received a petition from the Dirs. of the Montague Electric Light & Power Co. for approval of an issue of stock to the amount of $20,000, to be used in establishing an electric light and power plant for private and public use within the town.

Boston, Mass.—The School House Com. have under consideration the following bids for installing electric work in the school to be erected on Norman St., West End: Edwin C. Lewis, $13,488; Erickson Equipment Co., $16,983; Jas. Wilkinson & Co., $13,491; Thos. W. Byrne, $14,450; D. Ross & Co., $12,309; Clark & Mills, $11,664; Lord Electric Co., $13,421.

Kent Furance, Conn.—A press report states that the New Milford Power Co. has been incorporated, with a capital of $1,000,000, to construct a dam across the Housatonic River at Kent Furnace, and another at the Great Falls, Falls Village.

Hammonton, N. J.—W. S. Graham, of Philadelphia, Pa., and Chas. E. Starr, of Camden, are stated to have petitioned the Council for a franchise to lay 5 miles of gas mains in the town. They propose to build a plant to cost $30,000.

Edwardsville, Pa.—The Boro. Council is stated to have granted a franchise to the Shawnee Electric Light Co., of Plymouth.

Utica, N. Y.—The Ways & Means Com. of the Bd. of Superv. is stated to have presented to the Bd. a resolution appropriating $10,000 for a new power house and boilers at the County House.

Philadelphia, Pa.—The Fin. Com. of Councils has recommended an appropriation of $309,891 for lighting with naphtha and Welsbach lamps.

Patchogue, L. I., N. Y.—The Town Bd. is stated to have granted on Dec. 20 a franchise to the Patchogue Gas Co.

Philadelphia, Pa.—The Select Council has passed an ordinance granting the Philadelphia Electric Co. permission to construct, acquire, maintain and operate a system of electric lighting, heat and power.

Glens Falls, N. Y.—A press report states that the Hudson River Water Power Co., which is building a dam at Spier Falls, has voted to increase its capital from $2,000,000 to $5,000,000. The increase will be used principally in constructing 2 more dams. One will be on Hudson River, 6 miles above the Spier Falls dam; the other on Sacandaga River, near Conklingville.

Erie, Pa.—The Erie Gas Co. is stated to have secured the contract for lighting 519 gas lamps for 5 yrs., at $18.75 per lamp per yr.

York, Pa.—An ordinance has been introduced in Select Council granting to the People's Steam Htg. Co. the right and privilege of laying pipes in the city.

Canandaigua, N. Y.—The Village Bd. is stated to have granted a franchise to the Lima Gas Co.

Portsmouth, Va.—An ordinance is stated to have been introduced in Council providing that the Com. on Finance & Lights and the City Engr. be authorized to look into the feasibility of the city constructing an electric plant or acquiring one of those already in operation here.

Hamlet, N. C.—A charter is stated to have been granted to the Hamlet Electric Light Co., with a capital of $100,000, to construct an electric light plant. Incorporators: Geo. O. Sanders, F. C. Allen, and others.

Appleton, Wis.—A press report states that O'Keefe & Orbison, of Appleton, are preparing plans for a water power improvement on Clinch River in Western Virginia for a company of Cleveland capitalists, who will erect a barytes mill with a capacity of 100 tons a day. The plans include a concrete dam, which will develop about 1,800 H.-P.

Lansing, Ia.—See "Water."

Brazil, Ind.—The Putnam Electric Co. has been incorporated, with a capital of $25,000, to construct and operate plants to furnish heat, light and power in Putnam County. John G. Bryson and Jas. N. Halstead, of Brazil, are among the incorporators.

St. Paul, Minn.—The Bd. of Aldermen and Assembly on Dec. 18 voted to award the contract for supplying gas for street lighting next year to the St. Paul Gaslight Co., at $16 a post, and for furnishing the lamps and caring for them to the Cleveland Vapor Light Co., at $10.50 a post.
The St. Paul Gaslight Co. is also reported to have secured the contract for lighting the city with electricity during next year.

Cleveland, O.—The only bid submitted Dec. 23 for furnishing, lighting, extinguishing and keeping in repair electric lamps, for 1 year, was from the Cleveland Electric Illuminating Co. for 450 watts overhead service, $77.88, and 450 watts underground service, $92.76.

Crystal Falls, Mich.—Bids will be received by the Bd. Pub. Wks. until Jan. 10 for 2 generators, etc., as advertised in The Engineering Record.

Grand Rapids, Wis.—A press report states that the Consolidated Water Power & Paper Co. announce that they will harness up the water power at this point of Wisconsin River the coming spring and summer. They will construct a dam 1,700 ft. long, 40 ft. wide at the base and 12 ft. at the top and will develop 7,000 H.-P., half of which will be used by the company for its paper mill and the remainder to develop electrical power for rent. It is estimated that $500,000 will be spent on the improvements. J. C. Jacobson is now preparing plans and will supervise the construction.

Detroit, Minn.—E. J. Bestick, Recorder, writes that the citizens voted on Dec. 17 to issue $14,000 bonds for the purchase of the electric light plant.

Cincinnati, O.—Bids are wanted Jan. 5 for improving Grandview Ave. by grading, curbing and macadamizing the roadway; also on Jan. 19 for improving Westwood Ave. in a similar manner, paving the roadway with brick and constructing the necessary drains. Robert Allison, Pres. Bd. Pub. Service.

Freeport, Ill.—Petitions have been presented to the Bd. of Local Improv. for 60,000 sq. yds. of macadam and 30,000 lin. ft. cement curb and gutter. G. W. Graham, City Engr.

St. Louis, Mo.—Contracts are stated to have been awarded on Dec. 12 as follows by the Bd. of Pub. Improv.: In the City Hall, for elevators to the Otis Elevator Co., $11,116; for the lighting apparatus to the Westinghouse Electrical Mfg. Co., $12,750, and for engines to the Chase Engine Mfg. Co., $13,453; at the Insane Asylum, for electrical apparatus, the Frank Adams Electrical Co., $5,689, and for engines to Brownell & Co., of Dayton, O., $3,330.

Danville, Ky.—A. T. Maltby, of Chicago, Ill., is reported to be here for the purpose of estimating the cost of a municipal electric plant. The citizens will soon vote on the issue of bonds for same.

Kansas City, Mo.—The Kansas City Electric Light Co. is stated to have secured the contract for lighting the city with arc lights of 2,000 c. p. at $65 per light per yr.

Norman, Okla. Ter.—The Norman Lighting Co. is reported incorporated, with a capital of $15,000, by Jas. Chenoweth, of Oklahoma City, and Henry Ulen, Jr., and Saml. Perratt, of Indianapolis, Ind.

Newkirk, Okla. Ter.—The City Council is stated to have granted the Newkirk Gas & Mineral Co. a franchise to construct and operate a gas plant.

Kaufmann, Tex.—The Kaufmann Electric Light Co., of Kaufmann, has been incorporated, with a capital of $25,000. Incorporators: M. A. Joy, S. E. Noble and W. S. Catlin.

Terrell, Tex.—The Terrell Electric Light Co., of Terrell, has been incorporated; capital, $25,000. Incorporators: S. E. Noble, M. M. Raley and M. A. Joy.

Lexington, Ky.—H. T. Duncan, Mayor, writes that the only bid received Dec. 23 for lighting the streets by electricity for 5 years was from the Lexington St. Ry. Co. at $78.50 per light per yr. for all night lighting.

Lewisburg, Tenn.—The citizens are reported to have voted Dec. 17 to issue $5,000 bonds to purchase an electric light plant.

St. Joseph, Mo.—An ordinance has been introduced in Council to grant a franchise to John I. Zeidler, John I. Rinaker, Jr., and John Murphy to operate a hot water heating and electric lighting plant here.

Aberdeen, S. D.—It is reported that the Aberdeen Gas Co. contemplates the purchase of a new electric light plant, to cost $30,000, if granted a new franchise.

Havre, Mont.—See "Water."

Beaumont, Tex.—See "Sewerage and Sewage Disposal."

Owen Sound, Ont.—Bids will be received Dec. 29 by A. J. Spencer, Town Treas., for $39,000 bonds, proceeds to be used for extending gas light plant; also $36,000 bonds for extending electric light plant.

ELECTRIC RAILWAYS.

Weston, Mass.—The Selectmen are stated to have granted the Newton St. Ry. Co. a franchise to construct a line over North Ave. from Waltham to Lincoln, a distance of about 2½ miles.

Methuen, Mass.—The Lawrence & Methuen St. Ry. Co. is stated to have purchased a site on the Howe road in Methuen, on which a power house will be constructed.

Manchester, N. H.—The Aldermen have granted permission to the Manchester St. R. R. to extend its tracks in various parts of the city and make other improvements. J. Brodie Smith, Mgr.

Taunton, Mass.—The Taunton, Assonet & Fall River Electric Ry. Co. has been recommended a franchise to run its cars to the east side of Taunton River, the line to be built in 11 months.

Sandwich, Mass.—The Sandwich, Hyannis & Chatham St. Ry. Co. has been incorporated to extend the Middleboro, Wareham & Buzzard's Bay Ry. into the heart of Cape Cod. The new line will be 45 miles long, extending from Sandwich station to a point near the Chatham light. Directors: Horace B. Parker, of Newton; Fletcher Clark, of Sandwich, and others.

Sandisfield, Mass.—The Selectmen are stated to have granted a franchise to the Winsted-Lee Trolley Co.

Littleton, Mass.—The Town Trus. are stated to have granted a franchise to the Lowell & Fitchburg St. Ry. Co.

Spencerport, N. Y.—The Albion Ry. Co. is stated to have secured right of way through Spencerport and Middleport.

Troy, N. Y.—The Forest Park Ry. Co., of Troy, has been incorporated, with a capital of $20,000, to build and operate an electric railway, 2 miles long, from Pawling Ave. to the town of Brunswick. Directors: Jos. A. Leggett, Arthur G. Sherry, and others, all of Troy.

Elmira, N. Y.—The Elmira & Waverly Electric R. R. Co. is stated to have secured the entire right of way for its line from Elmira to Waverly, and work on its construction will probably soon commence. H. B. Rhymer, Pres.; John M. Diven, Secy.

Irvington, N. J.—The Council has passed on second reading the ordinance granting a franchise to the Essex Cross Ry. Co.

Atlantic City, N. J.—The Atlantic City & Suburban Traction Co. is stated to have secured a franchise to extend its line through Egg Harbor Township.

Weehawken, N. J.—The New York Central R. R. is reported to have contracted with the General Electric Co. and Westinghouse, Church, Kerr & Co. for the installation of steam engines and electric alternating current generators at its Weehawken station. The company is reported to be expending about $50,000 on its electrical plant at this point.

Mt. Holly, N. J.—The People's Traction Co. is stated to have petitioned the County Bd. of Freeholders for a franchise to construct an electric railway between Mt. Holly and Burlington.

New York, N. Y.—The Mayor has signed the ordinances passed last week granting tunnel franchises to the Pennsylvania R. R. Co. and the New York & Jersey Tunnel Co.

New Martinsville, W. Va.—Homer McKinley, of Salem, W. Va., is reported interested in the construction of an electric railway to connect Salem, Clarksburg and probably New Martinsville.

Rockford, Ill.—It is stated that the Southeastern Wisconsin Electric Ry. Co. will probably construct a line to connect the Rockford, Beloit & Janesville line with Green Bay. G. W. Knox, of Chicago, is reported interested.

Byesville, O.—The City Council is stated to have granted a franchise to the Consolidated Ry. Co. of Cambridge

Genesco, Ill.—The Council is stated to have granted a franchise to the Kewanee, Cambridge & Geneseo Ry. Co.

Battle Creek, Mich.—The City Council is stated to have granted a franchise to the Jackson & Battle Creek Interurban Ry. Co.

Toledo, O.—The Toledo, Fostoria & Findlay Ry. Co. is reported to be preparing to extend its line. A new power house will be constructed at some point between Toledo and Fostoria. W. Nusbaum, Ch. Engr., Cincinnati.

Evansville, Ind.—Chas. Laval, of Evansville, is reported interested in the construction of an electric railway from Evansville to Henderson.

The Evansville & Newburg Interurban Ry. Co. will probably be extended to Rockport, a distance of 23 miles. G. Muhlhausen, Supt., Evansville.

New Albany, Ind.—The City Council is stated to have granted a franchise to the New Albany St. Ry. Co.

Indianapolis, Ind.—Chas. L. Henry is reported interested in the construction of an electric railway from Indianapolis through Rushville to Connersville.

Moorhead, Minn.—The Council is stated to have granted a franchise to Attorney Morrill, of Fargo, N. D.

Duluth, Minn.—A. C. Volk & Co. are stated to have petitioned the Council for a franchise to construct an electric railway in West Duluth, about 6 miles in length.

Toledo, O.—The Toledo, Port Clinton and Lakeside Ry. Co. is reported formed, with a capital of $10,000, to construct an electric railway with terminus at Toledo and Lakeside; length of proposed line 50 miles. Incorporators: H. R. Klauser, L. E. Flory, and others.

Creston, Ia.—The Collins Construction Co., of Chicago, Ill., is stated to have secured the contract for constructing the railway for the Creston Electric Light, Ry. & Power Co. from Creston to Winterset, the road to be completed by Jan., 1904.

St. Louis, Mo.—The Elevated Electric Ry. Co., of St. Louis, is reported incorporated, with $100,000 capital, by John Dwyer, Chas. Erd, and others, to build and operate a double track elevated street railway.

Bonner Springs, Kan.—The Iola Electric R. R. Co. is stated to have secured a franchise to extend its line to Bonner Springs.

Paris, Ky.—The Bourbon Fiscal Court is stated to have granted Claude M. Thomas, C. C. Clark and Webb Bratton a franchise to build an electric line from Paris along the Paris, North Middletown, Flat Rock, Plum Lick and Cane Ridge turnpikes.

Jackson, Miss.—A company is reported formed, with a capital of $200,000, to construct a belt road around the town, and through the suburbs. J. B. Harris, Pres., J. J. Coman, Secy.

Nashville, Tenn.—Engineers representing Ford, Bacon & Davis, of New York, N. Y., are stated to have arrived in Nashville to take up the work of rebuilding and re-equipping the Nashville St. Ry. The work will require 1½ years and will cost $1,500,000.

Purcell, Ind. Ter.—The Purcell & Lexington St. Ry. Co. has been incorporated, capital $100,000, to build and operate an electric railway between Purcell and Lexington, Okla. Ter. Wm. T. James, Thos. C. Woods and J. F. Sharp, are the incorporators.

Omaha, Neb.—The entire street railway system of Omaha and South Omaha, the Omaha and Council Bluffs bridge which operates the street railways of Council Bluffs and the Lake Manawa & Courtland Beach suburban lines are reported to have consolidated. The consolidated lines comprise 200 miles of track. The capital of the new company will be $6,000,000, and Frank Murphy, present head of the Omaha system, will be president of the combined companies. General office to be located in Omaha. It is reported that about 200 miles of suburban electric lines will be constructed in Eastern Nebraska and Western Iowa. Seligman & Co., Bankers, of New York, N. Y., will finance the new company.

RAILROADS.

Windsor Locks, Conn.—The Windsor Locks R. R. Co. has been incorporated, with a capital of $40,000, to construct a railroad about 4 miles in length from East Granby to Windsor Locks. Incorporators: Chas. E. Perkins, Hartford; W. W. Viets, East Granby; L. P. Bissell, of Suffield, and others.

New Berlin, N. Y.—The Mohawk & Hudson Valley R. R. Co. is reported to have been formed to construct an extension of the Unadilla Valley R. R. from New Berlin to Oneonta, a distance of 33 miles; capital, $500,000. Directors: Fred. F. Culver, Granville Whittlesey, Chas. S. Bartow, and others, all of N. Y. City.

Philadelphia, Pa.—The Select Council has passed an ordinance authorizing the construction of a southern terminal in Delaware Ave. by the Rapid Transit Co. and granting the company the privilege of constructing a loop from Broad and Market Sts. to Chestnut or Walnut, and east in either of these streets to 5th and Arch, returning to Broad St.

The Council on Dec. 22 passed an ordinance granting the Pennsylvania R. R. Co. permission to construct an elevated road for freight in West Philadelphia. W. H. Brown, Ch. Engr., Philadelphia.

Erie, Pa.—It is stated that the Erie & Pittsburg R. R. will construct a new line to Erie, Pa., from Thornton Junction, a distance of 20 miles. This road is reported to be controlled by the Pennsylvania Co. Thos. Rodd, Ch. Engr., Pittsburg.

Summit, N. J.—It is stated that surveys have been made for an extension of the New Orange Four Junction R. R., from New Orange to Summit, 5 miles. D. F. Dankel, Supt., New Orange.

Cincinnati, O.—Local press reports state that 28 crossings on the Pennsylvania R. R. will be abolished by either elevating the tracks over the streets or constructing viaducts over the tracks at 14 different points. The plans contemplate the extension of some streets, the closing of others, the purchase and condemnation of property, lowering the grade of streets, and constructing 7 miles of elevated railway track. W. H. Brown, Ch. Engr., Philadelphia.

Burnsville, W. Va.—Later press reports state that Gooch, Rinehart & Dennis, of Staunton, Va., have secured the contract for constructing 71 miles of railroad for the Wabash R. R. Co. from Sandy Bend to Burnsville; cost reported to be $2,500,000.

Patrick McGovern, Roxbury	2.90	12.50	25.00	0.50	0.25	0.75	34,300
H. P. Nawn, Roxbury*	3.50	10.00	8.00	0.65	0.30	0.60	33,420

*Awarded contract.

New York, N. Y.—Bids will be received Jan. 2 by McDougall Hawkes, Comr. of Docks, for furnishing and delivering about 10,000 bbls. of Portland cement. Bids will be received Jan. 8 by the Park Bd. for laying out Thomas Jefferson Park; also on same date for furnishing material and erecting a pavilion in Wm. H. Seward Park. Wm. R. Willcox, Chmn. Comrs. of Parks.

New York, N. Y.—Bids will be received Dec. 30 by Thos. Sturgis, Fire Comr., for furnishing material for constructing and delivering fire pumps for a new fireboat.

Brooklyn, N. Y.—Bids are wanted Dec. 29 (extension of date) for furnishing and erecting wrought iron picket fence along Shore Road and iron gates in New Lots and Linton Parks, for furnishing and delivering 6,600 cu. yds. of Hudson River road gravel in parks and parkways as required, for furnishing and delivering 6,000 cu. yds. of crushed trap rock and 3,000 cu. yds. of trap rock screenings on parkways, all in the Boro. of Brooklyn; for furnishing and delivering 7,550 cu. yds. of blue limestone and 6,700 cu. yds. of blue limestone screenings on parks and parkways in the Boros. of Brooklyn and Queens. Wm. R. Willcox, Chmn. Park Comrs., N. Y. City.

Jersey City, N. J.—The Board of Finance on Dec. 17 passed the resolution placing $60,000 at the disposal of the Street & Water Bd. to pay for the additional land to be purchased to enlarge River View Park, on Ogden Ave.

Philadelphia, Pa.—The Finance Com. of Council has recommended an appropriation of $100,000 for sand for the filtration plant.

Brooklyn, N. Y.—The only bidder Dec. 24 for 42,000 cu. yds. of dredging in Gowanus Canal, etc., was the Morris & Cummings Dredging Co., 17 State St., at 71 cts. per yd., which is considered too high.

Augusta, Ga.—The Governor is stated to have approved the bill authorizing the construction of a dam across Savannah River, above Augusta.

Lorain, O.—It is stated that the Baltimore & Ohio R. R. Co. will make extensive improvements to its docks in Lorain. Engineers are preparing plans for the work.

Cincinnati, O.—It is stated that about $60,000 will be expended on improvements at the Zoological Garden.

Laporte, Ind.—The contract for straightening part of Kankakee River, between Laporte and Starke Counties, is stated to have been awarded by the Kankakee Reclamation Co. to Pollard & Goff, of Champaign, Ill., and John McAndrews, of Bradley, Ill., for about $81,000.

Memphis, Tenn.—H. N. Phsrr, of Memphis, Ch. Engr. of the St. Francis Levee Bd. of Ark., writes that it is proposed to build a levee at Walnut Bend, Ark., on the Mississippi River, to cost $90,000. Work will be done during next season. Capt. E. W. Lucas, Corps Engrs. U. S. A., of Memphis, will be engineer in charge. He also states that it is proposed to construct 2 miles of revetment protection for the levee at Kemps Bend, just below Baton Rouge, La., and this work will probably be started next season, and will cost about $200,000. Capt. Chas. S. Bromwell, Corps Engrs. U. S. A., 3232 Prytania St., New Orleans, La., will have charge of this work, and should be addressed for further information.

NEW INDUSTRIAL PLANTS.

The John Zunner Health Beer Co., 10 Booth's Block, New Britain, Conn., will erect a 2 and 3-story brewery, 84 ft. square, to have an annual capacity of 25,000 to 50,000 bbls.

The Siluria Cotton Mill Co., McGowan Building, Birmingham, Ala., expects to erect a 2-story mill about 250x75 ft., to contain 10,000 spindles. The capacity of the power plant, when completed, will be 600 H.-P., and at present will probably consist of the high-pressure side of a cross compound horizontal engine direct connected to a 450-Kw. generator. T. C. Thompson, Pres.; Brevard D. Miller, Secy. & Treas.

August Tiesse, 801 N. Second St., Clinton, Ia., is interested in the erection of a 30,000-bbl. brewery.

James D. Shelby, Junction City, Ky., wishes to correspond with makers of machinery for canning and broom factories.

Oscar Krebs, Ottawa, O., will install a 5-ton foundry.

Spencer Kellogg, 375-381 Ellicott Square, Buffalo, N. Y., will erect a linseed-oil plant having a yearly output of 300,000 bbls. and 100,000 tons of linseed-oil cake. The plant will be driven electrically.

The Bittner Fire Clay & Brick Co., New Castle, Pa., expects to erect a plant having a daily capacity of 40,000 at Volant, Pa. The capacity of the power plant will be 200 H.-P.

Kaltenbach & Griess, Cleveland, O., are consulting engineers for the new plant to be erected by the Interstate Engineering Co., of that city.

Neil C. Sullivan, Longmont, Colo., writes that the Havemeyers will build a 600 or 1,200-ton beet-sugar plant. The site has been bought and beets contracted for.

BUSINESS NOTES.

The Waterloo, Ia., Gasoline Engine Co. is to be reincorporated with an increase of capital stock from $40,000 to $150,000. The new arrangement will include the consolidation of the company with the Davis Gasoline Engine Co. into the Waterloo Motor Works, which will make automobiles, and stationary, portable and pumping gasoline engines.

The Maiden Creek Portland Cement Co., principal office at 15 Exchange Place, Jersey City, N. J., has been incorporated with a capital of $1,000,000 by K. K. McLaren, Raymond Newman and H. S. Gould.

The firm of Snare & Triest, 39 Cortlandt St., New York, contracting engineers, has been incorporated with a capital of $600,000 for the purpose of increasing facilities for handling its business. The directors are Frederick Snare, W. G. Triest and H. M. Dunn.

The Ball Engine Co., Erie, Pa., reports the following among recent sales: 125 H.-P. for the Osgood, Ind., Light Co.; 100 H.-P. for the American Car Co., St. Louis, and 200 H.-P. for the Arkansas & Texas Consolidated Ice & Coal Co., Marshall, Tex.

The American Blower Co., Detroit, reports a number of large orders on its books, among which it mentions one from the Geo. H. Hammond Co., Chicago, for sixteen large steel-plate fans; three from the Lehigh Valley Coal Co., New York, for forced draft fans for Centralia and Wilkesbarre, Pa.; induced draft apparatus for the Corinth, N. Y., mill of the International Paper Co.; Princeton, N. J., University, and the Binghamton, N. Y., Electric Light & Power Co.

The Pittsburg Coal Co. has given an order for six 150-H.-P. tubular boilers for its various mines, to the Pittsburg, Pa., Gage & Supply Co. The Penfield, Pa., Coal Co. has also placed an order with this company for a 40-H.-P. Chandler & Taylor engine and a 50-H.-P. horizontal tubular boiler.

The Union Railway Co. is about to build a large sub-station at West Farms, New York City, for which it has purchased from the Westinghouse Electric & Mfg. Co. three 1,000-Kw., 3-phase rotary converters, with starting motors, self-cooling, oil-insulated transformers and A. C. and D. C. switchboards. Transmission will be at 6,300 volts and 3,000 alternations. The A. C. switchboard will be equipped with the new Westinghouse, Type C, oil-break, electrically operated switches, which are being installed in the Bayard Street station of the Metropolitan St. Ry. Co. of New York.

The New England Structural Co. has moved its Boston office from Post Office Square to the eleventh floor of the new building at 110 State St., Boston.
